THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

VOLUME XIV.

FROM NOVEMBER 15, 1884, TO MAY 9, 1885.

LONDON:

Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1885.

ASTOR LIBRARY NEW YORK FEB 28 1893

-14535-

INDEX TO VOL. XIV.

A

Abney, Capt., Recent Researches in Radiation, 402.
Accident at Messrs. Bolckow's Works, 69.
Accidents from Currents, 49.
Accumulators (*see* BATTERIES, SECONDARY).
Adams, Dr. W., Evolution of the Electric Railway, 166, 210, 227, 247.
Adams, W. G., Alternate Machine as a Motor, 75, 93.
Adams, W. G., Experiments at South Foreland, 277.
Africa, South, Cable Service to, 502.
Alternate Current Machine as a Motor, 75, 93.
Alternating Currents, by T. H. Blakesley, 199, 258, 287, 326, 373, 411, 510.
Alternating Currents, by J. Hopkinson, 11, 35, 54.
America, Electric Lighting in, by Dr. Fleming, 287.
America, Electric Lighting in, by W. H. Preece, 68, 95, 115.
America, Incandescent Lighting in, 473.
America, Underground Wires in, 397.
American Sectional Underground Company's System of Conductors, 315.
Anderson, Sir J., on a Cable between Australia and Natal, 515.
Anderson's Conduit for Underground Wires, 315.
Anglo-American Brush Company (Leading Article), 242.
Antwerp Exhibition, 200.
Arc, The Silent, by A. C. White, 56.
Arc Lamp, Crompton's, 286.
Arc Lamp, New, 127.
Aron, Dr., His Coulomb Meter, 189.
Atlantic Cable Broken, 221.
Australia, Progress in, 537.
Australia, Reduction of Press Tariffs to, 132.
Australia and Natal, Proposed Cable between, 515.
Ayrton and Perry, Professors, Most Economic Potential Difference for Incandescent Lamps, 309, 347.

B

B. T. K. Storage Batteries, Report by Prof. Forbes, 499.
Baily's Equilibrium Apparatus, 274.
Bandsept, A., Mechanics of Electrolysis, 332, 374.
Batteries, Constant, Danger of, 265.
Battery, Portable, for Mines, 29.
Battery, Primary (*see* VOLTAIC CELL).
Battery, Secondary, The B. T. K., Report by Prof. Forbes, 499.
Battery, Secondary, The Garassino, 226.
Bell Indicator, Electrical, 9, 493.
Belting, Influence of Centrifugal Force on, 13, 34.
Berlin, Electricity in a Café in, 473.
Bidwell, Shelford, Changes Produced by Magnetisation in the Length of Metal Rods, 536.
Biographies with Portraits :—
  Brush, C. F., 66.
  Crompton, R. E. B., 26.
  Garnett, William, 198.
  Smith, Willoughby, 238.
  Spagnoletti, C. E., 218.
  Thompson, S. P., 126.
Blakesley, T. H., Alternating Currents, 199, 258, 287, 326, 373, 411, 470, 510.
Bollmann, Recent Improvements in Dynamo Machines, 529.
Brighton Line, Electric Lighting on, 49.
Brooks's Underground Conduit, 316.
Brush, C. F., Biography of, 66.
Business Notices, 424.

C

Cable, Atlantic, Broken, 221.
Cable Service to South Africa, 502.
Cable between Australia and Natal, Proposed, 515.
Cable Ship "Electra," 260.
Cable Ship "Magneta," 108, 154, 472.
Cable Stories Retold, by F. C. Webb, 67, 513.
Cables, Law Relating to Protection of, 201.
Cables and War (Leading Article), 474.
Central Station Lighting, 287.
Centrifugal Force, its Influence on Belting, 13, 34.
Chamberlain, J., Deputation to, re Electric Lighting Act, 38.
Cincinnati Electrical Society, 226.
Clemenshaw, E., Spectrum Analysis, 274, 402.

COMPANIES' MEETINGS, REPORTS, &c. :—
  Anglo-American Brush, 120, 136, 251, 276.
  Anglo-American Telegraph, 251, 296.
  Australasian Electric Light, 169, 382, 404.
  Brazilian Submarine, 524, 539.
  British Insulite, 299.
  Brush, Midland, 99, 170.
  Compagnie Internationale des Téléphones, 169.
  Consolidated Telephone, 117, 192.
  Cuba Submarine, 232, 250.
  Direct Spanish Telegraph, 424, 442.
  Direct United States, 251, 271.
  Dundee and District Telephone, 251.
  Eastern Extension Telegraph, 504, 522.
  Eastern Telegraph, 232, 249, 273.
  Edison and Swan Electric Light, 18.
  German Union Telegraph, 404, 423, 425.
  Great Western Electric Light, 80, 98, 138.
  Gülcher Electric Light, 78.
  India Rubber, Gutta Percha, &c., 320, 339.
  Indo-European, 488, 523.
  Lancashire Maxim-Weston, 320.
  Maxim-Weston Electric, 318.
  Montevidean and Brazilian Telegraph, 424.
  National Company for Distribution, &c., 299.
  Oriental Telephone, 100, 138, 504, 523.
  Provincial Brush, 137.
  Railway and Electric Appliances, 79.
  Reuters, 503.
  South African Brush, 277.
  South Eastern Brush, 300, 340, 358, 402.
  Submarine Cables Trust, 524.
  Submarine Telegraph, 300, 317.
  Swan United, 96, 119.
  Telegraph Construction and Maintenance, 340, 357.
  Telephone Company of Ireland, 508.
  Union Electric Light, 340.
  Western and Brazilian Telegraph, 212, 231.

Condensers, Request for Data, &c., 350.
Conductors for Electric Lighting, 287, 310.
Conductors, Multiple Systems, by W. H. Snell, 412.
Conduits, Underground, shown at Philadelphia, Report on, 315, 335, 378.
Consolidated Telephone Company, Action against by Hollings, 212.
Constants, Voltaic and Thermo-Voltaic, by Wright and Thomson, 17.
Continental Underground Cable Campany's System, 335.
Cores, Induction in, by O. Heaviside, 7, 28, 47, 106, 148.

CORRESPONDENCE :—
  Abbott, W., Anglo-American Telegraph Company, 295.
  Accident at Healtheries, 331.
  Adams, W. G., Watt and Horse-power, 31.
  Alternate Current Machines, 32.
  Anderson, Sir J., Proposed Cable between Western Australia and Natal, 515.
  Anderson and Munro, Domestic Lighting, 475.
  Andrews, H., Battery for Electric Lighting, 153.
  Angelina on the Watt, 52.
  Anglo-American Telegraph Company, 295.
  Animal Electricity, 311, 475.
  Arc Lighting, Multiple Wires for, 453.
  Arc, The Silent, 71, 112.
  Australia and Natal, Proposed Cable between, 515.
  B. T. K. Batteries, Prof. Forbes' Report on, 516.

CORRESPONDENCE *(continued)*:
  Bailey, H. C., Battery for Electric Lighting, 188.
  Ball's Unipolar Machine, 8.
  Balmain's Paint for Electric Light Fittings, 452, 475.
  Bate, D. C., Cures by Wooden Magnets, 295.
  Batteries, Primary :—
    For Electric Lighting, 153, 188.
    The Papp Chloride of Iron, 332.
    The Skrivanow, 352, 395.
  Batteries, Secondary :—
    The B. T. K., Prof. Forbes' Report on, 516.
    Cheap Wanted, 111, 132.
    The E. P. S., 152.
  Bennett, A. R., Induction in Telephone Circuits, 73.
  Berthoud-Borel Cable, The, 153.
  Bituminous Composition for Mains, 476.
  Blackpool Electric Tramway, 415, 452.
  Blakesley, T. H., Personal Safety and Electric Currents, 203.
  Bosanquet, R. H. M., Electro-Magnets, 291, 351.
  Brakes, Best Form of, 207.
  Brass, Electro Deposition of, 112.
  Brooks's Underground Wire System, 415.
  Brown, A. C., New Induction Telegraph, 396.
  Cable between Australia and Natal, Proposed, 515.
  Campbell, R., Electric Lighting Act, 51.
  Chloride of Iron Battery, 332.
  Conductors, Bituminous Composition for, 476.
  Conductors, Correction of Prof. Forbes's Paper on, 188, 207.
  Cox-Walker Lampholder, 371, 396.
  Coxworthy, Franklin, Electrical Condition *v.* Radiant Heat, 455.
  Crompton, R. E., Paying for Specifications, 92.
  Crookes, W., The Gülcher Company, 92.
  Crossley, L. J., Telephoning Sermons, 188.
  Cuff, J. C., An Index, 31.
  Cures Effected by Wooden Magnets, 295.
  Currents, Electric, and Personal Safety, 150, 188, 203, 223, 243, 268, 293, 312, 331, 352.
  Davey Motor, The, 206, 224, 246, 269, 294, 312, 332.
  Davy, Dr. Edward, 313.
  Domestic Lighting, 189, 452, 475.
  Drexler, F., Organ Playing by Electricity, 415.
  Duncan, J. B., Fluorescence or Phosphorescence, 151.
  Duncan, J. B., Peculiar Behaviour of Glow Lamps, 453.
  Correspondents, Answers to, 50, 70, 182.
  Dynamos :—
    Alternate Currents, 32.
    Ball's Unipolar, 8.
    Self-regulating, 52, 71.
    Victoria 10-lighter, 8.
    Winding Field-magnets of, 132, 189, 206, 224, 245, 270, 291, 331, 351.
  Electric Light, Failure of, 331.
  Electric Light Wires, Dangers to, 8.
  Electric Lighting Act Committee, 131, 151.
  Electric Lighting and the Board of Trade, 51.
  Electric Lighting in America, 92.
  Electric Lighting at a Profit, 51.
  Electric Lighting, Small Motor for, 206, 224, 246, 269, 294, 312, 332.
  Electric Tramway, Holroyd Smith's, 415, 452.
  Electrical Condition *v.* Radiant Heat, 455.
  Electrical Condition *v.* Recent Science, 533.
  Electricity developed by Contact of Similar Metals, 294, 313.
  Electrische Beleuchtung, Die, 73.
  Electro-magnets, 132, 189, 206, 224, 291, 331, 351.
  Esson, W. B., The Electric Arc, 112.
  Exhibition, The Inventions, 452.
  Exhibition at New Orleans, 452, 475.
  Failure of Electric Light, 331.
  Fawcett, Henry, 31.
  Fels, A., Telephone in Paris and Buenos Aires, 415.

THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

No. 1.—Vol. XIV. SATURDAY, NOVEMBER 15, 1884. Price 4d.

NOTES.

Telegraph Appointment.—Mr. T. Isley, telegraphist at Norwich, has been appointed Postmaster of East Grinstead.

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 7th November amounted to £3,800.

Turin Exhibition.—The Eastern Telegraph Company has been awarded at the Turin Exhibition the *diploma d'onore*, which is the highest possible honour.

Electric Railway at Nuremberg.—An electric railway is projected along the picturesque *anlage*, between Nuremberg and Fürth, to be executed by Siemens and Halske, of Berlin.

Electric Light at Barcelona.—La Sociedad Española de Electricidad has fitted twenty Gramme arc lamps, driven by a Gramme dynamo, to the large shop known as El Siglio, at Barcelona.

Western and Brazilian Telegraph Company.—The traffic receipts for the week ending 7th Nov., 1884, were £3,034, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Demagnetisation of Watches.—*Kosmos* advises that a magnetised watch be placed in the centre of a metallic spiral traversed by alternate currents, which should be very intense at first, and then gradually diminish in intensity until they become *nil*.

Platino-Brazilian Telegraph Company.—The directors have decided to declare an interim dividend, free of income-tax, of 1s. 3d. per share, payable on and after the 17th inst. The transfer books will be closed from the 11th to the 17th inst., both days inclusive.

Telegrams for Perim.—We learn from a Post Office circular of the 11th inst., that telegraphic communication has been established with the Island of Perim, China, and that telegrams are accepted for that place by the Eastern Company and the Submarine Company, at 3s. 9d. a word.

Temporary Lighting.—The Electrical Power Storage Company recently lighted the private residence, at Blackheath, of Mr. Yarrow, the well-known launch builder. We understand this company is making a speciality of temporary lighting, for which their batteries are admirably adapted.

Domestic Lighting.—The Electrical Power Storage Company has lately carried out an installation at the residence of Mr. Phipps, architect, of Mecklenburgh-square, consisting of 40 Swan lamps, supplied by the E.P.S. accumulators, the dynamo being driven by a 1 horse-power Otto gas engine.

New Postmaster-General.—No decision has yet been officially announced with regard to the office of Postmaster-General, rendered vacant by the death of Mr. Fawcett; but it is generally understood that Mr. Shaw-Lefevre will succeed to the position, with (the *Daily News* thinks) a seat in the Cabinet.

G. W. R. Electrical Contracts.—Mr. H. Thorpe, of Theobald's-road, W.C., patentee of the new semaphore indicator illustrated on another page, has secured part of the Great Western Railway contracts, consisting of needle instrument details, gongs, tapper bells, and various electrical sundries.

Ireland Outdone.—In a manifesto addressed by their leaders to the Skye crofters, the following are among the "Rules for Guidance in the Struggle for Freedom from Landlord Tyranny":—"Cut down the telegraph wires and posts, carry away the wires and the instruments. Stop the mail carts, destroy the letters, &c."

Personal.—We understand that Mr. Robert Ord Ritchie (late manager of Messrs. Woodhouse and Rawson's installation department) has been taken into partnership by Mr. A. Thompson, in his electrical and general engineering business, which will hereafter be carried on at 14, St. Swithin's-lane, under the title of Thompson and Ritchie.

The Spanish National Company's Cables.—We are informed that the Silvertown Company has received a telegram from Mr. Robert Kaye Gray, their engineer-in-chief, announcing the completion of the Gran Canary-Lanzarote cable, by their ss. "Silvertown" on Wednesday, the 5th inst. All well on board. The "Silvertown" left Greenhithe on the 24th ult.

Meteorological Society.—At the meeting to be held on the 19th inst., at 7 p.m., the following, among other papers, will be read:—"On the Injury by Lightning (April 28th, 1884) to the Monument to the first Duke of Sutherland at Lilleshall, Shropshire," by C. C. Walker; "On the Mechanical Characteristics of Lightning Strokes," by Colonel the Hon. Arthur Parnell.

Suez Canal and Electric Light.—Among the questions discussed by the Consultative Committee of English Directors of the Suez Canal appointed for the protection of British interests in the Canal, which held its first meeting on Tuesday, at the office of the directorate, 1, Whittington-avenue, Leadenhall-street, Mr. C. M. Palmer occupying the chair, was that of the electric lighting of the vessels passing through the Canal.

Electric Lighting at the Bank of England.—The lighting of a portion of the Bank of England by means of a hundred and sixty 20-candle lamps, carried out by the Electrical Power Storage Company some twelve months back, has

Digitized by Google

given every satisfaction. The installation has worked throughout without any stoppage; and the accumulators, from which the current is entirely supplied, have not been in any way renewed.

AMIENS INDUSTRIAL SOCIETY.—In the programme of questions on which competitive communications are invited, we find that a gold medal will be awarded for the best paper on a dynamometer to supersede the Prony brake, but requiring a less inconvenient installation. Foreigners are admitted to compete; and MSS., which must be in the French language, are to be sent to the president, Société Industrielle, Amiens, not later than 31st May next.

EARTH CURRENTS.—M. Blavier concludes as follows a communication on this subject made to the Société Internationale des Electriciens:—"The study of earth currents is calculated to lend valuable assistance to scientific research connected with the physical constitution of the eaath. This study should be generalised and carried on in magnetic observatories, which might be done independently of the telegraph staff, since lines of a few kilometres' length are sufficient to permit of the observation and registration of these currents."

THE BRITISH ASSOCIATION.—The General Committee of the British Association for the Advancement of Science met at the Royal Institution on Wednesday afternoon, when Sir Lyon Playfair was appointed president-elect for the next meeting, which will be held at Aberdeen, commencing on the 9th of September, 1885. Invitations for 1886 were presented from Birmingham, Bournemouth, and Manchester. After hearing the representatives of the different places, it was unanimously resolved to hold the 1886 meeting in Birmingham.

ELECTRIC LIGHTING ACT.—At a meeting of the Edison and Swan United Electric Light Company, held on Tuesday afternoon, Mr. J. S. Forbes, the chairman, said that the effect of the Electric Lighting Act and the Provisional Order was to make electric lighting impossible. He also stated that, although they had made a loss of £28,000 last year, the profit and loss account for the first quarter of the present financial year showed a profit of £750, and there was reasonable ground for believing that they had a good future before them. A full report of the meeting will be found in another part of our present issue.

ELECTRIC LIGHT AT PHILADELPHIA.—The American Electric Construction and Supply Company have been awarded the contract for wiring and putting in the plant for 450 incandescent lamps at Messrs. Folwell Brothers' new and extensive woollen mills in Philadelphia. The system is the Brush-Swan. They have just completed the installation of an extensive plant at the Pequea Mills in same city. The mains for the 450 lights will be four strands of No. 0 wire. The whole work is under the supervision of Mr. Arthur Kitson, formerly general superintendent of the United States Electric Light Company of Pa.

NEW PRIMARY BATTERY.—M. Senet has brought out a new battery, which depends on the use of a double sulphate of ammonia and sesquioxide of iron. The rectangular cell is of wood, containing the solution of alum and two carbon plates, while a porous jar contains water acidulated by one-tenth of sulphuric acid, and a plate cast from zinc and mercury melted together. This battery is said to be very constant, and has an E.M.F. of 1·7 volt. This depolariser has the advantage of costing only 1d. or 1½d. per lb., while its decomposition supplies the sulphuric acid necessary for attacking the zinc.

LORD MAYOR'S DAY.—The *Pall Mall Gazette* complains that on Monday "so dense was the crowd that a telegram despatched from the Post Office to Northumberland-street took exactly two hours and three-quarters in delivery, being despatched at a quarter past one and being delivered together with sixteen others at four o'clock. That is to say, the message took about six times as long by telegraph as it would have taken an ordinary messenger to have walked the whole distance if the road had been clear." On this we would remark that as men of business make their arrangements in anticipation of a block to traffic, it is rather remarkable that men of the Press do not exercise their foresight in a similar way.

ELECTRIC LIGHT AT THE ANTWERP EXHIBITION.—The executive committee of this exhibition has sent circulars to a large number of electric lighting companies asking prices and conditions for installing and maintaining the lights during the exhibition. The price is asked for per carcel-hour, or say for 10 candle-power per hour, supposing the motive power to be supplied without cost to the lighting companies. All the leads are to be covered and placed overhead, while the exhibitors are to receive an indemnity of 1 franc (nearly 10d.) for every kilogramme (2·2lb.) of copper employed. Tenders were to be sent in by 15th inst., and the contracts will be let by the committee, acting under the advice of a sub-committee consisting of Messieurs Dery, Dumont, Evrard, Gérard, Gody, and Wijbauw.

LIGHTNING CONDUCTORS IN SCANDINAVIA.—Professor Mohn, of Christiania, who was commissioned by the Swedish Government to hold an official inquiry as to the degree of protection afforded by lightning conductors, ascertained that lighthouses, telegraph stations, and other buildings, very much exposed, but provided with lightning conductors, suffered considerably less than the churches, which are in Norway generally not protected against lightning. Out of a hundred churches struck, only three were provided with lightning conductors. In one, the conductor of which was in good condition, no damage was done. In the second, the conductor, which was of zinc, was melted. In the third, the conductor was eaten by rust where it entered the soil; and the church was set on fire.

PURE CARBON.—M. Jacquelain has endeavoured to procure a pure carbon for electrical purposes that should be as hard and as conductive as gas carbon. He first takes gas carbon, which he submits to four processes: (1) Treatment with dry chlorine at a red heat for thirty hours; (2) treatment with hot alkali for about three hours; (3) immersion in hydrofluoric acid—one to two of water—at a temperature of 15° to 25°; (4) carbonisation by heating strongly in the vapour of a high boiling hydro-carbon—for commercial purposes gas tar will do well. All these operations may be performed after the carbon has been cut into sticks. By these processes, which do not seem to be new in any particular, the *Scientific American* says, the impurities have been reduced to a minimum, and a good pure carbon is obtained.

A TOWN ELECTRICALLY LIGHTED BY A STREAM.—At Bellegarde, in France, M. Dumont, a manufacturer, has thrown a dam across the Valserine, a stream yielding 1,100 gallons per second, and affording, with 165ft. fall, an hydraulic power of at least 2,000 horses; a 600 horse-power turbine is already at work, and drives, among other machines, two Gramme dynamos, the current from which is led direct, by copper conductors placed on poles, to Edison incandescent lamps distributed about the town. The lighting is brilliant enough, but requires a regulator, and also proper distribution, so as to be able to switch individual or series of lamps on or off. The dynamos might well be employed during the day for generating current, to be utilised on the spot or transmitted to a distance, as the whole 2,000 horse-power is available.

Digitized by Google

THE PATENT ACT AND THE INVENTORS' INSTITUTE.—At a meeting of the Executive Council of the Inventors' Institute, held at their rooms, Lonsdale Chambers, Chancery-lane, on Monday, the 10th inst., it was resolved "That the first meeting in every month should be devoted to the consideration of the Patents, Designs, and Trade Marks Act of 1883; that the Act should be gone through regularly by sections, and that a report should be drawn up of the result of the discussions, and that visitors should be invited to attend these meetings." The first meeting for the consideration of the Act will take place on Monday, December 8th, the chair being taken at 8 p.m. by Vice-President Admiral Selwyn, when Parts I. and II. as far as Section 7, should time permit, will be discussed. The secretary is authorised to issue a few tickets of admission.

THE ELECTRO-CHEMICAL EQUIVALENT OF SILVER.—A very careful and important determination of the electro-chemical equivalent of silver has been made at the Observatory of the Physical Institute of Wurzburg, and the results are that an ampere current flowing for a second, or a coulomb of electricity, deposits 1·1183 milligrammes of silver or 0·3281 milligrammes of copper, and decomposes 0·09328 milligrammes of water, a result agreeing closely with that of Lord Rayleigh, recently communicated to the Physical Society. An ampere therefore deposits 4·0259 grams of silver per hour; Kohlrausch's value is 4·0824, a value hitherto accepted universally. This value is so useful in measuring electric currents with accuracy, and free from the disturbances of magnetism, &c., that it is eminently satisfactory to find the German value agree with that of Lord Rayleigh, which will probably be adopted by English electricians.

THE ELECTROLYTIC EXTRACTION OF COPPER.—Messrs. Siemens and Halske, of Berlin, have five C_1 machines, each with twelve baths in action, at the Oker Works. Each machine is worked by a water-power of from four to five h.-p., and deposits one kilogramme (2·2lb.) of copper per cell per hour—that is, about 300 kilos. (6cwt.) a day. At the North German Refining Works in Hamburg, six No. 1 Gramme machines and one Wohlwill machine are in operation, precipitating 2,500 kilos. (50cwt.) of copper daily. Oescher and Mesdach have constructed a Gramme machine according to Wohlwill's instructions that yields 800 kilos. (16cwt.) of copper daily. Hilarion Roux, at Marseilles, works with a No. 1 Gramme machine connected with forty baths, having 900 square metres anode surface; the cathodes are only 0·5 mm. thick, and are 5 cm. (2in.) from the anodes. The machine makes 850 revolutions a minute, consumes 240 kilos. (4¾cwt.) of coal a day, and deposits, with 8 volts and 300 amperes, 250 kilos. (5cwt.) of refined copper.

ARTS ET METIERS.—The programme of the course of instruction at the Conservatoire des Arts et Métiers, Paris, for the year 1884-5, has been published, and includes lectures on applied geometry, by Professor Laussedat (director); on descriptive geometry, by Professor Rouché; on applied mechanics, by Professor Tresca (curator); civil construction, by Professor Trélat; applied physics, by Professors E. and H. Becquerel; general chemistry, by Professor Péligot; industrial chemistry, by Professor Girard; applied chemistry, by Professor de Luynes; agricultural chemistry, by Professors Boussingault and Schloesing; agriculture, by Professor Lecouteux; rural engineering, by Professor de Comberousse; spinning and weaving, by Professor Imbs; political economy, by Professor Levasseur; industrial economy, by Professors Burat and De Foville; and commercial law, by Professor Malapert. Strange to say, no lectures on electricity have yet been added, although the University of Liége, in Belgium, has arranged a special course of instruction for electrical students.

EXHIBITION AT THE ALEXANDRA PALACE.—It is really a pity that this building, erected at so much cost, should remain idle and go to rack and ruin. But it is proposed next year to hold an International Exhibition of Arts, Manufactures, Scientific, Agricultural, and Industrial Products, Mechanical Processes, and New Inventions, to be opened about March 31st, and to be kept open for at least six months. It is hoped that, in addition to the ordinary awards made by the international juries, special recognition of these classes of exhibits may be offered by the various guilds, societies, and corporations connected with trade and manufacture. The executive commissioner is Mr. Geo. Collins Levey, C.M.G., and the secretary, Mr. Edgar Ray, the offices of the administration being at 19 and 21, Queen Victoria-street, E.C. Diplomas of honour and honourable mention, as well as for gold, silver, and bronze medals, will be awarded on the reports of the juries, and no restrictions will be placed on selling. Messrs. J. Gavin, Birt, and Co., 27, Leadenhall-street, E.C., have been appointed official agents for the naval and machinery sections, which are intended to form prominent features.

ELECTRIC LIGHT AT THE CHARING CROSS BRIDGE WORKS.—Messrs. Cochrane and Sons, of Westminster, the contractors for widening the Charing Cross Bridge of the South Eastern Railway, being pressed for time, wished to increase the hours of work, and entrusted Mr. J. S. Beeman, M.S.T.E., with the electric light installation. There are five arc lamps of 3,000 to 4,000 candle-power, the current for which is generated by a Crompton dynamo plant, capable of working eight lamps, driven by a 12 horse-power double-cylinder Otto gas engine, which is utilised in the daytime for sawing timber and other purposes. The caissons, in which the excavation takes place under compressed air, are lighted by five incandescent lamps in each, with one outside for the driver. The first portion of this installation was started on Tuesday night last, and gave great satisfaction to both officials and workmen. The arc light was so bright as to interfere with the navigation; and it will be necessary to put up curtains for confining the rays to the bridge. The plant is made movable so that the lamps may be shifted according to the exigencies of the work, in order to permit of the girders being riveted up by night as well as by day. This electric illumination of works in progress shows how contractors may gain several hours of work during the dark days of winter.

UNDERGROUND CABLES.—The Kinetic Engineering Company, of Brook-street, Holborn, has received an order for the underground electric light cables for lighting several streets in Greenock under the Provisional Order obtained by the Police Board. The cables will be of three types, namely, the main cable, consisting of thirty-six strands of copper wire, 1·5 millimetre in diameter; the branch main, of twelve strands of 1·6 millimetre; and the leads for the lamp posts, of one strand 1·2 millimetre in diameter. These cables will be of the Berthoud-Borel type, insulated with Berthoud-Borel material, and encased in a double sheathing of lead, the two sheathings being separated by a layer of gas tar. A conductivity of 96 per cent. and an insulation of 1,000 megohms per mile at the ordinary temperature are guaranteed. These cables will not be laid in any troughs or pipes, but will be tarred and then laid on a layer of fine sand placed in the bottom of the trench, and covered with the same to a depth of about four inches. A plank of wood or layer of bricks will be placed over the sand to indicate the presence of the cable to workmen after-

Digitized by Google

wards taking up the street, and thus prevent its destruction by their tools. Large quantities of these cables have been thus laid in many Continental towns, and give complete satisfaction. This method of laying the Berthoud-Borel cables effects a great saving in time and labour.

LIGHTNING CONDUCTORS FOR MILLS.—In an able and well-digested article on this subject in the *Paper Trade Review* for November 7, the author advises that conductors be not only carefully erected at first, but also regularly tested by means which are now readily available, in order to see that they are continuously effective. He continues:—"Tests are readily taken of a properly erected conductor at any period in a few minutes, but for this purpose a double conductor is required, which, however, is little more expensive than the ordinary rod;" and concludes as follows:—"If it is worth while to attempt the protection of a mill or other building from lightning, it is worth doing properly. The erection of a rod on the chimney shaft, even when well done, cannot be depended on to protect more than the chimney itself; and if put up as it usually is, the hot gases in the chimney offer an easier path for the flash and so create danger. Every salient part of the building, such as the ridges, gable ends, top corners, &c., should be provided with a set of plated points about 6ft. high, and at comparatively short distances from each other. All these points and all the metal work exterior to the building should also be connected in the most secure manner possible, so that the joints shall offer no extra resistance to the lightning rod, which should have a sectional area of at least one centimetre, or, say, a circular half inch."

INCANDESCENT SHIP LIGHTING.—The ss. "Kaikoura," built by Messrs. J. Elder and Co., of Govan, Glasgow, for the New Zealand Shipping Company, which proceeded down the Clyde on the 17th of last month on her trial trip, and left for London at 11:30 a.m. on the 18th inst., was fitted with the electric light, comprising two hundred and forty 20-candle and ten lanterns of three 40-candle Swan lamps each. These lanterns are to be used for loading and discharging cargo. The pendants, designed and made by Messrs. W. M'Geoch and Co., of Glasgow, for oil and electric light combined, are hung from the deck. There are in the first-class dining saloon ten pendants fitted with two electric lamps and one oil lamp each, four in the second-class saloon and one pendant hung above the first and second stairs leading into the saloons. The rest were single-light fittings, of which eleven were combined brackets. The whole of the work has been carried out by Messrs. King, Brown, and Co., of Rosebank Electric Works, Edinburgh, and superintended personally by Mr. W. F. King and his assistant, Mr. H. Lyon. The dynamo is one of Siemens Brothers' compound shunt-wound, driven by a Marshall 33-horse steam-engine, the steam being supplied by the main boilers while at sea, and by the donkey boiler when in dock. The installation was pronounced a perfect success by a large company on board.

INTERNATIONAL TELEPHONE COMPANY.—An extraordinary meeting of the Compagnie Internationale des Téléphones was held at Brussels on the 8th inst., when the President read a report turning upon a numerously-signed letter which had been received by the Council of Administration (or Board of Directors), commencing as follows:—"The persistent depreciation of our shares, the market price of which does not correspond with their actual value, has induced us to seek a combination which will permit of raising the quoted price of our shares without hindering the business of the Company, or injuring its vitality." The method of bringing about this result was referred to several eminent jurisconsults, who all agreed that the present company should be wound up and transformed into a new company bearing the same title, but with a capital of only half the original amount. The report states that it is indispensable to call a new meeting, with a definite programme, so that it can vote successively the proposed modification in the constitution of the company. After the reading of the report, the following resolution was adopted by 43,257 to 1,290 out of 44,517 votes:—"The meeting is of opinion that there is ground for apportioning among the shareholders a portion of the company's *portefeuille* stock, and calls upon the council to deliberate upon the legal and practical means for bringing about this result, while at the same time reducing the nominal capital to its real value." Thus, the International Telephone Company has arrived at a stage already passed through by some telephone companies in this country, and has adopted a remedy to which several electric light companies have found it necessary to resort.

BALTIMORE.—A most pleasant dinner party was given at Johns Hopkins University, on Friday, Oct. 16, by President Gilman to the scientific men who had been brought together by Sir Wm. Thomson's lectures. The happiness of the occasion was only marred by the reflection that it was a farewell event. The feelings of all seem to have been concentrated in Professor G. Forbes, of London, Eng., who broke forth into the following wail:—

The lament of the 21 coefficients in parting from each other and from their esteemed molecule.

An æolotropic molecule was looking at the view,
Surrounded by his coefficients, twenty-one or two,
And wondering whether he could make a sky of azure blue
With platitatic *a b c* and thlipsinomic Q.
They looked like sand upon the shore with waves upon the sea,
But the waves were all too wilful and determined to be free,
And in spite of *n*'s rigidity they never could agree
In becoming quite *subservient* to the thlipsinomic P.
Then *web*-like coefficients and a loaded molecule
With a noble wiggler at their head worked hard as Haughton's mule;
But the waves all laughed, and said a wiggler, thinking he could rule
A wave, was *nothing better* than a sidelong, normal fool.
So the coefficients sighed and gave a last tangential skew,
And *a* shook hands with *b* and *c* and S and T and U;
And with a tear they parted, but they said they would be true
To their much-beloved *wiggler* and to thlipsinomic Q.

Signed (*g*, *f*), a cross-coefficient, now annulled.

Sir William Thomson pronounced the mathematics all right; President Gilman, the verse, and the sentiment was unanimously concurred in.—*Electrical World.*

SOCIETY OF ARTS.—The first meeting of the 131st session of the Society for the Encouragement of Arts, Manufactures, and Commerce will be held on Wednesday, the 19th November, when the opening address will be delivered by Sir Frederick Abel, C.B., D.C.L., LL.D., F.R.S., chairman of the council. Previous to Christmas there will, in addition to the opening meeting, be four ordinary meetings. Among the arrangements already made, the following papers have been promised:—W. H. Preece, F.R.S., "Electric Lighting in America;" Sir J. N. Douglass, "Recent Improvements in Coast Signals;" Professor H. S. Hele Shaw, "The Evolution of Machines." The meetings of the Applied Chemistry and Physics Section, formed in 1874 for the discussion of subjects connected with practical chemistry and its application to the arts and manufactures, and enlarged in 1879, so as to include the consideration of subjects connected also with the applications of

Digitized by Google

physical science to the arts, will take place on the following Thursday evenings, at eight o'clock:—February 12, March 12 and March 26, April 23, May 7 and May 28. There will be seven courses of Cantor Lectures, which originated in 1863, with a bequest by the late Dr. Cantor. The lectures of the third course, on the "Distribution of Electricity," by Professor George Forbes, will be given on the evenings of February 2, 9, and 16. Examinations, open to any person, are held annually by the society, through the agency of local committees, at various centres in the country. The subjects include the principal divisions of a Commercial Education, Sanitary Knowledge, Political and Domestic Economy, and Music. The society numbers at present between three and four thousand members.

JAY GOULD AND THE PRESIDENTIAL ELECTION.—The *Standard's* New York correspondent, telegraphing on Thursday night last week, remarked that "everybody is asking why the returns have been so slow in arriving at New York. The only explanation offered so far is that Mr. Jay Gould, who is a supporter of Mr. Blaine, has the control of the Western Union Telegraph Company's lines. Yesterday, that company posted most inaccurate bulletins upon the Stock Exchange. The Associated Press also spread reports of a very partisan character. The despatches containing the true news were strangely delayed. Some newspapers at last refused to use the news furnished by the Associated Press. Mr. George Green, the Secretary of the Independent Republicans, informs me that his organisation could not get properly served by the telegraph agencies. It is stated that a long conference took place yesterday between Mr. Jay Gould and Mr. Elkins, the manager of Mr. Blaine's candidacy, who was a member of the ring which carried out the Star Route postal frauds. The *New York Herald* further asserts that specific instructions were telegraphed in cipher to the Republican Committee of Indiana that the vote of that State must be cast for Mr. Blaine. It is impossible to describe the public indignation at these exposures." On Friday, commenting on the same subject, the *Pall Mall Gazette* says:—"The rise in Atlantic cable securities appears to be due, in the main, to the additional large receipts of the actual companies during the Presidential contest. Mr. Jay Gould's minions are alleged to have tampered with, or at any rate delayed, some of the messages, and that would be a fact hardly conducive to confidence in the established American cable companies which have working arrangements with the Western Union system of land lines on the other side. Indeed, it would rather tend to divert business to the Mackay-Bennett cables, the new rivals of the Anglo-American and its associated companies." The *Pall Mall* seems to be unaware of the fact that practically there are no "Mackay-Bennett" cables. One of them is certainly broken, and the other is not working for the public, if indeed it is working at all.

ELECTRIC RAILWAYS IN THE UNITED KINGDOM.—We are glad to note that electric railways are making steady progress in this country. The line at Portrush (Ireland) has now been opened twelve months, and has proved so great an attraction that the number of visitors to the Giant's Causeway has been increased tenfold. The line runs through very pretty coast scenery, but is certainly most trying to work, being a succession of heavy gradients and sharp curves, with practically no level ground for the whole six miles. The turbines answer admirably as the source of power; and the River Rush never fails in the dryest seasons. At Newry, a town midway between Belfast and Dublin, another electric railway is being constructed by the Bessbrook Spinning Company, the length of which will be about three miles. Two gangs of men are busily engaged in completing the earth works, bridges, &c., for the platelayers; and the rails have been laid for a considerable distance along the line from the Edward-street terminus. As soon as the rails are laid, Dr. Hopkinson, for the firm of Siemens Brothers, London, will commence the work of erecting the electrical machinery, &c., which will be placed in an old flour mill situate in Millwall, about midway between Bessbrook and Newry. It is believed that the Lord-Lieutenant will visit Newry on the occasion of the opening ceremony, which is expected to take place early next year. Active preparations are also being made to open a system of electrical tramways at Blackpool, which, in anticipation at least, are to surpass everything hitherto attempted; and it is hoped that the work will be completed early in the spring. A deputation of the local authorities of Blackpool recently visited the Brighton Electric Railway. For electric railways at the Novelties Exhibition next year no less than three distinct applications to exhibit have been made; but the limited space available will doubtless prevent their being granted. The Brighton Electrical Railway—it now being the height of the fashionable season—is still crowded for several hours daily, and arrangements are being made to run extra cars, passing on a loop half-way along the line.

LIGHTING OF THE "UMBRIA."—The electrical plant erected on this steamer by Messrs. J. D. F. Andrews and Co., of Glasgow, is probably the largest application of the electric light to a vessel that has yet been attempted. Every detail of the arrangement was carefully studied by Mr. Andrews, who has supplied all the latest improvements in his patented apparatus and specially designed fittings. These were considered generally to form together a perfect success in the matter of ship electric lighting by a large number of visitors who were invited to inspect the vessel previous to starting on her first voyage. There are ninety lights distributed in the engine room, stoke holes, &c., the leads being covered with india rubber and a special composition for resisting sea water, sheathed over all with iron wire, as a substitute for the tube generally used in engine rooms. The engine room lights are divided into two circuits, each with a separate switch; and each stoke hole is also on a separate circuit. The dynamos are connected to the main switch board on the bulk head, close to the engines; and to this switch board are brought the six main circuits which supply the vessel. The six circuits are numbered 1 to 6, starting from the stern, the first circuit supplying the night system, in which there are about two hundred lights including those in the engine room and stoke holes. No. 2 circuit lights the aft portion of the ship; No. 3, midships; Nos. 4 and 5, the main saloon, ladies' saloon, music room, &c.; and No. 6 all lamps forward of the saloon. Each of the main leads is carried to a group of switches at the junction of the main and branch leads, each switch controlling a group of about thirty lights. A simple switch, consisting of a screw, severing connection with the lamp from the ship, which is used as the return, is attached to each lamp; and these switches are under the control of the steward. There are altogether a hundred and three lamps in the main dining saloon, of which eighty-four are hung over the tables in 3-light pendants about 2ft. 6in. from the ceiling. The remainder of the lamps are in small brackets and pendants for giving light over the side seats. The music room, which is over the saloon, has seventeen lamps round the walls and over the piano and organ, while the smoke room is lighted by seventeen lamps, and the remainder are distributed about the ship, a hundred and seventy-two being in the state rooms. The time occupied in the installation did not greatly exceed two months.

THE STEAM ENGINE INDICATOR.—I.

BY AMICE.

The steam engine has now become one of the most important of the machines placed under the care and control of the electrical engineer. It is therefore necessary that electricians should be thoroughly acquainted with all that pertains to the power of this essential motor. With this view, and in response to the wishes of numerous contributors, we recently published a series of articles on dynamometers, and these were so well received that we propose now to deal with the indicator and its uses in a similar manner.

The indicator may be looked upon as a mirror which shows us what is going on in the cylinder of a steam engine, both qualitatively and quantitatively. It is of course equally applicable for the same purpose to any other form of gas or fluid pressure motor. We shall, however, except where specially stated, speak generally of the steam engine.

Like almost all the essentials of the steam engine, the indicator was invented by Watt. He designed it for ascertaining the work done by the steam on a steam engine piston, and although in the hands of modern investigators, and with the aid of thermo-dynamics, it has performed most important services other than that of determining the dynamic value of the work done by steam, it is still most largely used for that more simple purpose.

The work done by a steam engine depends on the velocity of its piston and the pressure by virtue of which it acquires and maintains that velocity, these elements being usually expressed in feet per minute and pounds per square inch. That is to say, in foot pounds per minute. Of these elements the indicator diagram shows primarily one—namely, the pressure, and its function is especially to show the variations in this pressure due to expansion and to other causes of change of pressure during the stroke of the piston, and therefore to show variation of pressure through a distance. If the pressure in the cylinder were uniform throughout the stroke, the indicator diagram would not be required as an exponent of pressure, but it would still be required in some part of the history of every engine, for the purpose of showing whether in any or in what parts of the stroke variation occurred, if at all.

It is necessary here to say a few words on what is meant by work, and how this can be graphically represented. There must be a clear understanding of the connection between the indicator diagram and the indicated work. It must be seen that the indicator diagram only represents graphically the pressure acting on the piston of a steam engine during one stroke. It thus represents pressure and distance, throughout which the pressure acts, and therefore work done; but it does not show at what rate that work was done, and, therefore, not horse-power, inasmuch as the latter is expression for rate of doing work. That is to say, one term in the element, velocity, namely, time, has to be supplied. The diagram shows that pressure acted on the piston throughout the length of a stroke, but whether a century of years or only a second of time were occupied in performing this stroke it does not show. In either case the amount of work done would be the same,* but if it were only accomplished in the century, it would be useless for practical purposes. Thus, to use Professor Tait's definition, "the horse-power of an agent, or the amount of work done by an agent in each second, is the product of the force into the average velocity of the agent." If an agent, as an engine, raises 1,000lbs. through 10ft., it does 1,000 × 10 or 10,000 foot pounds of work, but the power of that engine will depend upon the time it takes to do that work, or its rate of doing work, and the horse-power is the power of doing 33,000 foot pounds of work in a minute, or 550 foot pounds per second.

Of the power of the animal whose capacity for work provides this unit, everyone has a natural conception. The horse is so universally employed for doing work that every man acquires insensibly a notion of the amount of work one or a number will do. Previous to the introduction of the steam engine horses were used to do the work subsequently done by that agent. Watt therefore set to work to find a numerical value for the work done by a good horse in a unit of time, and found it to equal 33,000lbs. raised 1 foot in 1 minute.

A graphic representation of the work done by steam on the piston of a steam engine would, if the steam were admitted at full pressure throughout the stroke of that piston, be afforded by a simple rectangular parallelogram. It would be thus

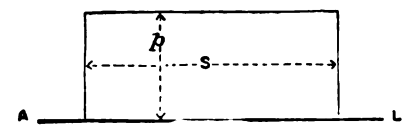

FIG. 1.

in the case of a high pressure non-condensing engine; while in a condensing engine of similar length of stroke and using the same pressure of steam it would be thus

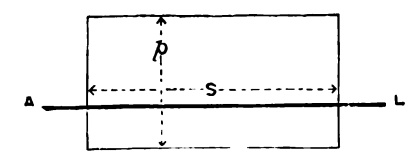

FIG. 2.

In both these diagrams S represents the stroke of the piston and p the pressure acting upon it. The line A – L represents what is, with the high pressure non-condensing engine, the line of no pressure, or what in reality represents the pressure of the atmosphere. The whole of the diagram is formed by steam at a pressure above that of the atmosphere. In the condensing engine it also represents the atmospheric pressure, that part of the diagram which is below that line representing the proportion of the pressure of the atmosphere which is made available as pressure acting on the piston by the formation of a vacuum in the condenser, this pressure being added to the steam pressure acting on the other side of the piston. The popular conception of the action of a vacuum is that of a power of suction which pulls the piston, but its action is due to the removal of atmospheric pressure from one side of the piston, so that the result is equivalent to making the pressure of the atmosphere available for doing work on the other side of the piston.

Before proceeding to the indicator we may define what we want it to show. Assume now that the line A – L in Fig. 3 is drawn on a piece of paper at such a level that it would as concerns non-condensing engines represent the line of no pressure. Although, as above explained, it would represent the pressure of the atmosphere, or say 15lbs. per square inch, this pressure is not available by the non-condensing engine, and is therefore to it a zero pressure, just as it is as respects a steam boiler, the zero point on the steam pressure gauge dial being the point at which the pointer stands when the gauge is subject to the atmospheric pressure. Turning

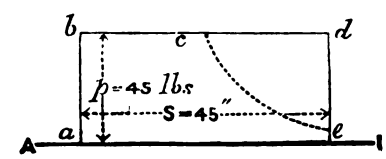

FIG. 3.

to Fig. 3, then, we will assume that the steam pressure from the boiler is such that it gives a pressure, p, of 45lbs. per square inch in the cylinder. Steam being admitted to the cylinder at the commencement of the stroke S of the piston, we may draw a line, $a\ b$, normal to A L, and of such a length that with a convenient scale it represents 45lbs. This, then, is the pressure per square inch acting on the piston at the commencement of the stroke. Assuming that the full pressure steam is admitted throughout the stroke, a line c, parallel with A L, and of a length $b\ d = S$, representing the whole stroke of

* This is not absolutely accurate, but for the velocities occurring in steam engine practice it is not necessary to consider the difference between the work done by the agent which, for instance, raises 1,000lbs. one foot in a second and that which raises 500lbs. in half the time through the same height.

Digitized by Google

the piston, will show the pressure at every part of the stroke made in the direction $b\,d$ (in our case assumed uniform). The piston having reached the end, d, of its stroke, and exhaust being supposed to take place instantaneously, the line $d\,e$ may be drawn, indicating that the pressure at the end of the stroke has fallen to atmospheric pressure, or in this case to zero. The piston now commences the return stroke, and the pressure during this may be represented by the line $e\,a$. A parallelogram is thus completed which, if from an actual engine, would indicate that there was a uniform pressure throughout the stroke, and the indicated horse-power of an engine with a stroke, S, of 45″ = 3·75ft. and cylinder diameter, D, = 20·5in. in diameter, and having an area, A, = 330in., the engine making 50 revolutions, R, per minute, and being double-acting—that is, having steam pressure alternately on each side of the piston—would be

$$\frac{D^2\pi P(S\times 2)R}{33{,}000}=\frac{APR(S\times 2)}{33{,}000}=\frac{330\times 45\times 7{\cdot}50\times 50}{33{,}000}=168{\cdot}7\text{h.-p.}$$

It must here be stated that the full pressure of steam is never admitted throughout the whole stroke, but is cut off, according to circumstances and the kind of work done by the engine, at an earlier part of the stroke, as, for instance, one-half, when the pressure falls as shown by the curved dotted line. The diagram obtained under these circumstances is therefore not a parallelogram. The pressure acting on the piston is not constant. The vertical height of the line $a\,b$ varies at different parts of the distance S, and hence to find the work done during the passage of the piston through that distance, we must divide S into a number of equal intervals, and, assuming the pressure uniform throughout each of these, construct a parallelogram within each interval and the bounding pressure line. The work done is then represented by the combined area of the several small parallelograms. Thus, suppose S is divided into 10 equal parts by 9 intermediate lines. During the first four of these the height $a\,b$ represents, say, 100lbs.; the remaining six have mean heights which successively represent, say, 50lbs., 40lbs., 30lbs., 25lbs., 20lbs., and 15lbs. Now if S = 10ft., each interval being 1ft., we shall have for work done Mean pressure × 10ft.

$$=\frac{(100\times 4)+50+40+30+25+20+15\text{lbs}}{10}\times 10=58\text{lbs}\times 10\text{ft}$$

or the diagram has an area of 580, showing a mean pressure throughout the stroke of $\frac{580\text{lbs.}}{10}=58\text{lbs.}$, and this multiplied by the stroke, which, in our case is 10ft., represents 580 foot pounds. From numerous causes the diagram actually obtained is never square at the corners $d\,e$, and not often at a, but into these causes we shall enter at the proper time.

(TO BE CONTINUED.)

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 431, VOL. XIII.)

Two Coils, with Cores, in Sequence.

From the already obtained solutions in the cases of open and closed coil circuit, we may deduce the solutions in many other cases of interest. Thus any number of similar coils with similar cores, having their cores charged in any manner to begin with, may be joined in sequence, and the resulting phenomena completely determined in terms of two solutions only. We start with a pair of similar coils. Let H_1 and H_2 be the strengths of magnetic force in the first and second core at distances r_1 and r_2 from their axes. When the coils are connected in circuit, the current must be the same in both; hence

$$H_1=H_2=4\pi N\Gamma \quad . \quad . \quad . \quad . \quad . \quad (101)$$

is the continuity condition, the boundary values of H_1 and H_2 being used, whilst Γ is the common coil current.

Let L and R be the coefficient of self-induction and the resistance of the circuit, both complete. The circuit may contain, besides the two coils mentioned, any number of other coils, either without cores, or with cores in which no current is permitted. The self-induction arising from their presence is included in L, so they may be dismissed altogether from consideration, and when we speak of the coils, we refer only to those with cores in which induced currents can flow. Let M be that part of L due to a single core—viz., $M=(2\pi Nc)^2l\mu$ (equation (6) putting M for L_1 for subsequent convenience). Then L − 2M is the coefficient of self-induction not counting the cores, and $-(L-2M)\dot{\Gamma}$ the induced E.M.F. to correspond. Also, the induced E.M.F. arising from the core induction is given by the third term with sign changed of either of equations (19), and is, owing to the coils and cores being alike, of the same form for both cores; so we get, when there is no impressed force in the circuit,

$$0=RH_1+(L-2M)\dot{H}_1+\frac{M\rho}{2\pi\mu c}(H'_1+H'_2),$$

for the equation of E.M.F. in the coil circuit. Or, putting $s=M\rho/2\pi\mu cR$,

$$0=H_1+\frac{L-2M}{R}\dot{H}_1+s(H'_1+H'_2), \quad . \quad . \quad (102)$$

A normal system is of the form

$$h_1=AJ_0(nr_1)e^{Dt}, \qquad h_2=BJ_0(nr_2)e^{Dt};$$

D being the same in both to make h_1 and h_2 subside at the same rate, whilst n is the same in both because the coils are alike. By (101), we therefore have (at the boundaries $r_1=r_2=c$)

$$AJ_0(nc)=BJ_0(nc), \quad . \quad . \quad . \quad . \quad . \quad (103)$$

which gives A = B, provided $J_0(nc)$ does not vanish. Putting the expressions for h_1 and h_2 in (102) we get

$$A\left\{J_0(nc)\left(1+\frac{L-2M}{R}D\right)-snJ_1(nc)\right\}=snBJ_1(nc) \quad (104);$$

and, eliminating A and B from (103) and (104) by cross multiplication, we arrive at the determinantal equation

$$J_0(nc)\left\{\left(1+\frac{L-2M}{R}D\right)J_0(nc)-2snJ_1(nc)\right\}=0 \quad . \quad (105),$$

from which we see that there are two series of roots, viz., those of $J_0(nc)=0$ and those of $\{\ldots\}=0$. These, for distinguishment, we shall call the first and the second set of roots. The first set is the same as we have when the coil circuit is interrupted, and the magnetic energy of the core is converted into heat in the core itself. The second set is the same as we have with a single coil and core, when the coil circuit is closed. (Examples 1 and 3.) With the second set of roots we have A = B, as shown above; with the first set, by using (104), since (103) fails, A = − B. In this last case there is no coil current accompanying the subsidence of the magnetic force normal system. Thus,

$$\left.\begin{aligned}H_1&=\sum_2 AJ_0(nr_1)e^{Dt}+\sum_1 BJ_0(nr_1)e^{Dt}\\ H_2&=\sum_2 AJ_0(nr_2)e^{Dt}-\sum_1 BJ_0(nr_2)e^{Dt}\end{aligned}\right\} \quad . \quad . \quad (106),$$

where the 1 and 2 under the Σ's indicate that the first or the second set of roots is employed.

Hence, by addition and subtraction, using the same value of r in both cases,

$$\tfrac{1}{2}(H_1+H_2)=\sum_2 AJ_0(nr)e^{Dt} \quad . \quad . \quad . \quad (107),$$

$$\tfrac{1}{2}(H_1-H_2)=\sum_1 BJ_0(nr)e^{Dt} \quad . \quad . \quad . \quad (108).$$

The expressions for A and B have been already given, in terms of the initial distributions, so we need not repeat them. Thus (81) gives B, when for H_0 there we write the initial value of $\frac{1}{2}(H_1-H_2)$, and this is a function of r, and (99) gives A, with corresponding alterations to suit the initial value of $\frac{1}{2}(H_1+H_2)$. Thus the theoretical solution is complete.

We may now consider the physical significance of the above, and how to practically apply it. In the first place, suppose the cores are charged to the same strength, and are then joined up so that they *add* their inductive E.M.F.'s in the coil circuit, the impressed forces being removed. Or, more simply, put

Digitized by Google

them in series with a battery, and then remove the latter without breaking the circuit. From symmetry it is evident that the magnetic force subsides in the same manner in both cores, contributing equally to the circuit E.M.F., and that there is a current in the circuit. But as with the first set of roots there can be no coil current, it follows that the second set of roots, with the corresponding normal systems, must be alone in operation.

Next, starting with equal strengths, let the coils be joined so as to produce opposed E.M.F.'s in the coil circuit. These E.M.F.'s being equal, there can be no coil current. The boundary magnetic forces are zero, and the normal systems are those of the first set of roots only, the magnetic force in both cores subsiding in the same manner as if the circuit were interrupted.

Thirdly, let there be initially different strengths of magnetic force in the two cores. Decompose them thus:—

$$\left.\begin{aligned} H_1 &= \tfrac{1}{2}(H_1+H_2)+\tfrac{1}{2}(H_1-H_2) \\ H_2 &= \tfrac{1}{2}(H_1+H_2)-\tfrac{1}{2}(H_1-H_2) \end{aligned}\right\} \quad . \quad . \quad . \quad (109)$$

The portion $\frac{1}{2}(H_1+H_2)$ being the same in both cores, has the second set of normal systems only, thus giving us the solution (107); whilst the portion $\frac{1}{2}(H_1-H_2)$ being opposite in the two cores (as regards the direction of induced E.M.F. in the circuit) produces no current in the circuit, and has therefore the first set of normal systems, thus giving rise to the solution (108). Combining the thus obtained (107) and (108) we obtain the solution for each core by itself, expressed in equations (106).

We have in this deduction of (106) supposed H_1 and H_2 initially constant, but the reasoning plainly holds good when H_1 and H_2 are functions of r_1 and r_2, and are decomposed as in (109) into like and unlike auxiliary systems.

Now we have, in Fig. 3, given the curve of subsidence of magnetic force initially steady at the axis of a core, corresponding to the first set of roots of (105), and also the curves of subsidence at the axis and at the boundary for a particular case of the second set, viz.: coil of small depth, and a certain value of its time constant. Therefore from curves h_0h_0 and H_0H_0 (Fig. 3) (the last being with $2s=1$ in (105), and $a=c$), or a similar curve instead of H_0H_0 when $2s$ is not $=1$, we can draw the curves to suit the present problem. (Fig. 3 is unfortunately not quite so distinct as it might be, owing mainly to its reduction in scale from the original, which was drawn the same size as Fig. 2, to say nothing of the curves having got somewhat out of shape in the reduction. Also, H_2 should be H_a.)

If, at starting, the cores are equally charged, and the coils are joined so as to add the E.M.F.'s, the subsidence of magnetic force takes place similarly in both cores, being represented by H_aH_a at their boundaries (also the subsidence of the coil current) and by H_0H_0 at their axes.

But if they are connected so that the E.M.F.'s are opposed in the circuit, there is no coil current, and the subsidence in the cores is accelerated, being, at their axes, represented by h_0h_0.

Next, let one core only be charged, to begin with, and its coil then connected with the second coil with uncharged core, the battery being removed. The subsidence (axial) in the first core is got by taking the mean of H_0H_0 and h_0h_0 in Fig. 3.; *i.e.*, construct the curve whose ordinate for any value of the time is one half the sum of the ordinates of H_0H_0 and h_0h_0 at the same time. And the curve of magnetic force at the axis of the second core is got by constructing the curve whose ordinate is one half the difference in the ordinates of H_0H_0 and h_0h_0. The resulting curve, starting from zero, shows initial retardation, rises rapidly to a maximum, and falls thereafter slowly to zero again, as a portion of the energy originally in the first core is transmitted into the second, there to subside.

If both cores are charged to start with, but to different strengths, we must construct our curves by taking the ordinates of H_0H_0 and h_0h_0 in the proper proportions shown by the decomposition in (109), adding them for one core, subtracting for the other, to obtain the ordinates of the required curves.

The boundary force and the coil current curves may be got from the curve H_aH_a alone by merely altering its scale vertically, there being no coil current to correspond to h_0h_0. That is, directly the coils are connected, the current alters its strength to suit the mean initial force $\frac{1}{2}(H_1+H_2)$. For example, if the second core is uncharged the current drops suddenly to half strength.

(TO BE CONTINUED.)

CORRESPONDENCE.

BALL'S UNIPOLAR MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. H. A. Kent regarding the Ball Unipolar Dynamo, I noticed particularly the lights produced by the machine referred to. Whilst I had no opportunity of measuring the candle-power of the lights it was evident to the eye that they were much below the usual arc light of 2,000 candle-power. The dynamo was run at an enormously high rate of speed, driven by a very small belt, which travelled rapidly.

I saw no better results than would be produced by an ordinary Gramme machine, run at same speed. By the way, why should this machine be called unipolar? It has two poles and two armatures, one for each armature. It is difficult to see why this machine should be as efficient as a Gramme.—Yours, &c.,

A. KITSON.

125, North Seventh-street, Philadelphia, Pa.,
October 28, 1884.

10-LIGHT VICTORIA DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will any of your readers kindly inform me on the following points connected with the above machine:—

What is the resistance and size of wire wound on armature, and how many sections are there?

Also, resistance and size of wire wound on the field magnets, of which there are two pairs of poles. Please also give resistance and size of shunt wire.

What is the width of the ring armature?—Yours, &c.,

PHONO.

DANGERS TO ELECTRIC LIGHT WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In laying electric light leads under floors in old houses, I have been often afraid that rats or mice would attack the wires, and so cause a short circuit or leak.

To obviate this I have enclosed some of them in zinc tubing, and others I have simply painted over with Stockholm tar, after they were in position, which I believe will prevent rats from attacking them.

Can any of your readers, more particularly Mr. Moseley, who, I believe, has had great experience in this kind of work, tell me if he is aware of any cases of bell or other wires which have been attacked by rats, and if they can recommend any special means to guard against such risks?—Yours, &c.,

A. S. T. E. and E.

PROVISIONAL LICENSES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am anxious to get information relative to the cost of obtaining a license from the Board of Trade under the Electric Lighting Act. I shall therefore be glad if you will let me have the names of any local authorities or companies who have obtained licenses under the above Act.

In my case the license is required by the local authority for the district, so that there will be no opposition to such.—Yours, &c.

OHM.

TELEGRAPHY AND TELEPHONY ON THE MIDLAND.

(FROM OUR OWN CORRESPONDENT.)

The Midland Railway is worked upon the absolute block system; while at the same time an interlocking system, by means of which the electric signals are electrically interlocked with the mechanical signals, is employed experimentally between the Trent and Derby stations on the London and Manchester main line. That is to say, for instance, a man at signal box B is unable to take off his signals so as to allow a train to proceed to A until he has obtained permission from A, or until A has given B the "All clear" signal on his block instrument. The chief merit of this interlocking system, which has been devised by Mr. W. E. Langdon, superintendent of the telegraph department, is its applicability to any existing form of block signals. The final action, which forms the "Train on line," or block signal, locks the instrument in that position; and the locking continues until it is released by the train in passing, or, in case it be desired, until the receipt of the *block* signal for the said train from the section in advance. The action of the signalman is in no way interfered with; but, should he attempt to pull over his signal lever, or to release the electrical block signal, when he ought not to do so, he would find it physically impossible. The contact arrangement in connection with the metals is self-adjustable, so that there is no need for readjustment when the sleepers are freshly packed, nor when the road becomes depressed from an excess of moisture. In either case, the contact adjusts itself to the position of the lever fixed to the rail, provision against submersion from floods being also provided for. With this system it is not possible for the signalman to give the "Clear" signal upon his starting or controlling signal, until he has obtained the "Clear" signal from the next block post towards which the train is about to proceed. Nor is it possible for the signalman to release the "Train on line" or *block* signal on his electrical instrument until the train has passed out of the section; and further, not until he has signalled such train on to the block post in advance, and received therefrom the *block* or "Train on line" signal for such train.

In several places where there are many lines and the traffic is heavy, as at Birmingham, Leeds, Bradford, Derby, and Peterborough, telephone circuits are used to assist the signalmen, and to aid in passing on the traffic, which at these places becomes sometimes rather congested. For instance, suppose a light engine or a train of empties was wanted to proceed from one point to another, between which there were several routes, the signalman would ascertain by telephone by which route the clearest passage was afforded. All telephone circuits have double wires, and when a number of telephone wires are hung together on the poles, each circuit is formed by a double wire.

At Derby, the head-quarters of the railway, is also the central telegraph station, the number of messages through which averages 5,500 a day, and sometimes amounts to 6,000, while the number of messages on the whole Midland system reaches 14,000, and sometimes 17,000, daily. When the traffic is impeded from any cause, the number of messages naturally increases; and this applies not only to the service but also to the private messages, which the Midland Company send on behalf of the Post Office Department. A system, in use on no other railway, has been introduced by Mr. Langdon, of making the receiving instruments give audible signals, so that the operator can write down the message without looking at the instrument; in this way a great saving of time is effected, so that fifty messages an hour can be received by one clerk, or 15 per cent. more than by a good operator with the ordinary needle instrument. The pulse of the telegraph is felt regularly every morning between 7:45 and 8 a.m., by testing all the more important circuits. The telephone is used for reporting, from the signal box to the telegraph office, the starting of trains on principal sections, and also any delay in starting trains on all others. A message is then telegraphed to all the signalmen along the line interested, which knowledge often permits them to send on a mineral train, which would otherwise be kept waiting.

The telegraph works, employing from fifty to sixty men, are very complete, consisting of battery and insulator, mechanics' and joiners' shops, paint and polishing shops, general stores, instrument room, and offices. The whole is lighted by sixty-five 20-candle Swan incandescent lamps, with a few Hammond arc lights, maintained by a Siemens compound-wound shunt dynamo, driven by a 4 horse-power nominal steam engine, which serves, during the day, to work the saws and lathes. The lamps are run in parallel arc, with safety fuzes made of very fine copper wire, the number of lamps depending on that of the lamps protected by the fuse.

ELECTRICAL BELL INDICATOR.

A cheap and simple form of apparatus to indicate that an electric bell is in working order, and that the circuit is in a proper condition, has long been a desideratum in the now almost universal system of bell work, and many attempts have been made to provide an apparatus that would fulfil this want. Mr. J. Kenneth D. Mackenzie has patented an instrument which it is thought will go far to supply this want. We now give some sketches of the apparatus, showing the general design. The principle of the invention is this, that iron when magnetised and demagnetised emits a sound

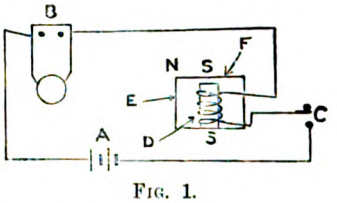

FIG. 1.

Fig. 1 shows the principle of the apparatus, in which A is a battery, B a bell, C an ordinary bell push, D an electro-magnet having one of its poles connected to the base of a small sheet iron box, E, having lid, F, of the same material. The electro-magnet D forms part of the bell circuit, and one of its poles being connected to the base of the box, as described, the lid becomes the polar extension of the magnet D.

When the circuit is joined at C a current flows along the line to the bell B, passing round the electro-magnet D, and back to the battery, and therefore the lid F and magnet D become magnetised and emit a sound. When the bell mechanism

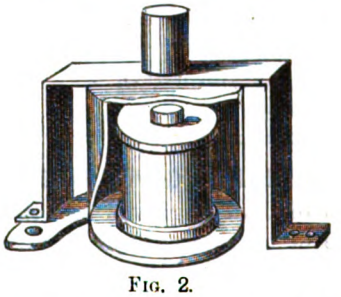

FIG. 2.

interrupts the circuit the magnet D and the lid F lose their magnetism and again emit a sound. This is the well-known so-called "Page effect" made use of practically. In practice the box is made small, not larger than 1in. in diameter, and with the ordinary allowance of battery power gives out a sound capable of being heard quite 20ft. away. The use of such an instrument is obvious, and for telephone circuits between subscriber and exchange, or between exchanges themselves, it will be of great importance, as it shows every time the call bell is run that the bell is actually ringing, and that therefore the circuit is in proper order.

On railways between signal boxes this little indicator would be of great importance, as the pointsman would be certain that the signal transmitted by him to the distant signal box had been received.

Fig. 2 shows the indicator as combined with an ordinary bell push, forming one complete instrument. As the indicator is *audible* it can be used in the dark as well as daylight, and is therefore more generally serviceable than a *visual* one would be.

ELECTRIC LIGHTING FOR STEAMSHIPS.

The Institution of Civil Engineers has this week testified to the importance of the subject to which we adverted in our last week's leading article by devoting the first meeting of its winter session to the consideration of electric lighting applied to steamships. Mr. A. Jamieson's paper, which we hope shortly to be able to print in extenso, was an interesting and encouraging account of much that has already been undertaken in this line of business; and as he himself has been closely associated with the success of many of these installations on board ship no better authority could have been chosen by the Institution to furnish trustworthy information to its members on a subject of fast growing importance.

We say that Mr. Jamieson's paper and the discussion that followed it were encouraging, because the successes attending these efforts to provide a wholesome and agreeable light for passengers travelling by sea will directly tend to promote the extension of similar efforts on land. Electrical engineers like Mr. Jamieson have enjoyed the exceptional advantage of being free from the machinations of the company-mongers, and what is even of greater moment, from the trammels of the Electric Lighting Act. Nothing, perhaps, could better illustrate the superiority of an industry standing on its own merits and pushing its way by force of competitive good management. Contrasted with the condition of the same kind of business handicapped by grandmotherly legislation the progress of maritime electric lighting may be called a complete triumph; and as some of Mr. Chamberlain's handiwork has already received its severest check from the same quarter, we may be permitted to hope that this message from the region of shipping interests will prove equally efficacious in undoing more of what remains.

Mr. Jamieson's statistics of the progress of electric lighting on board steam vessels are a surprise even to us. It is now, apparently, considered an indispensable luxury that every newly built steamer shall be fitted with the new illuminant, and a great number of existing passenger vessels have already introduced it as a welcome improvement. Some idea of the extent to which this business has been carried may be gathered from the fact that one particular firm mentioned in the paper have within the past few years supplied no fewer than 616 engines for driving dynamos, 242 of which are for use on board men-of-war. For passenger steamships this is not the engine most favoured, and perhaps not the one most used, so that we may conclude that if we had complete statistics with regard to the rest, these figures would be considerably swollen. A singular omission we thought we noticed in respect to the supply of electric lighting appliances to vessels of war. France and Italy had taken a great number, especially the former country, and the rest of the navies of Europe and America had also obtained a fair number; but no mention was made of the British navy. The omission proves nothing, and of course we know that the electric light is employed on British ships of war; but it would have been interesting just now to have had fuller information on the subject.

Much useful information gained by practical experience was furnished by Mr. Jamieson as to the best means of leading the wires in iron built vessels, the kind of switches most suited for the peculiar exigencies of a sea voyage, and the most efficient form of safety fuse for guarding against overtaxing the lamps. A sensitive and trustworthy governor for the engine is also an indispensable adjunct at sea, more so than on land; and the lecturer has himself invented an appliance of the kind which to all appearance will answer the purpose admirably. Several other precautions and modifications of systems well adapted for solid earth have to be introduced into the arrangements for installing the electric light where the shifting and rolling caused by a heavy sea are to be guarded against. For full details of the provisions needful we must refer our readers to Mr. Jamieson's paper. But the important fact to be noted is that the difficulties attending such novel conditions have been satisfactorily overcome already, and that fresh installations are being called for every day.

The incandescent system is, of course, the one almost exclusively employed, though for certain purposes even on board passenger ships the arc light may be introduced with advantage. For search lights on men-of-war the latter is the only serviceable instrument; and Mr. Jamieson mentions instances where it has been employed also for fishing and salvage purposes as a submarine illuminator. We may also add that for signalling at sea the arc light, at all events if the steadiness of the carbons is not seriously affected in rough weather, will prove of great value, and we hope that our naval authorities have by this time enlisted it among the recognised methods of maritime telegraphy. But for general uses the incandescent lamp has won the largest, if not exactly the first, place at sea, as it has on land. The superiority of either kinds of lights,

Digitized by Google

however, over oil or candle, for ship use, is obvious. The cleaning and replenishing of lamps is done away with, the danger of storing inflammable oils is avoided, and the temperature of the saloons and cabins is greatly reduced. We are not sure we can concur in Mr. Jamieson's claim for the electric light that the danger from matches and lighted tapers is lessened. This is a danger incurred anywhere and everywhere; and as you cannot light a cigar at an incandescent lamp, matches may be in greater demand among smokers than ever. The danger, however, is not from matches and tapers but from what they come in contact with; and it is a distinct gain in this respect to have got rid of that hoary offender "oil," whose crimes against our stomachs as well as against our safety are now happily past all forgiveness. On the whole, we have to congratulate the electrical world on the cheerful facts disclosed in Mr. Jamieson's paper, and to express our conviction at the commencement of this new volume that, notwithstanding the discouragement with which fortuitous circumstances have surrounded electric lighting, the time is not far distant when success, similar to that recorded of it at sea, will mark its progress in our social and industrial life on shore. Bad as is the account of the year's business of one great company, the report we publish in another column shows that the turning point has been passed, and that the concern can now be worked on profitable lines.

THE THEORY OF ALTERNATING CURRENTS.*

BY J. HOPKINSON, F.R.S.

In my lecture on electric lighting, delivered before the Institution of Civil Engineers last year, I considered the question of two alternate-current dynamo machines connected to the same circuit, but having no rigid mechanical connection between them, and I showed that if two such machines be coupled in series they will tend to nullify each other's effect; if parallel, to add their effects. The subject is one which already has practical importance and application, and may have much more in the future; it is also one suited for discussion, and upon which discussion is desirable. I therefore venture to bring before the society what I said in my lecture, some other ways of looking at the same subject, and an experimental verification, together with solutions of other problems requiring similar treatment.

The general explanation, amounting to proof so far as machines in series are concerned, is given in the following extract from my lecture:—

"There remains one point of great practical interest in connection with alternate-current machines—how will they behave when two or more are coupled together, to aid each other in doing the same work? With galvanic batteries we know very well how to couple them, either in parallel circuit or in series, so that they shall aid, and not oppose, the effects of each other; but with alternate current machines independently driven, it is not quite obvious what the result will be, for the polarity of each machine is constantly changing. Will two machines coupled together run independently of each other, or will one control the movement of the other in such wise that they settle down to conspire to produce the same effect, or will it be into mutual opposition? It is obvious that a great deal turns upon the answer to this question, for in the general distribution of electric light it will be desirable to be able to supply the system of conductors from which the consumers draw by separate machines, which can be thrown in and out at pleasure. Now, I know it is a common impression that alternate-current machines cannot be worked together, and that it is almost a necessity to have one enormous machine to supply all the consumers drawing from one system of conductors. Let us see how the matter stands. Consider two machines independently driven, so as to have approximately the same periodic time and the same electromotive force. If these two machines are to be worked together, they may be connected in one of two ways: they may be in parallel circuit with regard to the external conductor, as shown by the full line in Fig. 6—that is, their currents may be added algebraically and sent to the external circuit; or they may be coupled in series, as shown by the dotted line—that is, the whole current may pass successively through the two machines, and the electromotive force of the two machines may be added, instead of their currents. The latter case is simpler. Let us consider it first. I am going to show that if you couple two such alternate current machines in series, they will so control each other's phase as to nullify each other, and that you will get no effect from them;

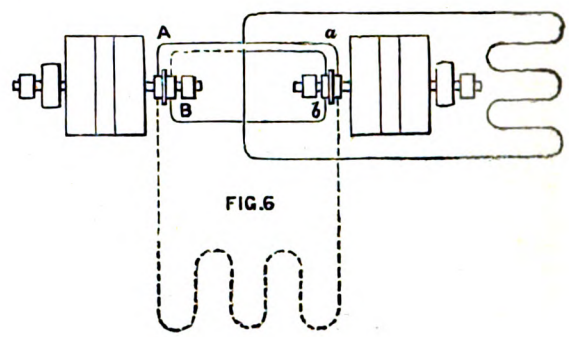

FIG.6

and, as a corollary from that, I am going to show that if you couple them in parallel circuit, they will work perfectly well together, and the currents they produce will be added; in fact, that you cannot drive alternate-current machines tandem, but that you may drive them as a pair, or, indeed, any number abreast. In diagram (Fig. 7) the horizontal line of abscissæ represents the time advancing from left to right; the full curves represent the electromotive forces of the two machines not supposed to be in the same phase. We want to see whether they will tend to get into the same phase or to get into opposite phases. Now, if the machines are coupled in series, the resultant electromotive force on the circuit will be the sum of the electromotive forces of the two machines. This resultant electromotive force is represented by the broken curve III; by what we have already seen in Formula IV., the phase of the current must lag behind the phase of the electromotive force, as is shown in the diagram by curve IV, thus —.—.—. Now, the work done in any machine is represented by the sum of the products of the currents and of

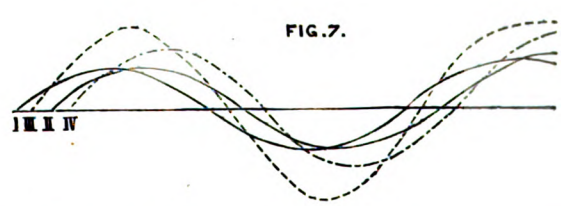

FIG.7.

the electromotive forces, and it is clear that as the phase of the current is more near to the plase of the lagging machine II than to that of the leading machine I, the lagging machine must do more work in producing electricity than the leading machine; consequently its velocity will be retarded, and its retardation will go on until the two machines settle down into exactly opposite phases, when no current will pass. The moral, therefore, is, do not attempt to couple two independently driven alternate-current machines in series. Now for the corollary. A B (Fig. 6) represent the two terminals of an alternate-current machine; *a b* the two terminals of another machine independently driven. A and *a* are connected together, and B and *b*. So regarded, the two machines are in series, and we have just proved that they will exactly oppose each other's effects—that is, when A is positive, *a* will be positive also; when A is negative, *a* is also negative. Now, connecting

* Paper read before the Society of Telegraph Engineers and Electricians on November 13th.

Digitized by Google

A and *a* through the comparatively high resistance of the external circuit with B and *b*, the current passing through that circuit will not much disturb, if at all, the relations of the two machines. Hence, when A is positive, *a* will be positive, and when A is negative *a* will be negative also; precisely the condition required that the two machines may work together to send a current into the external circuit. You may therefore with confidence attempt to run alternate-current machines in parallel circuit for the purpose of producing any external effect. I might easily show that the same applies to a larger number; hence, there is no more difficulty in feeding a system of conductors from a number of alternate-current machines than there is in feeding it from a number of continuous-current machines. A little care only is required that the machine shall be thrown in when it has attained something like its proper velocity. A further corollary is that alternate currents with alternate-current machines as motors may theoretically be used for the transmission of power."*

Although the proof of this corollary regarding motors is similar to what we have just been going through, it may be instructive to give it. In the accompanying diagrams the full lines I and II represent the electromotive forces of the two machines (generator and receiver); the dotted line, curve III (. . . .), the resultant electromotive force; and the curve IV, the resulting current, each in terms of the time, as abscissæ.

FIG. 1.

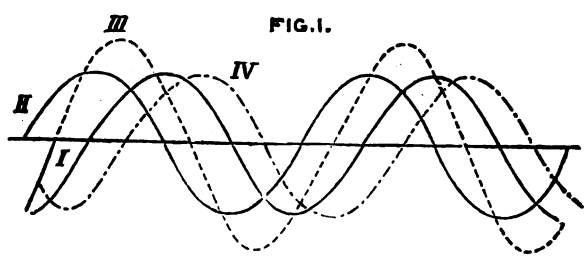

FIG. 2.

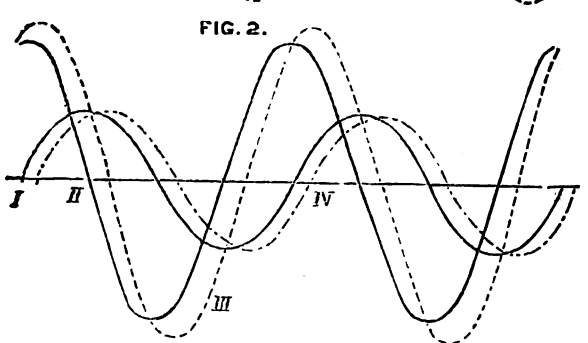


The only difference between the two diagrams is, that in Fig. 1 the two machines have equal electromotive forces, whilst in Fig. 2 *the receiving machine has double the electromotive force of the generator.*

In both figures the receiving machine lags behind the phase of direct opposition to the generator by one-quarter of a period, or something less. Now observe, the resultant electromotive force must be in phase behind the receiver, but in advance of the generator. Also observe, the current must be in phase behind the resultant electromotive force, and may be one-quarter of a period behind, provided only the self-induction be large enough compared with the resistance. The current will then be less than a quarter period behind the generator. This machine will do work upon the current, but the current will be more than a quarter period behind the receiving machine; therefore in the receiver the current does work upon the machine.

The subject is illustrated by the following problems. Of course any of them may be treated more generally by considering the machines as unequal, or by introducing other periodic terms, but I do not see that this would throw more light on the subject:—

I. *Two alternate-current machines, equal in all respects, are connected in series and independently driven at the same speed, to determine the current, &c., in each.*

Let γ be the coefficient of self-induction of each, r the resistance, x the current at time t, and $E \sin \frac{2\pi}{T}(t+\tau)$ and $E \sin \frac{2\mu}{T}(t-\tau)$ the electromotive forces. Then regarding the coefficient of self-induction as constant, which it is not exactly, and neglecting the effect of currents other than those in the copper wire, the equation of motion is

$$2\gamma x' + 2rx = E\left\{\sin.\frac{2\pi}{T}(t+\tau) + \sin.\frac{2\pi}{T}(t-\tau)\right\}$$

or

$$\gamma x' + rx = E \sin.\frac{2\pi t}{T}\cos.\frac{2\pi\tau}{T}$$

whence

$$x = \frac{E\cos.\frac{2\pi\tau}{T}}{r^2+\left(\frac{2\pi\gamma}{T}\right)^2}\left\{r\sin.\frac{2\pi t}{T} - \frac{2\pi\gamma}{T}\cos.\frac{2\pi t}{T}\right\}$$

Work done by the leading machine per second

$$= \frac{E^2\cos.\frac{2\pi\tau}{T}}{2\left\{r^2+\left(\frac{2\pi\gamma}{T}\right)^2\right\}} \cdot \left\{r\cos.\frac{2\pi\tau}{T} - \frac{2\pi\gamma}{T}\sin.\frac{2\pi\tau}{T}\right\}$$

$$= \frac{E^2}{4\left\{r^2+\left(\frac{2\pi\gamma}{T}\right)^2\right\}} \cdot \left\{r\left(1+\cos.\frac{4\pi\tau}{T}\right) - \frac{2\pi\gamma}{T}\sin.\frac{4\pi\tau}{T}\right\}$$

From this at once follows that the leading machine does least work, and will tend to increase its lead until $\tau = \frac{T}{4}$, when the two machines will neutralise each other, as already proved geometrically. *The leading machine may actually become a motor and do mechanical work, although its electromotive force is precisely equal to that of the following machine.*

Considering the important case when r is negligible, we have

$$x = -\frac{E\cos.\frac{2\pi\tau}{T}\cdot\cos.\frac{2\pi t}{T}}{\frac{2\pi\gamma}{T}}$$

$$\text{rate of working} = \frac{E^2\sin.\frac{4\pi\tau}{T}}{4\cdot\frac{2\pi\gamma}{T}}.$$

This is a maximum when $\tau = \frac{T}{8}$, and then it is equal to one-half of the maximum work which can be obtained from either machine when connected to a resistance only, which occurs when that resistance is $\frac{2\pi\gamma}{T}$; the current, however, is the same as when the maximum work is being done on resistance, and is $\frac{1}{\sqrt{2}}$ of the current the machine will give if short-circuited. The difference of potential between the two leads connecting the machines, whether $r=0$ or not, is $E\cos.\frac{2\pi t}{T}\sin.\frac{2\pi\tau}{T}$. If there be no work done on the receiving machine and $r=0$, $\tau=\frac{T}{4}$, and the amplitude of the difference of potential between the leads is E; if, on the other hand, the maximum work is being transmitted, the potential measured will be $\frac{1}{\sqrt{2}}$ of that observed when either machine is run on open circuit.

* "Of course, in applying these conclusions, it is necessary to remember that the machines only *tend* to control each other, and that the control of the motive power may be predominant, and *compel* the two or more machines to run at different speeds."

Digitized by Google

II. *Two machines are coupled parallel and connected to an external circuit resistance* R.

Let $x_1 x_2$ be currents in the two machines. The external current will be $x_1 + x_2$, and consequently the difference of potential at the junction, R $(x_1 + x_2)$.

Let the electromotive forces of the two machines regarded in this case as connected parallel be E sin. $\frac{2\pi(t \pm \tau)}{T}$ and let the self-induction and resistance of each be $e\gamma$ and $2r$.

The equations of motion then are

$$2\gamma x'_1 + 2r x_1 = \text{E sin.} \frac{2\pi(t+\tau)}{T} - \text{R}(x_1 + x_2)$$

$$2\gamma x'_2 + 2r x_2 = \text{E sin.} \frac{2\pi(t-\tau)}{T} - \text{R}(x_1 + x_2)$$

whence

$$\gamma(x'_1 + x'_2) + (\text{R} + r)(x_1 + x_2) = \text{E sin.} \frac{2\pi t}{T} \cdot \text{cos.} \frac{2\pi\tau}{T}$$

and

$$\gamma(x'_1 - x'_2) + r(x_1 - x_2) = \text{E cos.} \frac{2\pi t}{T} \text{ sin.} \frac{2\pi\tau}{T}$$

Solving these,

$$x_1 + x_2 = \frac{\text{E cos.} \frac{2\pi\tau}{T}}{(r+\text{R})_2 + \left(\frac{2\pi\gamma}{T}\right)^2} \left\{ (r+\text{R}) \text{ sin.} \frac{2\pi t}{T} - \frac{2\pi\gamma}{T} \text{ cos.} \frac{2\pi t}{T} \right\}$$

$$x_1 - x_2 = \frac{\text{E sin.} \frac{2\pi\tau}{T}}{r^2 + \left(\frac{2\pi\gamma}{T}\right)^2} \left\{ r \text{ cos.} \frac{2\pi t}{T} + \frac{2\pi\gamma}{T} \text{ sin.} \frac{2\pi t}{T} \right\}$$

electrical work done by the leading machine

$$= \tfrac{1}{2}\text{E sin.} \frac{2\pi(t+\tau)}{T} \left\{ x_1 + x_2 + (x_1 - x_2) \right\}$$

$$= \tfrac{1}{4} \frac{\text{E}^2}{(r+\text{R})^2 + \left(\frac{2\pi\gamma}{T}\right)^2} \left\{ (r+\text{R}) \text{ cos.}^2 \frac{2\pi\tau}{T} - \frac{2\pi\gamma}{T} \text{ sin.} \frac{2\pi\tau}{T} \text{ cos.} \frac{2\pi\tau}{T} \right\}$$

$$+ \tfrac{1}{4} \frac{\text{E}^2}{r^2 + \left(\frac{2\pi\gamma}{T}\right)^2} \left\{ r \text{ sin.}^2 \frac{2\pi\tau}{T} + \frac{2\pi\gamma}{T} \text{ sin.} \frac{2\pi\tau}{T} \text{ cos.} \frac{2\pi\tau}{T} \right\}$$

This expression shows that *the leading machine does most work in all cases.* Suppose r is small compared with R and $\frac{2\pi\gamma}{T}$, also that $\text{R} = \frac{2\pi\gamma}{T}$, we have the work done per second

$$= \frac{\text{E}^2}{8\text{R}} \left\{ \text{cos.}^2 \frac{2\pi\tau}{T} + \text{sin.} \frac{2\pi\tau}{T} \text{ cos.} \frac{2\pi\tau}{T} \right\}$$

make $\tau = -\frac{T}{8}$, and we see that the following machine will then do no work; when τ exceeds this, the following machine becomes a motor and absorbs electrical work.

(TO BE CONTINUED.)

MAGNESIUM BY ELECTROLYSIS.—Works have been put up at Charlottenburg, in Prussia, with a 100 horse-power engine driving four dynamos, for producing pure magnesium at a cheap rate by electro deposit. What has been accomplished leads to the hope that about 3cwt. of magnesium may be produced daily, at a cost not exceeding 10s. a pound.

ON THE INFLUENCE OF CENTRIFUGAL FORCE ON HIGH SPEED BELTING.

BY GISBERT KAPP.

The problem of getting a maximum of power and speed into a machine by means of belting is of considerable interest to the makers and users of dynamos. In comparison to its size a modern dynamo is an excellent apparatus for consuming power, and since its electrical output and commercial value both increase with the speed, it is advantageous to run it as fast as is mechanically possible or safe. In most cases the power is transmitted to the dynamo by a belt, the size of which ought to be determined not only with regard to the useful work done, but also with regard to strains due to its own weight. In ordinary belt or rope gear the latter may be neglected, because the speeds are so low that any small additional strain due to centrifugal force is amply covered by the usual margin of safety. Hence, the rules and tables generally found in hand books are deduced under the supposition that the belt has no weight. Another supposition is also made, viz., that the belt be perfectly flexible. In reality this is not the case; there is always some stiffness in the belt, which causes the side running towards the pulley to stand at a greater distance from the axle than the side running from the pulley. The difference in leverage between the two sides causes a certain loss of power, which is, however, very trifling with old belts put on moderately tight.

Of much greater importance is the effect of centrifugal force on high speed belting. Each portion of the belt as it comes round the pulley is subjected, by reason of its temporary circular motion, to a certain amount of centrifugal force, which tends to lift it off the face of the pulley. Whether separation does actually take place depends on the proportion between this force and the tension in the belt; but even if the belt is not completely lifted off the pulley there is a tendency to diminish its grip on it. Hence less power will be transmitted than corresponds theoretically to the strain in the belt. To counteract the influence of centrifugal force, it is therefore necessary to tighten the belt beyond what would suffice for the transmission of the power by means of a weightless belt, and thus an additional strain is put on to the belt, which in some cases may become so great that most of its tensile resistance is monopolised by it, leaving only a small margin for the transmission of the power. Under these circumstances the effect of centrifugal force must be taken into account, so that the total strain in the belt may be known; but this alone is not sufficient. Having determined the extent of an evil, we naturally inquire whether there be no remedy to lessen it, *i.e*, we desire to know how to design belts and pulleys so that the total strain shall be a minimum for each given case.

That a condition of minimum tension in the belt must always be possible will be evident from the following simple consideration:—

Imagine we have a dynamo which must be supplied with a certain amount of mechanical energy at a fixed number of revolutions. The width and thickness of the driving belt shall also be given, but the diameter of the pulley shall be left to the judgment of the engineer. If he chooses a pulley of small diameter, the strain in the belt due to the energy transmitted will be considerable, but that due to centrifugal force will be small. As he increases the diameter of the pulley he will lessen the former but augment the latter strain, and since the total strain is the sum of these two, it is reasonable to expect that there exists one definite diameter of pulley for which that sum becomes a minimum. It will be shown presently that this minimum is attained when the strain due to centrifugal force is exactly half that due to useful work transmitted.

Let in the annexed sketch—

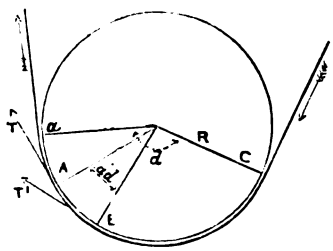
R be the radius of the pulley in feet.
A B an infinitely small portion of the belt measured along the circumference.
$d\alpha$ the corresponding angle.
γ the weight of one foot of belting in pounds.
T and T_1 the strains in the belt at A and B respectively.

Digitized by Google

Suppose that the pulley is being driven by the belt, and that the movement takes place as indicated by the arrows; the greatest tension will then be in A and the least in B, whilst intermediate points of the belt will be strained less than A, and more than B, the strain in fact diminishing in some well-defined manner from A to B. The difference of strain in these two points equals the tangential driving force, and the difference of strain between any two intermediate points gives us that part of the driving force which is due to the corresponding portion of the belt. Thus the driving force exerted by the portion A B is

$$d\,T = T - T_1.$$

This force is transmitted to the face of the pulley by friction. Let ϕ be the coefficient of friction, then by multiplying the



pressure between pulley and belt by ϕ we obtain the force transmitted. If the belt had no weight the pressure exerted by the piece A B against the face of the pulley would evidently be

$$T \sin.\frac{d\,\alpha}{2} + T_1 \sin.\frac{d\,\alpha}{2},$$

or, since $d\,\alpha$ is an infinitely small angle and the difference between T and T_1 is also infinitely small,

$$T\,d\,\alpha.$$

But this pressure is partly taken off by the centrifugal force of the piece A B, the weight of which is

$$\gamma\,R\,d\,\alpha.$$

This weight revolving at the radius R n times a minute round the shaft produces a centrifugal force equal to

$$\cdot 000344\ \gamma\,R\,d\,\alpha\,R\,n^2,$$

or, if for simplicity we write ϵ instead of ·000344, the centrifugal force due to the infinitely small piece of belting A B is

$$\epsilon\,\gamma\,R^2\,n^2\,d\,\alpha.$$

This deducted from $T\,d\,\alpha$ and multiplied with ϕ gives the driving force of A B

$$d\,T = \phi\,(T - \epsilon\,\gamma\,R^2\,n^2)\,d\,\alpha;$$

which integrated between the limits $\alpha = o$ and $\alpha = \alpha$ gives the total tangential force transmitted to the pulley.

The term $\epsilon\,\gamma\,R^2\,n^2$ has a definite meaning; it is the centrifugal force which would be exerted by a piece of belt as long as the radius of the pulley, if the weight of this piece were concentrated in one point on the face of the pulley.

Write for brevity $\epsilon\,\gamma R^2\,n^2 = \beta$, then by integrating

$$d\,T = \phi\,(T - \beta)\,d\,\alpha$$

we obtain

$$\int \frac{d\,T}{T-\beta} = \phi\,\alpha$$

$$\text{log nat.}\left(\frac{T-\beta}{t-\beta}\right) = \phi\,\alpha$$

where α is the arc spanned by the belt, T and t the tensions on the tight and slack sides respectively.

It should be noted that the angle α is not to be introduced in degrees, but as the proportion which the arc spanned bears to the radius. For instance, if the belt spans half the pulley $\alpha = 3{\cdot}14$, if it spans one-third $\alpha = 2{\cdot}09$. Should the angle be given in degrees in the first instance the corresponding value of α is

$$\alpha = \text{degrees}\ \frac{6{\cdot}28}{360}.$$

Call F the circumferential force transmitted to the pulley, then we have

$$F = T - t,$$

and by a simple transformation of the above equation for $\phi\,\alpha$, we find the total strain in the tight side of the belt

$$T = \beta + F\,\frac{e^{\alpha\phi}}{e^{\alpha\phi} - 1}$$

where $e = 2{\cdot}718$. . . .

Every student of mechanics is familiar with the equation giving the strain in the driving side of a belt, if its weight can be neglected. This equation is

$$T_0 = F\,\frac{e^{\alpha\phi}}{e^{\alpha\phi} - 1}$$

and it stands in a most simple relation to the formula just found for a belt the weight of which must not be neglected.

$$T = T_0 + \beta$$

Hence the rule: *To find the strain on the driving side of a belt which runs at a high speed, calculate it first in the usual way by neglecting the weight of the belt, and then add to the force thus obtained the centrifugal force which would be exerted by a piece of belt as long as the radius of the pulley if the weight of this piece were concentrated in one point on the face of the pulley.*

Now comes the question whether it is worth while to make this calculation—that is to say, whether the influence of centrifugal force is so serious a matter after all. This can best be seen by an example. Say 20 horse-power has to be transmitted by a 6in. belt ¼in. thick on to an 8in. pulley running at 2,000 revolutions a minute, and say the belt spans 0·4 of the circumference. In this case F = 157·5lbs. In order to find T_0, it would be necessary to calculate the expression $\frac{e^{\alpha\phi}}{e^{\alpha\phi}-1}$, assuming a certain coefficient of friction, ϕ, and knowing the arc spanned.

This calculation can, however, be avoided by the use of tables which are found in every hand-book on the subject. Thus we find that for straps in ordinary working condition spanning 0·4 of the circumference the value given for the expression is

$$\frac{e^{\alpha\phi}}{e^{\alpha\phi}-1} = 1{\cdot}98$$

therefore $T_0 = 1{\cdot}98\,F$, that is $T_0 = 312$lb.

The weight of 4in. of this belting can be taken as 0·24lb. The corresponding centrifugal force is $\beta = 110$lb., consequently the total strain is

$$T = 312 + 110 = 422\text{lb.},$$

being at the rate of 281lb. per square inch of cross section. If it were desired to run the same pulley at 2,500 revolutions per minute, the centrifugal force would become

$$\beta = 172\text{lb.}$$

If the total strain should not be augmented through this increase of centrifugal force, we must make a corresponding reduction in the original strain T_0. That gives

$$T_0 = 250\text{lb. and } F = 126\text{lb.}$$

The corresponding horse-power at 2,500 revolutions is 20; that is, the same as before.

Although we cause the pulley to run 500 revolutions faster than in the former case, yet there is for the same strain in the belt no increase of horse-power obtained. If we drive the same pulley at 3,000 revolutions we have

$$\beta = 247\text{lb.} \qquad T_0 = 175\text{lb.} \qquad F = 98{\cdot}5\text{lb.},$$

and the horse-power transmitted only 18·8, *being actually less than at the lower speed.*

Take for another example the case of a wire rope driving a 4ft. sheave at 600 revolutions per minute.

Assume the rope to be one inch in circumference, and required to transmit 30 horse-power. What will be the maximum strain in it?

The circumferential resistance corresponding to the power required is F = 131·5lb.

The expression $\frac{e^{\alpha\phi}}{e^{\alpha\phi}-1}$ is for wire-rope gear, where the arc spanned by the rope is always equal to half the circumference, equal to 2; we have therefore $T_0 = 263$lbs.

Digitized by Google

One foot of 1in. rope weighs 0·166lb., and the centrifugal force exerted by a piece of rope 2ft. long is

$$c = 80\text{lb.}$$

The total strain is therefore

$$T = 263 + 80 = 343\text{lb.}$$

If there were no centrifugal force, a strain of 350lb. in the rope would suffice to transmit 40 horse-power, whilst through the action of centrifugal force the same strain will only transmit 30 horse-power.

These examples will show that it is sometimes necessary to take the centrifugal force into account when designing high-speed belting, and then the question arises, what diameter of pulley will give the least total strain?

The circumferential force corresponding to horse-power is

$$F = \frac{\eta\,\text{H.P.}}{n\,R},$$

where we write for brevity η instead of 5,250, which coefficient gives F in pounds if the radius be given in feet.

Put $$\kappa = \frac{e^{a\phi}}{e^{a\phi} - 1},$$

then we have

$$\kappa F = T_0$$

and $$T = \kappa \frac{\eta\,\text{H.P.}}{n\,R} + \epsilon\gamma R^2 n^2$$

By forming $\frac{d\,T}{d\,R} = 0$ we find the condition for a minimum strain

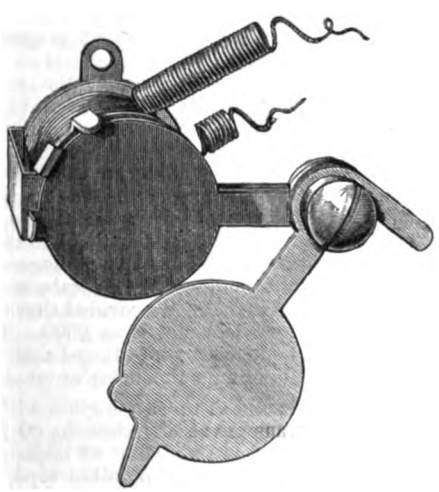
$$R = \frac{1}{n}\left(\frac{\kappa\eta\,\text{H.P.}}{2\epsilon\gamma}\right)^{\frac{1}{3}}$$

If the pulley has this radius the belt will be subjected to the least possible tension; if the pulley be smaller the belt will be strained more on account of the work transmitted; and if the pulley be larger the belt will also be subjected to a greater strain, but this will be principally due to an excess of centrifugal force.

(TO BE CONTINUED.)

THORPE'S SEMAPHORE INDICATOR.

This new electrical indicator has only one moving part; and all the parts are of metal, made by special machinery, and



interchangeable. While taking up but little space, it shows a large aperture, as will be seen by the annexed woodcut. The armature is under the semaphore arm, which immediately drops upon the current passing, thus showing the number, or the name of the room from which the call has been sent; these are then reset by a small bar, with pins, against which the semaphore drops. These instruments are sensitive in action and will work well with a chattering bell in the circuit; they are made for stock in all sizes up to 24 holes. The fronts are made in black mounts, with gilt edges, and with a plain glass in front, so that in case of breakage there is little to replace.

LIGHT FROM INCANDESCENT LAMPS.*

BY W. H. PREECE, F.R.S.

In a paper read before the Royal Society in 1883, I pointed out from experimental data that the light emitted by a glow lamp varied apparently as the sixth power of the current.

I have verified this law, not only by subsequent experiments of my own, but, which is much more satisfactory, by experiments of others. Professor Kittler, of Darmstadt, and Captain Abney have made, independently of each other, most careful and exhaustive measurements in this direction. I have tabulated and traced them out in curves, which I submit. They fully confirm the law that

$$L = k\,C^6,$$

but within limits, and that these limits embrace the ordinary range of a glow lamp when used for artificial illumination. As long as the resistance and the current vary uniformly together the law holds good; but as the state of incandescence is increased, a point is reached, varying with each kind of lamp, when the resistance ceases to diminish at the same rate, and eventually to increase. When this occurs the law is departed from, and the light emitted increases much faster than the sixth power of the current. The filament speedily breaks. The point of departure from the law indicates a point when a change of state occurs in the carbon filament. Disintegration probably sets in. This point ought to be determined for each kind of lamp, and it should never be allowed to be reached, for it is from this point that decay commences and rupture follows.

PROFESSOR JAMIESON ON SHIP LIGHTING.

At the first meeting of the session of the Institution of Civil Engineers, held on the 11th November, Sir J. W. Bazalgette, C.B., President, in the chair, the paper read was on "Electric Lighting for Steamships," by Andrew Jamieson, Assoc. M.I.C.E., F.R.S.E.

The author commenced with the statement that, although it was not more than three years since the first application of incandescent electric lighting to the general illumination of steamships, the advantages accruing therefrom had been so universally recognised, that more than one hundred and fifty ships had been fitted with it, and scarcely a man-of-war or a first-class passenger steamer now left the builder's hands without having it on board. This rapid success was mainly due to the following causes:—(1). Electric lighting on the incandescent system, when properly fitted, was more healthful, cooler, more easily handled, and more artistic than other systems of lighting; there was no smell, and no products of combustion to tarnish giltwork; it was more agreeable in every way than any of the older methods of illumination. (2). The danger from fire was less, as neither matches nor lighted tapers were required. (3). The daily cleaning and replenishing of lamps, as well as the keeping in store of highly inflammable oil, paraffin, or candles, could to a greater extent be dispensed with. (4). The expense of maintenance was not much in excess of that of the older methods of illumination (in some cases less), whilst the space occupied by the plant was not great, and its position near to, or in, the engine room caused no annoyance to passengers.

As the dynamo which furnished the electricity for feeding the incandescent lamps had to be driven at a uniform velocity, neither the ship's main engines, nor the donkey nor winch engines, were suitable for the purpose. The dynamo must have an engine for itself. It was, in most cases, necessary to place this special engine and the dynamo in such a position that the men on watch at the main engines could, with a minimum of trouble, also attend to the electric plant. This position, therefore, was naturally somewhere near the starting platform, and if possible on the ship's floors, so that undue vibration and noise might be avoided. Frequently a convenient recess could be provided, either immediately behind the main starting platform or opposite to the thrust block, just outside the screw-shaft tunnel door. Only in large installations would it pay to have on board an electrician solely to attend to the dynamo, its engine, and lamps. In such cases, a convenient and cool position was generally selected between decks, in the same compartment with, or in that next to, the refrigerating machinery, if such should be on board, so that one man might attend to both of these novel appliances.

Where practicable the axes of dynamos with large, heavy arma-

* A Paper read at the British Association at Montreal.

Digitized by Google

tures should be placed fore and aft, to obviate as much as possible the effects of gyrostatic action, since the angular velocity due to rolling was greatest athwartship. The author here gave Sir William Thomson's formula and examples, to show the pressure produced on the dynamo bearings, under different circumstances, by gyrostatic action.

In selecting a dynamo it was necessary to determine whether or not it fulfilled certain requirements :—(1). It must develop electromotive force suitable for a certain lamp when driven at a certain definite speed. (2). It must be self-regulating ; that was, the electromotive force generated at the given speed must remain constant to within 5 per cent., whether working one lamp or more, or the full number of lamps. It was preferable to have a slight fall in electromotive force as the number of lamps was reduced. (3). There must be no undue emission of sparks at the commutator brushes. (4). When running light, or with less than the full number of lamps, there must be no undue heating of any of the parts. (5). The conductivity of the copper wire with which it was wound must not be less than 96 per cent. of pure copper. (6). The insulation-resistance of the armature and electromagnets should not be less than 10,000 ohms per volt generated at the required speed. The dynamo should be tested mechanically and electrically before being put on board ship, and afterwards, when fixed in position, by a final trial of not less than six hours' duration, with its own engine, and with all the lamps in circuit. There was considerable diversity of opinion regarding the limit of speed of a dynamo on board ship. As a consequence of the general desire for low speeds, most of the best forms of dynamos, the Siemens, the Edison, the Edison-Hopkinson, the Victoria, the Ferranti-Thomson, and the Pilsen-Schukert, had been specially modified for ship use, so as to produce the required electromotive force and current, at speeds varying from four hundred to six hundred and fifty revolutions per minute.

The success or failure of an installation on board ship depended as much upon the engine as upon the dynamo, and every care should be taken to procure one that needed the minimum of attention, and was not likely to break down. The engine should be capable of driving the dynamo during a voyage to Australia and back without a hitch and without requiring overhauling. The demand for such engines, more especially for those driving direct, had led to the production of a great variety, many of them excellent in workmanship and in detail. It was frequently necessary that the engine should be capable of doing its work when supplied with steam either from the main or from the donkey-boilers, so that the electric light might be available in port as well as at sea. This entailed capability for working under variable pressures, and thus the size of the engine must be adapted for the lower pressure. One of the most important adjuncts to the engine was its governor. It should be sufficiently sensitive and reliable in action to keep the engine within 5 per cent. of its normal speed, with a load varying 90 per cent., and a boiler pressure varying 10lb. per square inch. No mechanical governor could do this, and consequently a good electrical governor, which would automatically open and close the throttle-valve, in perfect synchronism with the load, or work to be done, and leave the valve in its last position until a change was made either in the load or in the steam-pressure, was greatly to be desired. The author showed how this problem had been solved by means of his electrical governor.

Then were detailed the different methods of driving dynamos on board ship by belts, ropes, gearing, direct-driving fast-speed engines, such as Brotherhood's, the Westinghouse, Messrs. Siemens' Frictional Drive, &c. The author explained the methods of fitting leading wires into vessels, instancing certain well-known cases by plans of the ss. "Adelaide" and the ss. "Arawa" ; and gave a practical rule which he had been in the habit of using for the dimensions of such wires. Insulation-resistance was too often neglected by electric light engineers. Amongst submarine telegraph engineers it was considered of vital importance to watch the insulation resistance with the most rigid accuracy, not only during the manufacture of a cable, but during its submersion and after it had been laid ; whereas, in the case of electric lighting, those charged with the fitting up of an installation very seldom thought of, or even knew how to take, insulation tests, either of the dynamo or of the leading wires. It was far from right to allow leads to be run up like bell-wires, without the slightest knowledge as to whether a flaw or a fault had crept in, and all engineers should insist upon rigid inspection, as well as thorough and searching tests, before an installation was passed. The insulation resistance standard need not be nearly so high as in the case of submarine cables; but nevertheless it did require to be several hundred times more than the copper resistance, otherwise a fault would soon develop, and short circuiting occur, under the combined influences of the electromotive force, and damp or wet. The dielectric should, therefore, in addition to being a good insulator, be thoroughly water-tight, and as little liable as possible to be affected by atmospheric changes. The author then gave a description of what he had found to be the best form of switches, fusible plugs, lamp-holders, lanterns, and globes. Finally he directed attention to the powerful search-lights used on board men-of-war, and to the novel application of arc lighting for salvage and fishing purposes.

The paper was illustrated by a large number of diagrams.

The announcement for the next meeting was as follows :—

Tuesday, November 18th, at 8 p.m. CIVIL ENGINEERS—Ordinary Meeting.—"Discussion on Electric Lighting for Steamships."

THE METROPOLITAN ASYLUMS BOARD.

[This is, we believe, the *first* specification for electric lighting open to public tender, and, if for no other reason, is historic ; but Dr. Hopkinson has probably herein laid the foundation for all future work of the kind.—ED. *E.*]

Specification for Lighting Machinery for Hospital Ships.

The contract is to include the furnishing, erection and running for a week of regular work of all that is required for the efficient lighting of the three hospital ships—"Atlas," "Endymion," and "Castalia," now moored in the River Thames at Long Reach, the buildings on shore, the pier, and the new road as far as Marsh-road, leading to Dartford. The tenders are to be in accordance with the following specification, but if any contractor desires to propose modifications of the specification for the purpose of employing types of machinery or patterns already in existence such modified tender will be considered. During its progress the work will be from time to time examined by the engineer appointed by the Board or by his representative, but such examination shall not in any way exonerate the contractor from the obligation to remedy any defects which may be found to exist when the machinery is put to work. All workmen employed by the contractor, whether on the ships or at the houses or buildings on shore, must be revaccinated, whether there are at the time patients on board the ships or not. The whole of the work must be completed before 31st January, 1885, unless further time is sanctioned in writing by the engineer or clerk of the Board, and the machinery must be run in regular work for a week by a representative of the contractor without developing any defect, during which time the engineer to the Board may make whatever tests he considers necessary. During this time the Board will provide ordinary labour and coals. In the event of the work not being completed in the time specified and run as above provided to the entire satisfaction of the engineer, the Board shall be at liberty without notice to call in any other person or persons to complete the work and may use all the materials and plant provided by the contractor, and may deduct the expense of doing so from the contract price agreed upon without prejudice to their other rights under their contract.

The managers will pay to the contractor as the works proceed such sums on account of the works as shall be stated in certificates in writing signed by the engineer within one month of the production by the contractor of the said certificates, such certificates to be given at the engineer's discretion at the rate of £75 per cent. on the contract value of the works done and fixed in position upon the said buildings up to the dates of such certificates, and the remainder, or such other sum as may be found due to the contractor on account of the works will be paid by the managers within one month after the date of the engineer's certificate that the works have been completed to his satisfaction, provided that no certificate on account shall be given for a less sum than £500. The decision of the engineer to be employed by the Board shall in all things relating to the contract be binding and conclusive on all parties.

Engines, &c.—To provide and fit up two engines with locomotive boilers, each capable when pressed of indicating 60 horse-power, but to work economically when indicating 40 horse-power. The engines and boilers to be of the semi-portable type, the engines compound condensing, with steam jacketed cylinder, automatic expansion gear, and a thoroughly efficient governor, air pump, condenser, feed pump or injector, and all necessary water pipes and chimney pipes for each engine, and the usual tools for working the engines to be included. The engines and dynamos are to be placed in an engine house provided, behind the present laundries, by the Metropolitan Asylums Board, who will also provide foundations, chimney stack, and flooring. If any contractor tendering prefer to employ other boilers than locomotive boilers, he may submit as an alternative one double-flued Lancashire boiler and one condensing compound engine capable of indicating 70 horse-power and of working economically when indicating 40 horse-power. In this case his tender must be accompanied by a particular speci-

Digitized by Google

fication and drawings of the engine and boiler he proposes to use, and must include the flooring of the engine and boiler house with chequered iron plates, the foundations, and the flues and dampers from the boilers to the chimney stack.

Dynamos.—Two dynamos, compound wound for constant potential of 100 volts, to be supplied, driven respectively by link bands, supplied by the contractor, directly from the fly-wheel of each engine. Each dynamo to be capable of generating in continuous work 250 amperes without excessive heating of any part, and without undue sparking on the commutator. The dynamos must generate the above named current of 250 amperes at 100 volts from power applied by the strap not exceeding 44 horse-power. One spare armature fitting either dynamo, and three sets of spare brushes to be provided. The dynamos are to be carried on rails, provided and fitted by the contractor, and to be fitted with screw tightening gear, so that the belts may be tightened while the dynamos are running.

Lamps.—The lamps to be of 20 and 40 candle-power at 100 volts, and to require respectively not more than 0·62 and 1·24 ampere, and the contractor to guarantee an average life with fair usage of not less than 1,000 hours. The tender to include the supply and placing of 318 lamps of 20 candle-power and 26 of 40 candle-power, but more must be supplied, with their fittings, and connected if required, in accordance with a schedule of prices. Of the 318 20-candle lamps 287 are to be upon the ships and 31 on shore. Of the 26 40-candle lamps 9 are to in three lanterns as masthead lights, 11 on the pier, and 6 on the new road.

Fittings.—Each of the 344 lamps is to have a suitable plain brass bracket or other fitting. Lamp posts are to be provided for the lighting of the pier and new road, all subject to the approval of the engineer. Each of the three groups of masthead lights to be controlled by a single switch. In the stokehole of the "Atlas" there will be two lights on one switch, three lights on bridge from "Endymion" to "Castalia" on one switch, eight lights in each of the holds of the "Castalia" on one switch, entry port of "Castalia" two on one switch. On the pier nine lights are to be on one switch in the engine house and two on another switch in the engine house. In the mortuary on shore two lights on one switch, in the stable four lights on one switch. The six lights in the road to be on one switch in engine house, otherwise every lamp is to have a separate switch. Further a switch is to be provided for controlling together 120 of the cabin lights on the "Endymion," also switches or plugs for detaching at each end each of the four submarine cables, in case of accident, and switch or plugs for connecting either dynamo to the cables. Of the 20-candle lamps sixteen are to be provided with resistances which shall, when thrown into circuit, reduce the light from 20 candles to between 3 and 7 candles. The lamps are all to be placed as shall be indicated by the engineer in consultation by the medical officers of the ships.

Cables and Conductors.—The cables from the engine house to the ships are to be duplicated—that is, four in number—and laid some distance apart for security. The sectional area of copper in each shall not be less than 0·2 square inch. The conductivity of the copper not to be less than 96 per cent. of pure copper. The insulation to be gutta percha, jute yarn, and taped, and the cables to be protected by an iron sheathing. The tenders must contain a complete and detailed specification of cable proposed to be used. In ordinary work all four cables will be used, but a single cable will carry the whole current if accident should occur. For the purpose of this tender the length of each cable is to be taken as 200 yards, but if more or less is required allowance is to be made according to the appended schedule of prices. Both the positive and negative conductors are to be well insulated throughout, and the copper is not to be less than 96 per cent. the conductivity of pure copper. Suitable safety fuses or other cut-outs to be provided, so that the system of conductors exclusive of the cables shall conform to the following conditions when either pair of cables is in use and all the lights lighted. The current in no conductor when carrying its maximum normal load may exceed 1,000 amperes per square inch of section. If the current in any conductor shall exceed 2,000 amperes per square inch of section, such conductor shall be automatically cut out, whether such excess arise from an earth or a "short circuit." No cut-out shall give way with less than 20 per cent above its normal load. During the week's trial run the insulation of the negative or positive part of the whole system, including the cables, shall never be less than 10,000 ohms when running, and when the lamps are all detached the resistance between the two systems of conductors shall not be less than 10,000 ohms. The conductors are to be placed as far as possible out of reach, and not exposed to damp more than is absolutely necessary; on board the ships and in the buildings they are also to be covered with wooden battens, excepting in the case of the masthead lights.

Galvanometers.—Two galvanometers or equivalent instruments to be supplied by the contractor, one to measure the current of 250 amperes, the other a potential of 100 volts. Also suitable means for placing the current galvanometer in the circuit of either dynamo without stopping or breaking its circuit.

Fitting up at Long Reach.—The contractor shall put up the whole of the above described machinery and material and complete the same, so that every part shall be in a state to do its work in a satisfactory manner, finding all necessary material and labour, whether such necessary material and labour is particularly mentioned in this specification or not. He shall also put up any extra lamps, fittings, or wires, as may be required, within one month of the machinery being taken over, at the prices which he shall insert in the following schedule.

Schedule for Extras.

40-candle lamps, 20-candle lamps, brackets, switches for single lamps, wiring extra lamps, lamp posts, sheathed cable per yard.

PHYSICAL SOCIETY.—Nov. 8.

Professor Ayrton in the chair.

Mr. Kavargee was elected a member of the society.

Professor F. Guthrie read a paper on "Certain Phenomena Attending Mixture." In a previous paper Dr. Guthrie had noticed the increase of volume attending the separation of triethylamine and water effected by heat. The present paper is an account of a more thorough examination of this and allied phenomena. Experiments conducted with a number of different liquids showed that mixtures can be arranged in two distinct classes. Of the first a mixture of water and ether is an example. When shaken up together they mix, heat is *evolved*, and a *diminution* of bulk takes place. If any excess of ether present is poured off, and the lower clear liquid *heated* in a sealed tube, it becomes turbid owing to the separation of the ether. This is accompanied by an *increase* of bulk and *absorption* of heat. Triethylamine and water and diethylamine and water are mixtures belonging to this class; the temperature of separation is a function of the ratio in which the two liquids are present. A typical case of the second class is a mixture of alcohol and bisulphide of carbon. These mix with one another in all proportions above 0°C. with *increase* of bulk and *absorption* of heat. Upon being *cooled* to about 17°C. they separate. The separation of a mixture of ether and water and of a mixture of alcohol and the bisulphide was shown. In these cases the action is regarded as a chemical one, and generally an excess of one liquid or the other is present. To determine the combining proportions two methods are used. In the first, a number of mixtures of the same two liquids in different proportions were taken, and the rise or fall of temperature produced by their mixture measured. When this was a maximum there might be assumed to be no "dead matter" present. In the second method, which is more delicate, but more laborious, and which was used when the approximate combining proportion had been found by the first, the change of volume produced by mixture was noted; when this increment is a maximum the liquids are present in their combining proportions. These experiments gave very concordant and definite results. For example, that the molecular compound of ether and carbonic sulphide is represented by the formula $C_4 H_{10} O, 2 CS_2$, and that of chloroform and carbonic sulphide by $C H Cl_3, C S_2$. A striking confirmation of this view is afforded by the behaviour of the vapour tension of a mixture. The temperature being constant, if the vapour tension be plotted with the percentage of the more volatile liquid as abscissæ, the curve is, for a mixture of two liquids which have no chemical action upon one another as the iodide and bromide of ethyl, a straight line. For ordinary mixtures, however, this is not the case. A curve is obtained in which there is observable at a certain point an irregularity. The abscissæ indicates the molecular combination found by the previous experiment.

Dr. C. R. Alder Wright read a paper by himself and Mr. C. Thompson on "Voltaic and Thermo-voltaic Constants." In a former paper the authors had stated that in a cell set up with two metals immersed in pure solutions of their corresponding salts, a given increment in the strength of the solution surrounding the metal acquiring the higher potential causes an increment (a) in the E.M.F. set up; (c) while an increment in the strength of the other solution causes a decrement (b) in the E.M.F. This law is now substantiated; it is, however, found that for dilute acids instead of metallic salts (b) may be negative. The authors also find that it is possible to represent the E.M.F. of a cell by the difference of two quantities, which they term the voltaic constants. These are quantities relating to each plate and its surrounding liquid. The voltaic constant of a metal and a liquid is a function of the nature of the metal surface, the strength of the solution, and the temperature, but is independent of the opposed plate and its liquid; it is practically defined as the E.M.F. set up when opposed to a zinc plate in a solution of the corresponding zinc salt of the same molecular strength. The authors further conclude that the E.M.F. of a given combination usually *stands in no simple relationship to the chemical action taking place in the cell*, but that it may be expressed by the sum of the mechanical equivalent of the chemical action per electro-mechanical equivalent, and the difference of two quantities, one being related to each metal and its surrounding liquid, and being constant for that metal and liquid *termed thermo-voltaic constants*. This thermo-voltaic action may act with or against the chemical action in

Digitized by Google

producing E.M.F. In some cases, as in that of a cell composed of iron in ferrous sulphate and cadmium in cadmic sulphate solutions, the E.M.F. is against and greater than that produced by chemical action, consequently the cell works backwards with absorption of heat. At the close of the paper Professor Ayrton and Dr. Guthrie remarked upon the apparent exception here shown to the second law of thermo-dynamics.

COMPANIES' MEETINGS.

Edison and Swan United Electric Light Company (Limited).

A general meeting of the shareholders in the two Companies which have been amalgamated under the above title was held on the 11th inst. at the Cannon-street Hotel, under the presidency of Mr. James Staats Forbes.

The CHAIRMAN, in opening the proceedings, said he would relieve the Secretary of the ordinary duty of reading the notice convening the meeting, the precise nature of which it was very necessary that they should know. It was not in any sense a legal meeting—it was more in the nature of an invitation on the part of the Directors of the new Company to the separate members of the old Companies, in order that they might learn the position of the United Company at the first annual occasion when it was possible to place it before them. The legal meeting of the United Company had already been held. The accounts had been audited and submitted, and a report had been drawn up; but the legality of the concern, so to speak, being vested for the time being in the hands of the Directors, they had thought it would be highly improper to take any decision on the report or the accounts. They therefore determined that the report and accounts should be sent to the respective shareholders of the separate Companies, and that they should be invited to attend that meeting that day substantially to hold a meeting of the United Company, with the drawback that any decision they might take there was not legally binding on any one.

A SHAREHOLDER: Then we are like ciphers.

The CHAIRMAN: Oh, no.

The SHAREHOLDER: Are the accounts to be passed to-day?

The CHAIRMAN: You will hear. The legal meeting had been adjourned pending the present meeting and the separate meetings of the two Companies, because after that meeting there was to be a Swan meeting, and he presumed that there would be an Edison meeting.

A SHAREHOLDER: Shall we have the power of being present, or any control over our own business?

The CHAIRMAN: The Directors, acting for you as trustees——

A SHAREHOLDER, interposing: Is that all?

The CHAIRMAN, continuing, said he thought it was a great deal. He could not himself give any better guarantee for the power the shareholders would have than that the Directors had invited them there that day to express their views. They wished to know by that meeting what the majority of the proprietors wished to have done, and if it were something which the constitution of the Company enabled the Directors to do, he supposed that they would do it. That being so, he would proceed exactly as if it were an ordinary meeting of the proprietors duly convened. The reason they were not called together as a meeting of the shareholders in the Edison and Swan Company was that it had been impossible hitherto, either on the part of the Swan Company or the Edison Company, to distribute to individual proprietors the shares in the new Company taken over *en bloc* by the two Companies. The reason the Edison Company had been unable to distribute their shares was that it was necessary first of all to liquidate their Company; and the reason the Swan Company had not been able to distribute their shares was that they had only parted with a portion of their business. Their shares in the United Company represented their English patents, but they had reserved for themselves their foreign patents; and what the Swan Company would have to do later on would be to see what machinery was necessary to cut up the present shares, so that one portion might represent the holding in that Company, and the other portion their separate interest in the foreign patents. There had been great difficulty in the cutting up of the shares, and this had increased the responsibility of the Directors, and until they could by proper and legal process distribute the shares to the shareholders in each Company they must bear that responsibility. Of course, as soon as that could be done it would be done, and then those present—some he supposed representing interests in the Swan Company and others interests in the Edison Company—would come to the meeting as to an ordinary meeting—they would come as shareholders in an ordinary company with all the powers which shareholders usually enjoyed. Practically, however, they were there that day with as much power as if they possessed legal powers to vote, as their decision would govern the acts of their trustees, the Directors. They were all familiar with the reasons for the amalgamation of the two Companies. The shareholders in the Swan Company had had the arguments placed fully before them, as, he presumed, had also been the case with the Edison shareholders. The two concerns were started independently of each other, each with a good name as a trade mark, and each with separate and distinct patents. The two Companies went on, as such companies usually did, "puffing" their wares, trying to make their own business, proclaiming each to be the right thing, and they had really commenced litigation as to the value of the patents, the Edison Company insisting that the Swan Company were infringers, the Swan Company insisting that the Edison Company were infringers. Fortunately some of the people connected with both of these Companies had gone through in other companies experience almost on all fours, and they knew what was to be expected from prolonged litigation. They therefore counselled not quarrelling or division, but a fusion of interests, and that principle was eventually adopted. Then there came a great practical difficulty. It was very easy to talk of combining two undertakings, but when they came to the question of values every one knew how buyer and seller differed in opinion. It was a difficult matter under ordinary circumstances, but in a case where the value was speculative, as in this instance, the difficulty was greatly increased. The Swan Company had paid a very large sum for their patents, and they were supposed to be invulnerable, and to lead to a business which by and by would be of enormous value. That was the theory of the Swan Company; and the Edison theory was precisely the same. After a great many suggestions, and after occupying the brains of certainly some not the least able men in London, or the least experienced, what was determined was this. It should be assumed that each of the Companies had acted *bona fide* in the purchase of their patents, and in the manner in which they had carried on their business; that all the patents should be put together and one strong Company formed, litigation avoided, and the business fostered and established. That was the principle they had determined to act upon, and having settled that principle all that they had to do was to take reasonable pains to see what money had been spent. The Directors, therefore—very wisely, he thought—put the matter into the hands of probably two of the most capable men in London—Mr. Welton, of the firm of Quilter, Ball, and Co., he representing the Swan Company; and Mr. Price, of the firm of Price, Waterhouse, and Co., he representing the Edison Company. It was on the report of these gentlemen, after a full and proper examination, that in the fused Company the respective portions of shares were allotted for distribution to the shareholders of the two Companies. Upon that being ascertained, an agreement was entered into, carrying out all the details of the fusion, determining in the most express language possible the conditions—monetary and otherwise—under which the affair was to be united, and that agreement was submitted, as it was legally bound to be, to separate meetings of both Companies. He remembered that he was rather verbose on that occasion in making it clear to the shareholders what they were doing in going into the union. They had now settled the shares which the partners were to have; and the Swan Company had taken a larger proportion than the Edison Company, because, wisely or unwisely, they had spent more money. Then the question arose, how was the machinery to be carried on? There were numberless points in connection with this question. They had not only to settle their relations as between themselves, but with persons outside. There were very large establishments—two sets of directors, two sets of officials, two sets of premises, and so on. The administration, by the articles, was submitted to delegates of four Directors, appointed by the Edison Company, and four appointed by the Swan Company, and as soon as that Board was formed they got to work, and they had done a great deal of useful work. Very much against his own will he had been induced for a time to fill the onerous position of Chairman of the Company. The Chairman of the Edison Company was Sir John Lubbock, who was known by every one to be a very distinguished man and of such high standing as to entitle him to the confidence of the outside world. Originally he had hoped that Sir John Lubbock would take the chairmanship of the United Company. That gentleman was Chairman of the Edison Company, and he (the speaker) was Chairman of the Swan Company; and although in the subdivision of the new shares the Swan Company had the larger proportion, he considered that he ought to sacrifice what might have followed as a kind of natural claim in the selection of directors and most willingly have yielded precedence to Sir John Lubbock. Unfortunately, however, family and other matters had made it impossible for Sir John to fill the position of Chairman, and he had himself been—he would say generous or weak enough to take upon himself the burden of the position for a year. The other Directors appointed were Lord Anson, Mr. Leyland, Mr. Arnold White, and Mr. Bidwell, who were appointed by the Edison Company; the Swan Company delegating himself, General Trevor, Mr. Villiers, and Mr. Batt. Those eight gentlemen from the time of the fusion had taken charge of the business. What they had had to do during the months which had elapsed had been to turn it all inside and out, to find out what there was in it, to eliminate the bad and keep the good, to fuse the establishments, and to bring down the accounts into something like tangible and reliable figures, and having done that, within the prescribed legal time to hold their first ordinary general meeting, which they had done, but which they had deferred taking any resolution on until they had had the opportunity of submitting it to them. The shareholders had before them the outcrop of all their efforts, and they also had for the first time a balance-sheet and statement of accounts of the United Company, which, whatever qualities it might have in the estimation of the shareholders, the Directors could submit as being reliable and verified figures, describing the position in which the Company now stood. In those figures, disagreeable as they were, there was nothing disagreeable which was in the least extenuated. Turning to the report of the Directors, he observed that it was the first annual report, and its object was to make the individual proprietors acquainted with the position of the United Company. As was stated, the wisdom of the amalgamation was confirmed by a special meeting of both companies, and the agreements were also in both cases unanimously approved. The statutory meeting of the new Company was held on the 29th of January last, at which the then position was explained pretty fully. The report explained what the position was at the precent time, and showed what the Directors had had to do; and the reason the financial result in the profit and loss account was not at all what they might have hoped for was indicated. Included in the capital of the Company (£353,478) was £85,695, representing 17,139 shares of £5 each, fully paid up, representing a corresponding number of fully paid-up shares in the former companies. The difference between the Swan

Digitized by Google

Company and the Edison Company was this, the Swan Company had paid out and out a very large sum of money for their patents, as well as a considerable number of fully paid-up shares, while the Edison Company had purchased Mr. Edison's patents chiefly in virtue of a deferred payment. He had no hesitation in pronouncing that the Edison Company were much wiser than the Swan Company, because when one paid down a lump sum of money for an invention in its early stages, he in fact became the insurer of that invention—he made the inventor perfectly safe without taking any risk. That was what the Swan Company did. The Edison Company, however, paid Mr. Edison for his invention chiefly in this way: we will find the money and take the risk of developing the business, and if by means of your brains we make a successful business, when the interest on the capital which has been spent to make it a success has been covered, you shall come in for a large share of additional profit. In fact, one of the greatest inventors of modern times, backed by some very keen people who were not inventors but financiers, had thought so well of the business that they put themselves behind a 7 per cent. cumulative dividend over a very large sum of money for their consideration. They had this great faith in it, and he hoped that their faith would be justified, because when it was the gentleman who then addressed them would be able to point to such results that his task would be a very easy one. They had creditors to the extent of £19,937, and this brought up the whole capital and obligations of the Company to £373,000. On the other side they had endeavoured to analyse this amount as much as possible, because it was very desirable that gentlemen interested in the concern should know as much as the Directors. The thing, as it stood at present, was made up of two quansities, or factors. One was the indefinite, the other was the positive, and in the balance sheet they had endeavoured as far as they could to separate the indefinite from the positive. In doing this they had loaded the indefinite as far as they had thought prudent, and they had brought down the positive to the lowest limit. They might be sure that the liquid assets represented the least and not the most value. What did the affair cost—the purely speculative part of it? The cost of the patents, preliminary outlay, and other items not represented by money or tangible assets taken over was £174,000. He did not know whether the brains of Mr. Swan and of Mr. Edison, as concreted in these patents, were worth £174,000, but that was what they had cost them. Then there had been the expenditure in carrying the thing on. They had shares in the Manchester and District Edison Company—people who were to find the capital for exploiting the business; and when that capital received a certain amount of dividend the profits over and above were to be divided between themselves and the Edison Company. That asset was represented by £12,000 in deferred shares of the Manchester Company. Upon one hypothesis that asset might be worth £12,000, but they could not get that amount for it to-day. The fusion of the Swan and the Edison Companies had involved some delay in the confirmation of this agreement, because it was with the Edison Company pure and simple, and for the use of the Edison patents. The agreement had had to be modified, and the Manchester Company could now use the Swan patents—a privilege for which this Company had received value. As to the item of rental installations, plant, &c., he had before described what an installation was. The key of the position was the lamp. They might have the most charming engine, the most excellent machinery, the most admirable leads, but everything was subordinate to the lamp. The outlay on that part of the machinery was out of all proportion to the rest. The two Companies had entered into two classes of business. First of all, they made and sold lamps, and they undertook to erect installations and to light certain places at per annum—that amount not only producing the lamp but doing all the preliminary work. Both of the Companies were under contracts of that character. They had found it necessary, to form these installations, to spend £77,251. That was a very large sum, and there was this unsatisfactory element about it—that with their present knowledge he had no doubt that that outlay would have been materially less. They must remember what this business was. It was a business in a constant state of transition. The very machinery by which they began was being supplemented by other machinery more effective and less costly; and there was no doubt that that £77,251 would have to be written down a great deal unless they dealt with it as money or power-producing machinery. They had discovered that rental installations represented very bad business. The public, however, had to be educated, and taught that they could light up their houses, and theatres, and perhaps their streets in this fashion, but they would not believe it until they were shown. They therefore had to be shown, and that seemed to be the principle which dominated many of these installations. Where the installations were paid for at once the matter was different. There the risk was borne by the people who had the installations. The Swan Company, through Mr. Crompton, did the installation at the Law Courts. There there was a profit. The same remark applied with regard to installations on ships—they paid the cost of the fittings. With respect to the lamps, they were, as he had said, essential to both these descriptions of outlay, and this apparently was the most profitable part of the business at present. If the Company were to be wound up to-morrow, and the £77,241 had to be realised, it would not produce this amount by a very long way. The chief use of this expenditure had been to demonstrate to the world that the electric light was possible, and to identify with that demonstration the name of the Edison and Swan Company, and at the same time to warn the Edison and Swan Company that that was not a description of business they need be very anxious to obtain. He supposed that their policy in future would be to devote themselves to installations on the theory of being paid for the installation itself and not as rent, and to the manufacture and supply of lamps. The outlay on the factories had been a necessary expenditure, and it had left them possessed of factories of great productive capacity. Including the depreciation of £2,310, the balance showed a loss of £28,214. That was the end of the speculative portion of the assets. It meant this, that they had £300,000 in round figures locked up, represented by nothing very tangible—the great part of it certainly not very tangible,—some portion of it which would have a value by conversion and ultimate sale. All of the items of £77,000 odd to which he had referred were not lost, though a good deal of it was lost in the sense that it would not realise this amount if sold to-morrow. They had taken into this first sub-division all the risks they could. They had got for this £300,000 their patents, a first-rate manufactory, where a great many lamps were being produced; they had a trained staff, who were beginning to understand the work, and they had a Board who knew a good deal more to-day than they knew a year ago. The shareholders themselves would also have got a little wisdom, too—that was, that there was enormous risk in taking up patents of any kind and running all the risk of working them out for the benefit of the inventor. That lesson had been learnt in other things besides the Edison and Swan Company. He himself held a great many shares in the concern, and personally he was not disconcerted. They then came to the tangible assets, to which he referred *seriatim*. As to the plant and stock, it consisted of a great number of lamps, stores, materials, &c., valued at £23,900. He was assured by their admirable manager, Major Flood Page, and their accountant, that that £23,000 was a good deal within the value of the plant and stock if it had to be sold to-morrow. As to the item of debtors £32,000, he might say, as an evidence of whether these accounts were good or bad, that a great deal of the item had already been realised to the extent of twenty shillings in the pound. The cash in hand and at the bank was £4,000. That was the state of the case; and he believed he had exhausted the matter, subject to any cross-examination they might like to submit him to. The salient figures were £301,000 for patents, advertising, foundation charges, knowledge gained up to that moment, the rest being money invested in carrying on the business, which they believed might be carried on, with their present knowledge and under proper prudence, at a profit. They then came to the profit and loss account, which dealt with the year ended the 30th of June, 1884. Having gone through the various items he observed that the difference between the two sides was a loss, including depreciation, of £28,000. That was the outcrop of the year's business, and a very bad outcrop it was, if, as he had said before, there were not some rational grounds underlying it. It was a thoroughly fair and proper statement. As to the future of the concern [a Voice: "That is the point"], he was not particularly anxious to devote his time and money to develop a concern which he believed to be bad. As he had said before, he for one thought—and he believed he would have the concurrence of the Board in the remark—that the affair was not so bad that it ought to receive the *coup de grâce* on the statement which he had made to them. If it were so bad that every time they met they would show a loss of £28,000, he would say the sooner they put an end to the thing the better. He saw several gentlemen present who were very deeply interested in this Company, in money and reputation, and he knew of others similarly situated, who were absent, who had not lost confidence in the enterprise. He thought they had reasonable ground for the belief that some of the largest proprietors, notwithstanding the outcrop of the accounts now presented, did not take a despondent view. In fact he supposed it could be said that they had arrived at the condition of things which was called "turning the corner." They had tried to get some test of that by their experience of the working of the first quarter of the current year. When one had to write a report which was not altogether flattering or agreeable, one endeavoured to find a crumb of comfort to throw in. On page 3 of the report it was stated, "The books have been balanced to the 30th of September, as may be seen by the accounts which accompany this report, and the serious loss attending past work has disappeared." For what it was worth, that was a crumb of comfort. There was the balance sheet got out for the first three months of the current year, and at the bottom of it it showed that the balance of profit for the three months was £752. That figure multiplied by four represented £3,000, so that supposing the other three quarters of the year which had to elapse between September 30th, 1884, and the end of the financial year produced the same results, instead of showing a loss of £28,000 upon the year's business, there would be a profit of £3,000. That was the beginning of what they called turning the corner. They had paid the large sum which he had mentioned of £300,000 in the acquisition, and up to the present time the manifestation, of these patents. Of course the patents were being infringed. A number of clever people were playing what was called a "waiting game." They left the heat and burden of the day to be borne by others, at whose expense they afterwards shared the fortune of those first in the field. They had several of these persons now to deal with. They had had to resort to some proceedings to establish their patents. The two Companies would have had to resort to similar proceedings if they had not fused, the difference being that this Company had now both sets of patents, the one to help the other. Their chance was thus increased against outsiders, not as two to one, but enormously by the fusion of these interests; and they trusted that the Company would go on and establish the value of the patents held by them. If those patents were established they would have a property. They were not talking without knowledge in this matter, because the thing was on all fours with the telephone. There was an exactly parallel case—two inventors, Mr. Bell and Mr. Edison; two companies, the Bell and the Edison; two sets of litigants, and an amalgamation; and what had been the result of the fusion? After a very bad start, and having to fight the patents in every court of law, they had been confirmed, and the telephone in this country was not altogether an unsuccessful venture. It was very odd that the parties in the two instances should be in some respects the same. They had to beat the infringers; and the very same counsel who won in the one case were the very same counsel who protested against winning in the other. If so, well and good; and meanwhile, he was bound to say that the infringers, at their

Digitized by Google

personal risk, were laying the foundation of the future business of the Company. Messrs. Woodhouse and Rawson, who were mentioned in the Directors' report, were, he said, the most active of the infringers. They were young men, and were very energetic in making business; and they were making and selling a great many lamps. The Court of Chancery had, however, made them give an undertaking that they would keep an account of the lamps, and if the Company succeeded in establishing the value of their patents Messrs. Woodhouse and Rawson would have "to cash up." If any one of the proprietors wished to wash his hands of the concern well and good, but the Directors were desirous that he should understand the position. They had to establish the patents and see if they could carry on the business at a profit. The Directors thought that the Company could do both, and their advice was to go on. They had to make up their minds what sort of business they were going to do; and, as far as the Board were concerned, they were not going to do any more speculative business. They knew all—or a good deal—about their lamp and about installations. They were not going to carry on installations on the rental system—they would sell, not rent. As to public installations and provisional orders, the Board of Trade had engaged themselves with the entire system, and had laid it down that the electric light was to be utilised in the public interest. They were very much afraid that it was going to run away with every one, and they felt that it was likely to become such a frightful monopoly that it must be tied up in every way. In fact, the poor public, not knowing how to take care of themselves, were to have all the support of the Board of Trade. Having got provisional orders they knew what they were worth—nothing; and the conclusion they had come to was that these provisional orders and the Electric Lighting Act was an act for making public lighting impossible, and they were not going to enter on any risk connected with it. They had stated their reasons for their decision to the President of the Board of Trade. There was, however, a great deal of business to be done at a profit. House-to-house lighting had exploded. Every man who was an inventor must be imaginative. When they came to predict about street lighting, and so forth, they had made the most awful blunders. He was not going to throw stones; but if the people who had found the money for these undertakings had not been quite so impressed with the imaginative qualities of the inventors they would not have paid so much for the inventions. This Company were not going to buy any more inventions in that way, or undertake the kind of work involved in street lighting or house-to-house lighting, or do any other lighting but that which paid. With that general principle before them their conviction was that, notwithstanding the disappointments, notwithstanding that their shares had no value, notwithstanding the difficulties which faced them, there was a reasonable ground for believing that, prudently managed, the concern might retrieve itself and present a very good future. A great deal of this would turn on establishing their patents, but setting that aside, on open business, with no patent at all, working with the strength of the names of Edison and Swan, and with the experience they had acquired, they ought to be able to do better than any competitor; and, assuming that the patents "vanished into thin air," he was not inclined to believe that this chestnut might not yet be taken out of the fire and a good business established. It was in that conviction that they suggested to every one concerned the propriety of re-forming the Board and going on on their reformed plan. According to the Articles of Association, the Board retired *en bloc;* and he had no doubt that they were all quite willing to retire if that were the desire of the shareholders. On the other hand, he supposed that, as honourable men, having assumed the responsibility of conducting the affair so far, they had enough self-respect left to be quite willing—some of them at great personal sacrifice of time and labour—to go on and see whether it was possible to put the thing on a sound basis and retrieve it. That was a point for the shareholders to decide. It was not a legal meeting for that purpose, but an intimation from the shareholders as to what they wished would receive the respectful attention of the Board. He had no resolution to propose, but he would be very glad to put it to them as a matter of form that the report and accounts be received. The moral effect of the verdict of the meeting would be exactly the same as the legal effect.

Viscount ANSON, on behalf of his colleagues of the Edison Company, said that he had listened to the Chairman's statement with great attention. He thoroughly acquiesced in all that the Chairman had said, both as to the causes which had led to the great loss they showed on the last year's trading, and also as to the possibility and even the probability of the concern being eventually turned into a somewhat profitable one. He thought it would be a great mistake if they now made up their minds to stop the Company altogether. If they could only hold their own for a short time, he believed that there was a possible and a probable chance of their doing well. He thought all the Edison shareholders must be fully aware that that Company had been put into liquidation. The Directors had done their best to bring about that result, and the entire affairs of that Company were now in the hands of the liquidator, who, he hoped, would shortly see his way to give them their shares in the United Company. He desired to state how thoroughly fair they had been received by their colleagues of the Swan Company.

Mr. KEMPSTER said that the Chairman had stated that he wished to know the feelings and wishes of the shareholders of the amalgamated company. He (the speaker) knew of no way of doing that except in some form of resolution. Therefore, at the request of some large holders in the capital of the Company, he took on himself to move the following resolution:—"That in the opinion of this meeting it is desirable that a committee of, say, seven shareholders, with power to add to their number, should be elected, who shall fully inform themselves as to the past working of each of the two Companies prior to their amalgamation, the present position of the United Company, and its prospects of successful working; also that such committee should confer with the Directors, and, if deemed necessary, report to the shareholders as to any steps considered by them advisable for placing the Company upon a sound commercial basis." He moved this resolution not at all in an unfriendly spirit towards the existing Board. He submitted with great respect that the present condition of the Company was such that the shareholders had a right to obtain independent information, and the only way of obtaining such information was from an independent source. He contended that they ought before now to have had the shares distributed among them.

Mr. SUDWORTH seconded the motion, observing that the installations at King's Cross, Mansion House, Bricklayers' Arms, and other places which were taken over by the Swan Company "were murdered and thrown away."

The CHAIRMAN stated that the experience of the Directors of the installations which they took over from Mr. Crompton did not justify the statement of the hon. shareholder. They did not pay either Mr. Crompton or the Company, and they were very bad bargains.

Mr. TIPPING objected most strongly to the appointment of the committee proposed.

Sir JOHN LUBBOCK, M.P., endorsed the view of Mr. Tipping. He added that he by no means took the hopeless view of the position of the Company which some appeared to do. It was, he argued, too early to judge of what the future of the Company would be until they saw the result of the actions against the infringers; but he was glad to hear the Chairman say that if those actions went against the Company he would not lose hope.

After some further discussion,

Mr. KEMPSTER, in deference to the feelings of the meeting, withdrew the resolution.

The CHAIRMAN said that if the resolution had been pressed the Directors would have opposed it tooth and nail. So far as regarded the issuing of the certificates, the Directors were most anxious to do so, and they would be issued as soon as practicable.

On the motion of Sir J. LUBBOCK a vote of thanks was passed to the Chairman and Directors, and the proceedings then terminated.

NOTES.

BRUSSELS UNIVERSITY.—Last week this establishment celebrated its fiftieth year of existence.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 14th Nov. amounted to £4,291.

PERIM.—In a note in our last issue, Perim was inadvertently stated to be off China. Most of our readers would know that Perim is an island in the mouth of the Red Sea.

ELECTRIC LIGHT AT MADRID.—The Madrid Electric Lighting Company has completed thirty-five installations, with 127 arc and 323 incandescent lamps in the city alone.

ELECTRIC LIGHT ON BOARD SHIP.—MM. Sautter, Lemonnier et Cie., of Paris, have undertaken the lighting of the Messageries Maritimes steamer "Océanien" with 150 Edison lamps.

ARTIFICIAL LIGHTING AND HEALTH.—The paper read by Mr. Crompton on this subject at the Healtheries Conference, together with the discussion thereon, has been issued in pamphlet form.

THE GROSVENOR GALLERY.—It will be seen from our advertisement columns that tenders are required for lighting these rooms by the electric light. The tenders are to be in by Saturday next, the 29th inst.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th Nov. are £2,123, as compared with £2,331 in the corresponding period of 1883.

ELECTRIC LIGHT IN SPINNING MILLS.—Last month, the Société d'Appareillage Electrique, of Geneva, installed forty-four 10-candle Edison lamps, maintained by an Edison dynamo, in the Lorze spinning mills, Canton of Zug.

ELECTRIC LIGHT AT LINLITHGOW.—On account of considerable increase in the cost of gas to the ratepayers, negotiations are going on with some electric light companies as to first cost and current expense of electric lighting.

ELECTRIC NEWS COMPANY.—Mr. W. J. Burnside and Mr. B. P. Daniels, the liquidators of the Electric News Telegraph Company, announce that all creditors of the company whose claims have been admitted will be paid in full.

ELECTRIC LIGHT AT GOODS STATIONS.—The goods station at Bromberg, in Germany, is illuminated by four arc lamps, and this installation will probably be followed by the application of the electric light to all the station buildings.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts for the week ending 14th Nov., 1884, were £3,393, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Tele graph Company.

HARTLEPOOL.—The Central Marine Engineering Works of West Hartlepool, having purchased from Messrs. Gray and Gladstone, of the same town, their Brush 16-light apparatus, have entrusted the erection of it to the Hammond Electric Light Company.

EARTHQUAKE AT CLITHEROE.—A severe shock of earthquake was felt at Clitheroe at ten minutes past 5 o'clock on Tuesday evening. A report like thunder is said to have been heard at the time of the shock, while a lurid glare was observed in the sky.

TORQUAY.—Negotiations are being carried on between the Torquay Improvement Committee and the United Telephone Company to establish a telephone exchange in Torquay. The company require 100 subscribers to start with, and the subscription is £12 per year.

ELECTRIC LIGHT IN PARIS.—The Paris Municipality has decided to prolong to the 18th May, 1885, the arrangement made with the Société Lyonnaise de Constructions Mécaniques et de Lumière Electrique for lighting the Place du Carrousel, at an expense of 16,912f. (£676).

EDISON'S INDIAN AND COLONIAL ELECTRIC COMPANY.—A petition for confirming a special resolution reducing the capital of this company from £250,000 to £117,500 has been presented to the High Court of Justice. The list of creditors is to be made out as for the 28th February, 1885.

ELECTRIC LIGHT IN LONDON.—The Streets Committee of the City of London have accepted the proposal of the Hammond Electric Light Company to undertake the lighting of streets in a district, and this company will have the right of private lighting in the district which they take up.

NEW CABLE IN ITALY.—The Italian Government has given notice that a submarine cable has been laid from Calato Point Island of Capri, in the Bay of Naples, across the Bocca Piccola, to the mainland. This supersedes the semaphore at Massa Lubrense, the station there being consequently discontinued.

CHARING CROSS AND WATERLOO ELECTRIC RAILWAY.—The promoters of this railway, which was sanctioned by Parliament in 1882 for the purpose of constructing an electric railway from Waterloo Station, passing under the River Thames to Northumberland-avenue, have decided to abandon the authorised railway, and to dissolve the company.

DEATH OF M. LATIGUE.—The Société Générale des Téléphones has sustained a great loss in the death of its director (general manager), M. Latigue, who was engaged for the greater portion of his life with the Northern Railway of France, but subsequently contributed in a large measure to endow his country with the first telephone systems.

JOINT FOR CONDUCTORS.—R. W. Kear, of Pottsville, Pennsylvania, connects the two wires by means of a socket furnished with a set screw. The action of turning the screw bends the ends of the wires and forces them to enter a small groove made for this purpose in the socket. This may be new in America, but it is certainly not new in England.

ELECTRIC LIGHT IN SWITZERLAND.—Besides the installation at Geneva, which we have already mentioned, the Société d'Appareillage Electrique, of that town, is about to provide the town of Aigle, in the Canton of Vaud, with a small central station for incandescent lighting, the motive power for which will be supplied by a canal which passes through the town.

BOSTON.—An electrical exhibition, to open Nov. 24 and close Jan. 3, will be held in the great building of the Massachusetts Charitable Mechanic Association. The exhibits will be classified under sections, thus: production of electricity, conductors, measurement, applications, terrestrial physics, historical apparatus, special novelties, and electrical literature, &c.

THE CREIL EXPERIMENTS.—The installation at Creil, 50 kilometres (31 miles) distant from Paris, is now terminated, as far as regards the work undertaken by the Northern Railway Company, while the receiving machines are being put

Digitized by Google

down at Paris. The laying of the conductor is, however, not yet commenced, so it will be at least two months before the experiments can be begun.

INTENSE CURRENTS.—Drs. Brouardel and Gariel, who drew up a report on the death of two young men through contact with electric lighting conductors at the Tuileries, Paris, a few months ago, have applied for a subvention of 2,000fr., or £80, from the Paris Municipal College for studying the means of preventing danger to human life from electric currents of high tension.

INTERNATIONAL TELEPHONE COMPANY.—A meeting of shareholders in the Compagnie Internationale des Téléphones is called for 29th inst. at Brussels, to consider the report of the administrative council (board of directors) as to the modifications in the statutes (Articles of Association), and the reduction of the capital by means of purchase of shares, transformation of the company, or otherwise.

ELECTRIC CLOCK AT BARCELONA.—A rich banker of this city has placed in the Barcelona Exchange a magnificent clock, connected electrically with another clock, at the makers', a distance of 650 yards off, which serves as regulator. It is proposed to place both clocks in electrical communication with the Observatory of the Academia de Ciencias Naturales y Artes, where the meridian observations are made.

EDISON AND SWAN ELECTRIC LIGHT COMPANY.—The *Bulletin* of the Compagnie Internationale des Téléphones begins its notice of the meeting of the Edison and Swan Company as follows:—"We have so often had occasion to put on record the precarious situation of many English electric lighting companies, that we are glad now to be able to speak of a company the situation of which is more favourable."

SOCIETY OF TELEGRAPH ENGINEERS.—Through the courtesy of the Eastern and the Eastern Extension Telegraph Companies, the fact of Mr. Edward Davy's election as an honorary member of the Society of Telegraph Engineers and Electricians was communicated to him by wire, and we understand that by the same means Mr. Davy has been able to express to the Society his high appreciation of the honour thus conferred upon him.

CONGRESS AT THE SORBONNE.—At the Congress of Scientific Societies to be held next year at the Sorbonne, Paris, the mathematical, physical, chemical, and meteorological sections will deal, among other subjects, with the following:—Observations of earthquakes with instruments; sheet lightning and frequency of storms in the same day; the utility, as regards weather forecasts, of reports founded on magnetic and electrical observations.

SOCIETY OF TELEGRAPH ENGINEERS.—The next meeting will be held on Thursday, 27th inst., when the adjourned discussion will be taken on the following papers:—"On the Theory of Alternating Currents, particularly in reference to the Alternate-Current connected to the same Circuit," by J. Hopkinson, F.R.S., member; "An Account of Experiments with Alternate Current Machines," by Professor W. Grylls Adams, F.R.S., president.

THE TELEPHONE AND THE CHOLERA.—The Administrative Council of the Société des Téléphones has decided that messages respecting aid for those attacked by cholera in Paris, whether subscribers or not, shall be sent free of charge. The central offices are in telephonic communication with the Prefecture of Police and the twenty Mairies. At the last meeting of the Paris Municipal College, M. Lyon-Alemand urged that all the hospitals should be connected with the telephone system.

INVENTORIES, 1885.—The Society of Arts' *Journal* has been constituted the official record of the International Inventions Exhibition to be held next year, and will consequently publish all the official notices and other information. In consequence of a request from several foreign countries, the time for receiving foreign applications has been extended to 1st December, and in the case of the United States to the 31st December. It is stated that between 4,000 and 5,000 applications have come from Great Britain.

ANTI-BURGLAR ELECTRICITY.—Messrs. Eck, Callow, and Co., of Dean-street, Holborn, who recently fitted their electric fire alarms to the Natural History Museum, have brought out Harrison's Patent Burglar and Fire Alarm. This consists of an apparatus to be placed near the top of a building, and put in electrical connection with all accessible doors and windows. On one of these being opened, or even a pane of glass being smashed, a loud report is caused, and a bright light ignited, which lasts for a considerable period.

NATIONAL TELEPHONE COMPANY.—We are officially informed that the long pending dispute between the National Telephone Company and Messrs. D. and G. Graham has now been amicably settled. Arrangements have also been made whereby the Telephone Company now executes all the work in the Glasgow district, for which Messrs. D. and G. Graham have hitherto been the contractors, and consequently has now the whole of the construction and maintenance work under its own control throughout all its territory.

POST OFFICE EXTENSION.—The *City Press* says: "It is proposed to make an entire clearance of the buildings between the northern end of the new Post Office and the Money Order Office, thus absorbing nearly, if not quite, the whole of Bull and Mouth-street, with its private business houses and railway booking-offices, and some half-dozen houses in King Edward-street, while two other large buildings, one of a sacred and the other of a secular character, are also included in the general sweep. These are the French Protestant Church and the Queen's Hotel."

TELEGRAPHY AND TELEPHONY ON THE MIDLAND.—In the article bearing the above title which appeared in our last number, it is stated that a few Hammond arc lamps are used for lighting the telegraph works. This is incorrect; a few Hammond incandescent lamps only are interspersed with the Swans. The following statistics are interesting. The Midland Company employs, on its telegraph system, 15,100 miles of wire, 1,556 single-needle instruments, 3,890 block instruments, 2,500 block bells, 1,010 signal repeaters, 380 light repeaters, and 860 other instruments.

PET OF THE TELEGRAPHERS.—The *Chicago News* says that, a year ago, Lizzie Annandale, "the beautiful and vivacious contralto," of the Abbott Opera Company, got up a concert in Baltimore for the benefit of the telegraph operators engaged in the famous strike which then prevailed throughout the country, raising 2,500dols. (£500) by the venture; and since that time she has received the most flattering courtesies from the fraternity wherever she goes. "This simply goes to show," continues our contemporary, "that the telegraph operators are mighty well organised, and that they do not forget a kindness."

NEW APPLICATION (?) OF ELECTRIC LIGHT.—The Paris *Figaro* gravely informs its readers that an inventor has conceived the idea of transforming divers maritime routes into

Digitized by Google

immense boulevards, illuminated by electric lighthouses, erected on quasi-islets, floating and incapable of being submerged, which are to be kept in communication with each other and the continents generally by submarine cables. Voyages will thus become mere maritime promenades, ships being guided on their course by a luminous "arc," produced by parabolic mirrors reflecting the rays of the sun or those of electric lights.

EDISON COMPANY, NEW YORK.—The selection of the board of trustees has not been altogether plain sailing. It is said that two lists were at first prepared—one by the existing board of trustees and the other by Mr. Edison, but a compromise has been reached and a combination list prepared, which is understood to be satisfactory to both sides. The list is said to be as follows:—Edward D. Adams, James H. Banker, Charles H. Coster, Eugene Crowell, C. E. Chinnock, Thomas A. Edison, W. L. Garrison, Edward H. Johnson, Francis R. Upton, Charles Batchelor, Spencer Trask, J. Hood Wright, and Erastus Wiman.

THE LATE POSTMASTER-GENERAL.—Mrs. Henry Fawcett and Philippa Fawcett desire to offer their most earnest thanks to all the officers, both male and female, engaged in the postal service throughout the country for the affectionate sympathy so spontaneously shown to them in their present great sorrow. It has been a solace to Mrs. Fawcett in her grief to know how deeply her dear husband's character and influence were valued throughout the department; and it will be a real source of consolation to her if she is able to believe that his influence is still felt, and that all those things that work for good in the department are permanently strengthened by her husband's work there.

BOOKS RECEIVED.—"Bell *v.* Drawbaugh," three vols., Mudge and Co., Boston; "The Disk, a Prophetic Reflection," by E. A. Robinson and G. A. Wall, Griffith, Farran, and Co.; "Exercises in Electrical and Magnetic Measurement," New Ed., by R. E. Day, M.A., Longmans, Green, and Co.; "Magneto-Electric and Dynamo-Electric Machines," by Dr. H. Schellen. Translated from the 3rd German Edition by N. S. Keith and P. Neymann, Ph.D., with additions by N. S. Keith. Vol. I., with 353 illustrations, D. Van Nostrand, New York. "Patents and Electricity," by R. G. Dubois, C. W. Brown, Washington, giving information about taking out patents in the States and notes upon electric light patents.

CONSERVATOIRE DES ARTS ET METIERS.—In giving the programme of lectures for the ensuing winter at this renowned Paris institution, we commented on the absence of a special course of instruction in electricity. We find, however, that Professor Becquerel's lectures on Applied Physics, given on Wednesdays and Saturdays, will deal with the general properties of electricity, applications of electricity to the arts, voltaic batteries, induction apparatus, dynamo-electric machines, transmission of power, electric lighting, electro-metallurgy, telegraphy, telephony and electric clockwork; while Professor Tresca's lectures on Applied Mechanics will include "other receivers" than steam and gas engines, and also the transmission of power to a distance.

PRIZES OFFERED BY THE SOCIETE D'ENCOURAGEMENT.—Among the competitions opened by the Société Nationale d'Encouragement pour l'Industrie Nationale, France, are three of special interest to electricians, and open to foreigners. But the communications must be sent in to the secretary, 44, Rue de Rennes, Paris, before the 1st January next. A prize of 3,000f. (£120) is offered for a method of transmitting to a long distance natural mechanical forces, the position of which prevents them from being turned to account directly. A prize of 1,000f. (£40) is offered for the construction of apparatus for transmitting to a distance an indication of the temperature of a heated chamber. A prize of 3,000f. (£120) is offered for strong and simple apparatus capable of announcing, safely, regularly, and automatically, the passage of a train, at any distance.

INFLUENCE OF BATTERY INSULATION.—Donald MacNab thus terminates an article on the above subject in *L'Electricien*: "What is manifest from all this, is the advantage of strong resistances of comparison of 1,000 megohms and over. These resistances are constructed in the following manner:—On an ebonite cylinder is traced a helicoidal groove, afterwards filled with a carbon paste. The contacts are obtained by means of pieces of metal encased in ebonite, which are flush with the bottom of the groove and in communication with the pole wires. Once the apparatus regulated—and this regulating cannot be otherwise than a delicate matter—it is coated with varnish to keep the carbon paste in the groove. Lastly, the apparatus is protected by a brass casing. These appliances are of incontestable utility, and are recommended by their cheapness, so that it is to be hoped that their use will become general in laboratories."

THE "GREAT EASTERN."—Instead of going to Gibraltar as a coal hulk, the "Great Eastern" is bound to the mouth of the Mississippi, to be used as a floating hotel. She will prove the attraction at New Orleans, and be an exhibition in herself. The fitting out of the "Leviathan" has commenced in real earnest. As far as possible, the work has been given to local contractors. It is estimated that it will take about six weeks to get her ready for her trip to the New World. Like Milford Haven, in which she is now peacefully anchored, her career so far has been anything but bright. But cheerful for twelve months (should she reach her destination in safety) it certainly will be. There will not only be joyous days for her, but also "revelry by night," with the "Stars and Stripes," instead of the "Union Jack," floating at her masthead. Milford Haven will, however, miss her—for over eight years their fates have been linked together.

THE NEW ORIENTAL BANK CORPORATION AND THE EASTERN TELEGRAPH COMPANY.—In the course of his remarks in addressing the statutory meeting of the shareholders of the New Oriental Bank Corporation, held on the 17th inst., Mr. W. W. Cargill (the chairman) spoke of the difficulties which had been met with in the formation of the bank through want of money, owing to the company not having been established through the assistance of any professional promoter. Mr. Rohde, however, had been fortunate in obtaining the aid and sympathy of many friends. But the most notable assistance had been that afforded by the chairman and the managing director, Mr. Pender and Sir James Anderson, of the Eastern Telegraph Company, who with the greatest kindness undertook to send all the telegraph messages required to and from the East in order to bring together the sentiments of people interested in the reconstruction of the bank. But for this assistance he did not see that Mr. Rohde could have carried out what he had done.

MORE BALLOON STEERING.—On 8th November two more ascents were made by Capt. Renard from Meudon, near Paris, with most successful results. About noon he rose from the departure lawn, and when clear of the surrounding heights set the propeller to work, which gradually increased the speed of the balloon. Meudon Viaduct was soon reached, and the Seine crossed below the Billancourt Bridge, when the balloon

Digitized by Google

made for Longchamp, and came to a full stop a few hundred metres from the river. The screw was then stopped, and the speed due to the air current found to be eight kilometres, or five miles an hour. After five minutes' stoppage the screw was again started. The balloon described a half-circle, and went straight for the starting point, which was made with the greatest precision, after a 45 minutes' voyage, during which a speed of 23 kilometres, or 14 miles had been attained. After a rest of two hours the balloon was sent up again, and caused to make several evolutions in the neighbourhood of Chalais, turning to the right and left, stopping, starting again, and finally returning to the place whence it had departed.

Static Electricity for Children.—Our contemporary, *Kosmos*, gives the following directions for amusing the rising generation with electrical demonstrations which are quite as striking as rubbing a cat's back the wrong way. Heat a sheet of paper and pass it quickly between your trousers and the sleeve of your coat, or between the sleeve of the coat under the arm-pit, or even between the fingers, though this does not succeed so well. The paper will have become charged with electricity; but, as it is a bad conductor, the current accumulated on the surface will remain there. On holding the sheet by one corner and bringing the finger to the side, in a dark room, sparks will be seen, accompanied by a slight cracking noise. On placing gold leaf between two sheets of paper and charging them with electricity as before, the action of drawing the point of a pencil over the surface will cause a luminous line to appear in the dark. If two bands of paper about 8in. wide be placed together and rubbed only once in the manner above described, they will become so highly charged as to repel each other without it being possible to bring them together.

Conductivity of Saline Solutions.—Early this year M. Bouty communicated to the Paris *Académie* some general laws which he propounded as to the electrical conductibility of weak saline solutions. Professor Giuseppe Vicentini, observing their disagreement with the observations of Dr. Lenz, undertook a series of investigations by way of arriving at the truth; and the following are his conclusions, as recorded by the *Rivista Sientifico Industriale*:—(1) The electric conductivity of solutions of salts in water increases in direct ratio to their concentration, and this fact is true even for very diluted solutions; (2) The various salts experimented upon, even in very weak solutions and for the same degree of dilution, do not appear to have the same molecular conductibility; (3) The influence of the temperature on the electric conductivity of the solution is precisely the same for very diluted solutions of the various salts, and increases with the temperature; (4) In representing the electric conductibility of a very diluted saline solution at the temperature t, by the formula $C^t = C_0 (1 + \alpha + \beta t^2)$ the value of α approaches the value of the analogous coefficient, which gives the coefficient of friction of the water for a given temperature, while the coefficient β, much smaller than the coefficient of friction of the water, tends to increase with the weakness of the solution.

The Weston Lamp.—Since about the beginning of the present year the carbons of the Weston incandescent lamps have been made from gun cotton, by the following process:—The gun cotton, after being dissolved, is moulded into cakes, which are then cut into thin sheets. These are soaked in sulphide of ammonia, which removes the nitryl and converts the structure into pure cellulose. The sheets are then rolled to the thickness desired for the filaments, which are then cut out by dies in the zigzag form adopted for the standard (16-candle power) lamps, which form is claimed to give a more uniform illumination at all angles than the plain loop. The threads for the large (125 candle-power) lamps, however, are cut straight. The filaments are then packed in plumbago and baked several hours in a furnace. Having thus been carbonised they are treated by the Maxim process for correcting irregularities in the size and resistance. This, briefly, is as follows:—The filament is held by temporary clamps in circuit in a vacuum into which a little hydro-carbon vapour has been introduced. When the current is passed the hot filament decomposes the hydro-carbon vapour, and deposits the carbon on itself. Those places which are smallest and have the most resistance become the hottest, and thus receive the largest deposit, so that the resistance is made uniform throughout.—*Sanitary Engineer.*

Electric Light in Mines.—Three years ago, Siemens and Halske, of Berlin, installed two 3,000-candle arc lamps in an open working, 2,000ft. long, 1,000ft. wide, and over 300ft. deep, at the Mechernich mines, Rhenish Prussia, in which 300 men and twenty horses are constantly employed. The lamps were placed sufficiently high, above the steps in which the mine is worked, to be out of reach of stones projected by blasting; and the light is thrown down on the workings by powerful reflectors. As any interruption, even for short periods, such as those occupied in renewing the lamp carbons, would be dangerous, the whole plant is double, each lamp receiving its current from a D_2 dynamo. No hitch whatever has occurred; and the safety of the mines has been decidedly increased, while the cost shows a saving of about 4d. an hour in favour of the electric light. This satisfactory result obtained in the open workings led the company to introduce the light in the subterranean galleries, which are constantly widened out till they become 90ft. wide and 70ft. high, the length being sometimes 300ft. At first, arc lamps of 1,000 to 3,000 candle-power were used, with the positive carbon in the lower holder; but the light did not sufficiently penetrate the white smoke generated by the shot. As the smoke settles in ten minutes, however, it was thought advisable to wait this short space of time and use lamps of 350 candle-power, which proved thoroughly efficient. Ten of these are used with about 10,000ft. of lead cable, which permits of the lamps being removed when a shot is to be fired.

The Vulcanisation of Rubber.—For vulcanising india rubber there is generally employed a bath of sulphur and steam under pressure. According to the *Chronique Industrielle*, Messrs. De la Tour du Breuil Brothers have conceived the idea of substituting a concentrated solution of calcium chloride capable of furnishing a constant temperature of from 150 to 160 degrees. The advantages of this substitution are very important, and may be summed up as follows:—There is no modification required in the present apparatus existing in factories. The iron plate vats, not being exposed to burning, last much longer. The capital invested in the bath is insignificant compared with that required by the sulphur bath. Sulphur, in fact, costs in Paris about 200 francs per ton, while calcium chloride is but 80 francs. The daily consumption of the chloride, when the bath has once been prepared, is almost nothing, since this salt is fixed and indecomposable, while with sulphur there is a continual consumption, on account of its volatilisation and accidental combustion. As a consequence of the suppression of the vapours of sulphur and sulphurous acid in the works, the manufacture has no bad influence upon the health of the workmen. There is no danger of fire, and consequently the

Digitized by Google

insurance rates are lower. The apparatus lasts longer, since the iron employed for locking the moulds no longer has sulphur to combine with and make it brittle. The consumption of fuel is greatly reduced (say about two-thirds), since the bath has a powerful calorific capacity, and the vats may be heated by an open fire. Finally, as the boiling is much gentler and more regular, it gives products of superior quality, and little or no waste, on account of the facility that exists of always keeping the bath at a temperature of between 150 and 155deg.

THE THUNDERSTORMS OF 1884.—The November issue of *Symons's Meteorological Magazine* deals fully with the year's thunderstorms. The summary is as follows:—"We are well aware that in these days it is not easy to induce persons to read through a long list of casualties such as we have at last concluded, but we can assure our readers that there are many cases extremely interesting and instructive. As our Government (unlike those of France and Germany) does nothing towards the registration of damage by lightning, we have made an effort in that direction this year. But it is utterly unreasonable to expect such work to be done by private effort, and we are certain that our list is very imperfect; as regards minor accidents, injury to trees, to sheep, and to cattle, it is probably less than half the truth. Doubtless further information might have been obtained from the Agricultural Insurance Companies; but the compilation of such a list is not our duty, and it ought to be done officially, as in other countries. However, we have done what time allowed; and the results are important, and probably unexpected. The final totals are large; 35 men killed and 91 injured is a sad beginning to the list, and one to which no money value can be assigned. But as regards the other items, we have tried to form an approximate estimate, a very wild one we admit, but one in which we have tried to keep the amounts low, and in which probably errors will neutralise each other. Leaving the people out of the calculation entirely, the damage recorded comes to nearly £10,000, and had all damage been reported, and proper records kept of the values, we have no doubt that it would be nearer £30,000 than £10,000." The remaining totals show 44 horses killed and 8 injured, 181 cattle killed and 14 injured, 239 sheep killed, also two dogs and three pigs. The trees struck numbered 82, while 14 stacks were destroyed and 18 others struck; also 20 churches, 112 houses, 10 cottages, 21 barns, 42 chimneys, and 11 factories more or less injured.

SOCIETY OF ARTS.—The first meeting of the 131st session of this society was held on Wednesday night at the hall in the Adelphi. The audience included Sir Frederick Abel, F.R.S., chairman of council, who presided; Lord Alfred Churchill; Sir Philip Cunliffe-Owen, C.B.; Sir Frederick Bramwell, F.R.S.; Sir Robert Rawlinson, C.B.; Captain Douglas Galton, C.B.; Professor Dewar; Mr. W. H. Preece, F.R.S., and Mr. J. M. Maclean. Sir Frederick Abel, in referring to the death of Sir William Siemens, went on to speak of the topics dealt with in his unfinished address, with which, had its writer lived, the last year's work of the society would have been begun. Prominent among these was the final settlement, by the Electrical Congress which met in Paris last April, of the standard of electrical resistance to be adopted for international use, as well as of other important matters relating to electrical units of measurement. The results obtained in different countries by applications of the various means of electrical measurement, which have already attained a high degree of perfection, are now expressed in what may be termed a universal language, the few words of which serve at the same time as monuments to the memory of some of the most illustrious pioneers in electrical science—Volta, Ohm, Ampère, Coulomb, Faraday, and Watt, the employment of the last name being a suggestion, now adopted, by Siemens himself. That electric lighting was really progessing in this country was shown by a reference to the successful work effected at the Health Exhibition, some statistics being given of the amount of power employed, its result in the light produced, and other similar points. As regards the experience gained from this extensive installation, Sir Frederick Abel believed it proved, as regards lamps, that there are now eight or nine really trustworthy makers, and as regards dynamo machines, that the occasional failures have been due quite as much to the mechanical accessories as to the machines themselves. Looking at the results of the year's experience, not only at South Kensington, but elsewhere, it appeared that while the practical difficulties attending the distribution of power for lighting up an extensive populous district from a large central station are much what they were when Sir William Siemens explained their nature two years ago, the working of small central stations has now for some time past been efficiently carried on in many parts of the kingdom. Further than this, it has been demonstrated that the working and proper control of an entirely self-contained electric light installation is within the powers of a domestic establishment, and that electricity could much surpass in efficiency, and perhaps cope in point of economy, with our usual domestic illuminating agents and appliances. A tendency to exaggerate the danger attending the introduction of electric lighting in houses, and the working of some of the powerful dynamo machines used in connection with large installations, has been encouraged by the occurrence of a few cases of fire in buildings where the fittings have not been properly executed, and of a few fatal accidents resulting from the employment of inexperienced or heedless men in working machines which engender currents of extremely high electromotive force. Accidents from the first cause can be effectually guarded against by careful attention; and the probabilities of fire being originated by electric light fittings in houses are certainly small as compared with actual casualties attending the use of gas, petroleum lamps, and other illuminants. With respect to the second class of accidents, it had been pointed out that if the electromotive force circulated in conducting wires does not exceed 600 volts neither danger to life nor injury to health can result from the careless handling of conductors or parts of a machine, and that, so long as the size of conductors is in ample proportion to the work to be done, no necessity arises for exceeding the safe limits of what may be termed electrical pressure. As regards the future of electric lighting, especially incandescent lighting, Sir Frederick spoke hopefully, quoting authorities to show that considerable improvement might be expected in the construction of glow lamps, possibly even improvements which would reduce the cost of the light to one-fifth the present amount. The other practical applications of electricity and the progress made in them were next passed in review; the advances in the development of electrical railways in Austria, Germany, and the United States, as well as in these islands, and the possibility of using electrical power more extensively than has yet been done for propulsion on water were described; and this part of Sir Frederick's address concluded with an approving notice of the system of electric transmission of power to which its inventor, Professor Fleeming Jenkin, has given the name of "Telpherage." Sir Frederick Abel also spoke approvingly of the efforts made by Captains Renard and Krebs, the two French officers attached to the Military Balloon Establishment at Meudon, whose recent trips have attracted so much public attention; still, but little real progress has been made.

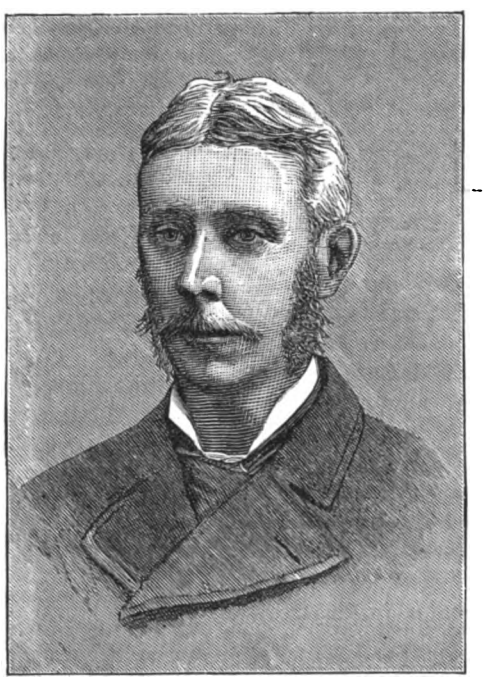
ROOKES EVELYN BELL CROMPTON.

CROMPTON, ROOKES EVELYN BELL: Born near Thirsk in Yorkshire 1845, educated at Elstree Hill School, Harrow School, and in Paris; entered the army, and appointed to the Rifle Brigade in 1863. Served with his regiment in India until 1869; from 1869 to 1875, held an appointment under the Department of Public Works as engineer in charge of the Government steam train. During this time he carried out for the Indian Government a long series of experiments on traction by steam on the roads of India. In 1876, left the service and became a partner in the firm of T. H. P. Dennis and Co., of Chelmsford. A year later he became engineer in chief of the Stanton Iron Works Company. For this company he designed and superintended the construction of their foundry, which is one of the largest in the United Kingdom. Shortly after the completion of the foundry, necessity for working continuously day and night led him to study the possibility of adopting the electric light, which at that date, 1877, was a novelty in this country. Early in 1878 he purchased for the company a plant of two Gramme machines and two Serrin lamps. The following year he commenced the manufacture of electric light apparatus in a small building attached to Messrs. Dennis's works at Chelmsford. His first inventions related to burning arc lamps in partial vacua, and to the improvements in the arc lamps themselves. These improvements were exhibited at the Agricultural Show in Kilburn in 1878 and at the exhibition of electric light apparatus held at the Albert Hall in 1879. The lamps were made for practical use, and a considerable sale was soon obtained for them. In 1879, through the instrumentality of Mr. Brown, the well known tramway engineer of Winterthur in Switzerland, Mr. Crompton made the acquaintance of Mr. Bürgin, of Basle, who had just brought out his dynamo electric machine. Mr. Crompton at once laid out works on a considerable scale at Chelmsford for the construction of this machine. In conjunction with Mr. Bürgin he introduced considerable improvements, and converted the original machine, which was only capable of driving one arc lamp, into one giving a current of higher E.M.F., and capable of driving four or five lights in series. The lighting at Queen-street Station, Glasgow, King's Cross Station, London, the Bricklayers' Arms, London, and the Mansion House, are instances of works successfully undertaken about this period. In 1879 Mr. Swan invited Mr. Crompton to Newcastle to see the incandescent lamp tried on a commercial scale, and the question of manufacturing dynamo machines suitable for working the incandescent system was seen to be of the greatest importance. In 1881 Mr. Crompton exhibited largely at the Exposition International d'Electricité at Paris, and obtained one of the few gold medals awarded to English firms; and in the following year he again exhibited at the Crystal Palace and obtained another gold medal. Shortly after this he commenced the investigation of the subject of making self-regulating dynamo machines, and with the assistance of Mr. Kapp, who had become his works manager, he brought out the now well-known system of winding the field magnets of dynamos with series in addition to shunt coils. To machines thus wound he gave the name of "compound" machines, and this name has been generally adopted by makers and users of such dynamos. The invention of compound winding has been claimed for others, but it remains a fact that the first dynamo machines made practically self-regulating by the compound principle were those made and set to work by Messrs. Crompton for Mr. Coope at Berechurch Hall, near Colchester, in the spring of 1882.



Believing that the best method of supplying the electric light to the public in their private houses would be in the nature of a co-operative supply, similar to that of gas and water, Mr. Crompton took an active part in the enlargement of the original Swan Company into the Swan United Company, hoping thereby to form a powerful corporation for the supply of electric lighting to large districts in London. He also devoted a great deal of time and attention to the Electric Lighting Act, and subseqnently to obtaining from the Board of Trade provisional orders for the Swan United Company, and for other companies, for lighting various parts of London, Birmingham, &c. He prepared most of the technical information for Mr. Moulton, enabling that gentleman to draft the provisional orders which were afterwards adopted by the Board of Trade with but slight modification as their model provisional order. He protested in the strongest terms against the introduction of the 21 years' purchase clause, which has been considered so fatal to the electric light companies. Mr. Crompton has never sold any of his patents, although at the time of the electric light mania he had many tempting offers to do so. Seeing that over speculation was likely to retard for many years the accomplishment of the house-to-house electric lighting on a large scale, he again turned his attention to the laying down of isolated installations and to the general improvement of electric light machinery, and with the result that during the last three years he has, either alone or in conjunction with other co-workers, brought out a long series of inventions in arc lighting, electric conductors, street mains, accumulators, dynamo electric machinery, and electric governor apparatus for steam engines and other prime movers. During the last two years he has been engaged in perfecting a new type of dynamo machine, which has given remarkable results, far exceeding those he was able to obtain from the Bürgin or any of the contemporary machines. The development of his works at Chelmsford has gone on hand in hand with the development of electric lighting, although, as we have seen above, these works were only commenced in 1878. In this year, 1884, they cover several acres of ground, and employ over 300 men.

We believe that Mr. Crompton, in conjunction with Mr. Norman Lockyer, F.R.S., investigated spectroscopically and otherwise the varying conditions of the electric arc from the point of contact to the complete breaking of the circuit; but no detailed results of this investigation have as yet been published. He was also greatly interested in the experiments which proved the lighting of mines by electricity practicable.

It is sometimes unfortunate that the greater portion of periodical technical literature is anonymous, so that but few people know the authors to whom they are indebted for valuable information. Mr. Crompton has greatly enriched technical literature either by writing or otherwise communicating information, and has contributed several papers to the *Transactions* of learned societies, principally the Society of Telegraph Engineers, of which society he is a member of the council. So far as we know, only a small work on electric lighting has been published independently, although some of the papers have been republished by Messrs. Spon, of Charing Cross.

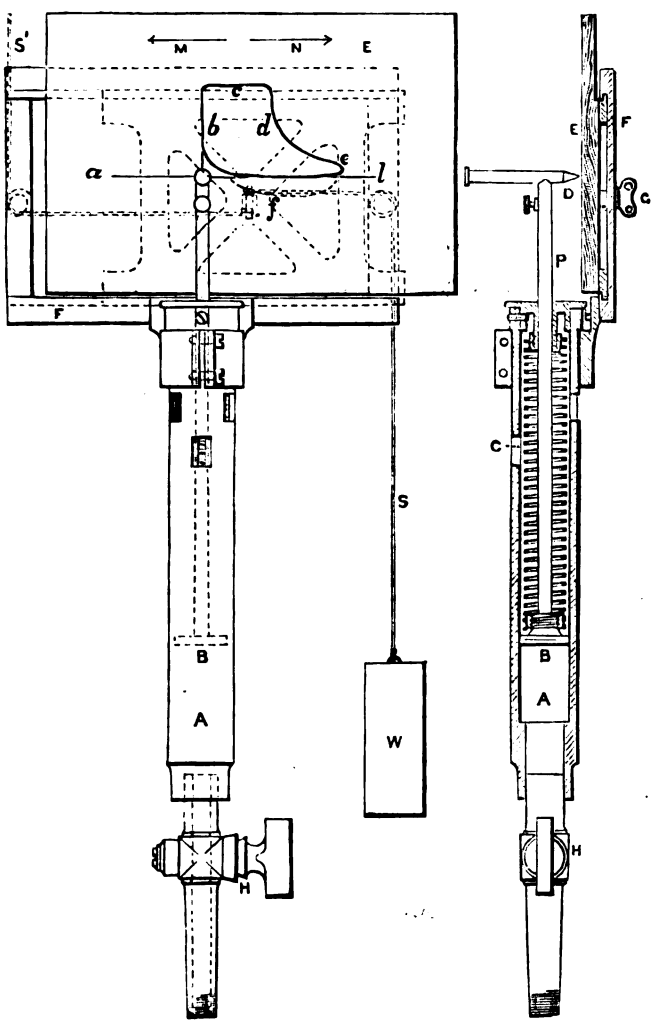
THE STEAM ENGINE INDICATOR.—II.

BY AMICE.

Watt's indicator should be here described, as it may be taken as illustrating the simplest form of the instrument, and our younger readers will be assisted by reference to its construction. Several of these indicators are still in existence, and the accompanying engravings from the *Proceedings* of the Institute of Mechanical Engineers, 1883, is made from one of these.

Although, generally speaking, and as concerns practical work, the indicator as made by Watt is of little more than historic interest, it is of considerable educational value, because a knowledge of this, as the simplest form of indicator, will make the principle of the instrument more easy of acquirement than if described by reference to its modern representative, while an explanation of its defects will make clear the reasons for the steps in the development of those now most used. It will therefore be described here at length, not because of its historic interest, but as being necessary to our purpose.

FIG. 4. FIG. 5.



Watt's Indicator.

From our engravings, Figs. 4 and 5, it will be seen that a cylinder, A, is fitted with a piston, B. To this is attached a piston rod, P, which at its upper end carries a pencil, D. The piston B moves upward in the cylinder, under the action of steam admitted by the cock H. Above the piston is a spring, C, the strength of which is known; that is to say, the number of pounds which is necessary to compress it through a given range is ascertained before it is used in the indicator. Suppose, for instance, it takes a weight of 10lb. to compress the spring one inch; then when it is placed in the indicator it will require 10lb. to do the same compression, and if the cylinder be one inch in diameter, and consequently 0·7854″ sectional area, it will require a steam pressure of $\frac{10}{0{\cdot}7854}$, or 12·719lb. per square inch to compress the spring and raise the piston one inch. In practice, however, the springs are made of such strength that they will compress through a range of one inch with a pressure represented by a convenient number, and in the above case the spring would be of such strength that with a steam pressure of 10lb. per square inch it would compress one inch, and therefore with a load of $10 \times 0{\cdot}7854 = 7{\cdot}854$lb.

Mounted with slides in the frame F, as seen in Fig. 5, is a board, E, to which is attached the piece G. Fastened to G is one piece of string, S, running over a small pulley, and carrying the weight W, and another piece of string, S′, running over another pulley and attached to some part of the engine which has a reciprocating movement synchronous with that of the piston of the engine. The board E is thus pulled in the direction M by the string attached to some part of the engine, and as that part returns with the return stroke of the engine piston, the weight W pulls the board back in the direction N. The weight W thus acts in pulling the board E in one direction, and also prevents any slack in its movement. The cock H being screwed into one end of the steam engine cylinder, the cylinder A of the indicator receives steam at the same time as the engine cylinder, and at the same time the board E is put into motion by the engine. A piece of paper is attached to the board E, and the board allowed to be moved by the engine before steam is admitted to the indicator cylinder A. The pencil being lightly pressed against the board, the line *a l* will be made, and will represent the pressure of the atmosphere. It will now be seen that the engine piston being at the end of its stroke, and steam being admitted to the cylinder, it will also be admitted to A, and the pencil D will instantly rise and trace the line *b*, which will have a height according to the steam pressure. The engine piston being now in motion, the board E is pulled in the direction M, and the horizontal line *c* is traced. This line will be at a height above the line *a l*, which will represent the maximum pressure per square inch in the steam engine cylinder, and if the ports in that cylinder are of sufficient size and the movement of the slide valve sufficiently rapid, this pressure will be maintained in the cylinder until near the point at which the entrance of steam into the cylinder is cut off by the slide valve. From that point the pressure of the steam falls in the cylinder, as shown by the curved line *d*, this line being the expansion curve, or the line which shows the pressure existing in the cylinder at any part of the stroke of the piston during the expansion of the volume of steam admitted up to the point of cut off. At *e* the exhaust port is opened, and steam instantly rushes into the atmosphere, or into the condenser, if the engine is fitted with the latter, and the pressure falls correspondingly, and the pencil with it. At the same time the return stroke of the engine commences, and the weight W pulls the board E back as that stroke is made, and the pencil D traces the line, completing the diagram, this line being nearly parallel with and nearly coincident with the atmospheric line *a l*, if the engine is non-condensing. If the engine is fitted with a condenser the pressure falls below the atmospheric pressure; in other words, a vacuum more or less complete is made by the condensation of the steam, and the line *f* is traced. In this case the pressure against the engine piston is represented by the distance between the line *f* and *c d*, instead of between the line *a l* and *c d*. To the form in detail of the diagram we shall recur hereafter.

The steam engines made by Watt were all very slow speed engines, and a low pressure of steam was used. Under these conditions a spring of rather long range and with the pencil attached direct could be used. The return motion of the indicator paper or card could also be effected by a weight, as shown. With the use of high pressures and high speeds, however, it became necessary to alter these parts. In the first place, board E of the Watt indicator was large and inconvenient, and the weighted string acted in a jerky manner, making the movement of the board unsteady, especially in the direction N. To overcome these objections, the indicator known as M'Naught's was made. In this the range

Digitized by Google

of movement of the pencil was, like Watt's, the same as that of the compression of the spring, but the board E was replaced by a vertical hollow cylinder turning upon a vertical axis. This cylinder contains a spring, which takes the place of the weight W in Watt's indicator, and the paper or card being placed upon it, the pencil traces the diagram exactly as on the flat board. This improvement did not remove the defect due to the use of a long range spring and of a pencil attached thereto, the effect of which was that with high pressure steam and quick running engines the instantaneous compression of the spring was followed by a series of elastic oscillations, sometimes of considerable range, aggravated by the inertia of motion of the piston and attached parts, and causing the pencil to trace an irregular line, which reduced the value of the diagram as an indication of the behaviour of the steam in the cylinder. The pencil would trace a line as

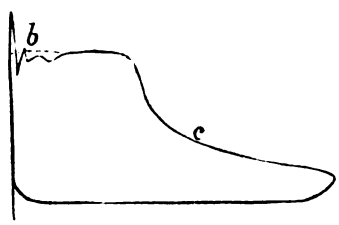


FIG. 6.

shown at *b* (Fig. 6), making it difficult to obtain the mean pressure line, which would probably be as indicated by the dotted line. In very high speed engines the whole of the line from *b* to *c* (Fig. 6) was of an irregular character, giving evidence of tremulous movements due to the indicator itself, and not at all due to the engine. To remedy these defects Mr. C. B. Richards, an engineer living at Hartford, Connecticut, designed the indicator known by his name. McNaught's indicator is only to a small extent employed now, other forms are much more used, the Richards indicator being still the best known.

With a description of this we shall commence our next article.

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 8.)

Three Similar Coils and Cores.

With the same notation, the equation of E.M.F. in the circuit is, by an obvious extension of (102),

$$0 = H_1 + \frac{L-3M}{R}\dot{H} + s(H'_1 + H'_2 + H'_3) \quad . \quad . \quad (110)$$

and, if

$$AJ_0(nr_1)e^{Dt}, \quad BJ_0(nr_2)e^{Dt}, \quad CJ_0(nr_3)e^{Dt}$$

be a normal system, continuity of current in the circuit requires that

$$AJ_0(nc) = BJ_0(nc) = CJ_0(nc);$$

giving $A = B = C$, when $J_0(nc)$ does not vanish. Corresponding to (105) we have the determinantal equation

$$\{J_0(nc)\}^2 \left\{ (1 + \frac{L-3M}{R}D)J_0(nc) - 3snJ_1(nc) \right\} . \quad . \quad (111)$$

with two sets of roots, as in the last case, the first set corresponding to circuit broken, the second set to a single coil with circuit closed.

Regarding the ratios A:B:C when the roots are those of the first set, we may be guided by physical considerations. Decompose the initial magnetic forces H_1, H_2, H_3 into

$$\begin{aligned} H_1 &= \tfrac{1}{3}(H_1 + H_2 + H_3) + \tfrac{1}{3}(H_1 - H_2) + \tfrac{1}{3}(H_1 - H_3), \\ H_2 &= \quad \text{ditto} \quad + \tfrac{1}{3}(H_2 - H_1) + \tfrac{1}{3}(H_2 - H_3), \\ H_3 &= \quad \text{ditto} \quad + \tfrac{1}{3}(H_3 - H_1) + \tfrac{1}{3}(H_3 - H_2). \end{aligned}$$

The portion $\frac{1}{3}\Sigma H$ common to all three obviously requires the use of the second set of roots. The other six terms cancel one another as regards E.M.F. in the coil circuit. Thus, $\frac{1}{3}(H_1 - H_2)$ in first core and $\frac{1}{3}(H_2 - H_1)$ in the second cancel, and similarly for the other two pairs. They therefore require us to use the first set of roots only. We may write the decomposition thus,

$$\left.\begin{aligned} H_1 &= \tfrac{1}{3}\Sigma H + (H_1 - \tfrac{1}{3}\Sigma H) \\ H_2 &= \tfrac{1}{3}\Sigma H + (H_2 - \tfrac{1}{3}\Sigma H) \\ H_3 &= \tfrac{1}{3}\Sigma H + (H_3 - \tfrac{1}{3}\Sigma H) \end{aligned}\right\} \quad . \quad . \quad . \quad (112)$$

Consequently the solution for the three cores is to be found in a similar manner to before. Starting with any arbitrary distributions, substitute for them, first a distribution $\frac{1}{3}\Sigma H$ in every core, and let them subside according to the second set of roots, adding their effects in the coil circuit. And let simultaneously the complementary distributions $H_1 - \frac{1}{3}\Sigma H$, &c., subside, each in its own core independently, according to the first system. The resultants will give the actual state of things. The curves of axial subsidence, when the initial distributions are constant, may be found from curve h_0h_0 (Fig. 3), and either H_0H_0 or a similar one, by constructing three new curves whose ordinates are made up of those of H_0H_0 and h_0h_0 taken in the proper proportions expressed in (112).

Any Number of Coils.

The extension to any number m of equal coils, with equal cores, in sequence, is plain. The determinantal equation is

$$\left\{ J_0(nc) \right\}^{m-1} \left\{ \left(1 + \frac{L-mM}{R}D\right)J_0(nc) - msnJ_1(nc) \right\} = 0 \quad (113),$$

with the two sets of roots as before, the repetition of the roots of $J_0(nc) = 0$ only affecting the ratios of the constants A, B, C, &c., in a normal system. The decomposition is

$$\left.\begin{aligned} H_1 &= \frac{1}{m}\Sigma H + (H_1 - \frac{1}{m}\Sigma H) \\ &\cdots\cdots\cdots \\ H_m &= \frac{1}{m}\Sigma H + (H_m - \frac{1}{m}\Sigma H) \end{aligned}\right\} \quad . \quad . \quad (114).$$

The mean distribution $\frac{1}{m}\Sigma H$ is what makes the coil current. This distribution must be imagined to exist in all the cores, each with its proper complementary distribution; the mean distribution to subside one way, using the second set of roots, the complementary to subside as if the coil circuit were interrupted. It is unnecessary to write out the developments, such being merely repetitions of the solutions in Examples 1 and 2 or 3. But the general case of any number of dissimilar coils and cores joined in sequence, of which the above is a special case, does not admit of the reduction to two simple solutions, so its theory will form the subject of a later section.

Equal Coils, with Cores, in Parallel.

Two coils in parallel being the same as two in sequence, nothing more need be said about it. We may consider the theory of three coils in parallel, and its natural extension to any number. Let P and Q be the common terminals of the three branch conductors containing the coils; every branch to have the same resistance and self induction, and to contain a coil with a core, the three coils being alike, and also the three cores. Let Γ_1, Γ_2, Γ_3 be the three currents, reckoned from P to Q, and V the fall of potential from P to Q. This being the same for the three branches, we have the equation of E.M.F.

$$V = R\Gamma_1 + (L-M)\dot{\Gamma}_1 + S\Gamma'_1 \quad . \quad . \quad . \quad (115)$$

in the first branch, and two similar equations with Γ_2 and Γ_3 written for Γ_1. Here $S = M\rho/2\pi\mu c$, and L and M are the coefficient of self induction of a branch, and that part of it due to the core. We have also the equation of continuity

$$\Gamma_1 + \Gamma_2 + \Gamma_3 = 0; \quad . \quad . \quad . \quad . \quad . \quad (116),$$

the sum of the currents meeting at P or at Q being zero.

A normal system of magnetic force in the cores being

$$A_1J_0(nr_1)e^{Dt}, \qquad A_2J_0(nr_2)e^{Dt}, \qquad A_3J_0(nr_3)e^{Dt},$$

with the currents in the coils

$$A_1J_0(nc)e^{Dt}/4\pi N, \qquad A_2J_0(nc)e^{Dt}/4\pi N, \quad A_3J_0(nc)e^{Dt}/4\pi N$$

to correspond, substitution of the latter for Γ_1, Γ_2, Γ_3 in (115)

Digitized by Google

and (116) gives, by eliminating V and the A's, the determinantal equation

$$J_0(nc)[\{R+(L-M)D\}J_0(nc)-snJ_1(nc)]^2=0, \quad . \quad (117);$$

or say $xy^2=0$; giving the two sets of roots belonging to $x=0$, and $y=0$. The equation $x=0$ means that there is no current in any of the coils, and $y=0$ that the terminals P and Q are at the same potential, as if the three branches were put on short circuit.

There being two manners of subsidence of initially given distributions of magnetic force, which we shall refer to here and later as the first manner (no coil current or circuit broken), and the second manner (branch containing a coil on short circuit), it only remains to properly effect the division of the given distributions into two distributions, such that one will give no current in the coils, and the other will give currents subject to the condition of continuity (116). Now, if we start with a distribution H_1 in the first core, and none in the others, and substitute the distributions $\frac{1}{3}H_1$, $\frac{1}{3}H_1$, $\frac{1}{3}H_1$ in the first, second, and third cores, these will subside in the first manner, owing to the balanced E.M.F.'s; whilst the distributions $\frac{2}{3}H_1$, $-\frac{1}{3}H_1$, $-\frac{1}{3}H_1$, which with the former make up the given real distributions H_1, 0, 0, will give currents complying with (116); *i.e.*, a current in the first branch from P to Q dividing equally between the second and third branches, in which it is directed from Q to P. This is the proper division so far as H_1 is concerned, and those for H_2 and H_3 may be similarly constructed. Putting all together, we find the proper division when H_1, H_2, H_3 are all finite, is

$$\left.\begin{aligned} H_1&=\tfrac{1}{3}\Sigma H+(H_1-\tfrac{1}{3}\Sigma H),\\ H_2&=\tfrac{1}{3}\Sigma H+(H_2-\tfrac{1}{3}\Sigma H),\\ H_3&=\tfrac{1}{3}\Sigma H+(H_3-\tfrac{1}{3}\Sigma H),\end{aligned}\right\} \quad . \quad . \quad . \quad (118)$$

the common mean distribution $\frac{1}{3}\Sigma H$ in each core to subside in the first manner, and the remainders in the second manner, furnishing the coil currents.

Contrast with the case of three coils in sequence, the division being represented in equations (112). These are the same as (118), but whereas in the latter case the mean distribution furnishes no coil current, in the former it is the mean distribution that supplies the coil current.

The extension to any number m of equal coils in sequence may be shortly stated. The determinantal equation is

$$xy^{m-1}=0, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (119)$$

which may be compared with (113), the corresponding equation when the coils are in sequence, which, written similarly to (119), is $yx^{m-1}=0$.

The proper division of the initially given distributions of magnetic force in the cores is given by equations (114), only noting that the mean distribution $\frac{1}{m}\Sigma H$ must now subside in the first manner, instead of, as in the case to which (114) relates, in the second manner, with the corresponding change as regards the complementary distributions.

(TO BE CONTINUED.)

LITERATURE.

Arithmetical Physics. Part IA. Acoustics, Light and Heat. Part IIA. Magnetism and Electricity. By C. J. WOODWARD, B.Sc. [London: Simpkin, Marshall, and Co.]

There is nothing like being a teacher in order to explain what you really know of a subject, and how to put that subject to a learner. We do not refer to teachers who are merely teachers for so many pounds a year, and who are as little related to real teachers as a cat is to a fire-shovel. Teachers of the physical sciences necessarily require a large number of exercises or questions to be put to the pupils, either for clinching the moral of a tale or examinational purposes. It is an immense labour to have to make these questions for oneself, yet we should not advocate the entire dependence upon any collection. Mix them. Then, again, special courses are held preparatory to various examinations in which special points arise requiring special questions. In these books Mr. Woodward has had in view the preparation for the London Matriculation and the First Stage of the Science Department. The books are admirable of their kind. They provide a *memoria technica* of the principal laws and rules for the solving of problems, interspersed with questions fully solved, followed by a large collection of examination questions, the whole forming a valuable adjunct to the science teachers' apparatus.

Exercises in Electrical and Magnetic Measurement. By R. E. DAY, M.A. New Edition. [Longmans, Green, and Co.].

It is almost two years ago—*vide The Electrician*, Vol. X., p. 70—that we had occasion to notice the issue of a little work, by Mr. Day, entitled "Electric Light Arithmetic." We have used that work a good deal, and found it very useful. It had its defects, however, in that it was too small, and contained a number of misprints. The old book contained some eighty pages, the new edition contains more than one hundred and eighty, and in addition the page is larger. These facts show that the subject matter has been largely extended. The plan adopted is to deal with the subject in sections, there being no less than twenty sections. It will be sufficient to analyse one of these. Take, then, the first, on "Electrostatics." The section commences by giving a question bringing out the fundamental formula $F=\frac{q_1\times q_2}{d^2}$, where F = force, q_1 q_2 = quantities, d = distance. When unit quantities and unit distances are taken, the result F is in dynes, or unit force. The formula is followed by specimen solutions and questions for the student to solve. Density and charge are similarly treated. Thus we have formulæ followed by solved and unsolved questions upon the formulæ. Differing from the ordinary books of questions, which are generally compiled for examination purposes, these formulæ and questions are such as come daily before the worker in his practice. Here the practical man will find practical questions on "heating effects," "shunts," derived circuits generally, resistance, conductivity, "magnetic action," and so on, enabling him not only to go to work by the rule of thumb method, but in a short time to work with the exactitude which, in electrical work, contributes so much to success. We think a study of the book and the solutions of the questions will prove beneficial to every student.

PORTABLE STORAGE BATTERY FOR MINES.—At the last meeting of the Engineers' Club of Philadelphia, Mr. C. Henry Roney showed a portable storage battery for mining and exploring purposes, with small incandescent lamps, illustrating his remarks with blackboard sketches. The battery shown was a modification of Planté's, devised by Dr. E. T. Starr, of Philadelphia, the electrodes consisting of V-shaped plates of sheet lead arranged over each other, the convexity downward, with a slight interval between them, their ends attached to a lead frame by "burned" joints, the interstices between the plates being filled with finely divided metallic lead, exposing a large surface to oxidation and reduction when subjected to dynamic electric or voltaic energy, and, in turn, giving off a large percentage of the stored energy to incandescent lamps placed in the circuit. The battery shown measured 3¼in. long, 2¾in. high, and ¾in. thick, and would maintain a small two-candle incandescent lamp at incandescence for about one hour. A battery sufficiently large to run an eight-candle lamp for ten or twelve hours would not be too large or heavy to carry conveniently for mine or other underground exploration.

ELECTROLYTIC REDUCTION OF GOLD.—Henry R. Cassel, of New York, has invented a process by which 95 per cent. of the gold contained in the most refractory quartz may be extracted at the cost of a few shillings. The process is said to require only the decomposition of water, common salt, and lime by electrolysis, the gold being separated exactly in the manner adopted by nature to impregnate the water of the ocean, every ton of which is supposed to contain a certain number of grains of gold. We learn that a powerful syndicate has acquired the patent rights.

THE ELECTRIC LIGHTING ACT.

The President of the Board of Trade received a deputation on Thursday last representing the chief electric lighting companies, on the subject of the Act with which his name is so closely identified. The deputation was introduced by Lord Thurlow, the Chairman of the Brush Company, and included such well known representatives of the electric lighting industry as Sir Frederick Bramwell, Sir Daniel Cooper, Mr. R. E. B. Crompton, Mr. J. S. Forbes, Mr. R. Hammond, and Major Flood Page. It is now confessed in every quarter that the Electric Lighting Act is not to be numbered among the triumphs of legislation. The Chairman and Directors of the United Swan and Edison Company have therefore acted wisely in pressing an interview on their over zealous patron at the Board of Trade; and he in turn has acted with his usual discretion in according it. As was expected, he threw most of the blame on the interviewers; but one thing is beyond him, he cannot deny the utter failure of the Act for which he is responsible, nor the necessity for amending it if Electric Lighting is to enjoy the future that was predicted for it.

It was naturally argued that the undertakers of Electric Lighting were themselves responsible for some of the provisions of the Act, if not indeed for its initiation. This may be frankly admitted; for in the first place it was thought that compulsory powers of some kind would be required for carrying out the installations, and no doubt they are. The powers they got, however, were not at all what they bargained for, and what they had to give in exchange even for these was a great deal more than they would have voluntarily agreed to. But they had no choice. Having hooked his fish, Mr. Chamberlain would release it only on his own terms; and for these terms he alone is responsible. In the second place those provisions of the Act traceable to the companies, if we are not misinformed, stand good now, and are not challenged. Lastly, the Act as a whole, when it received its final touches, was protested against at the time, and was only allowed to pass because nothing better could be had. It was doomed to failure from the first, and if it had been framed solely in the interests of the existing gas companies, or the Corporation of Birmingham, it could hardly have been more hostile to the prospects of Electric Lighting interests.

We believe, however, that the Act was framed in no such spirit as that. What we do believe is that it had the misfortune, like many another parliamentary measure, to be cast in a political mould; and that the mould in this instance was a peculiarly narrow and tortuous one. Mr. Forbes was near the mark the other day when he told the shareholders of the Swan and Edison Company that the Board of Trade were so afraid of Electric Lighting becoming a frightful monopoly that they tied it up in every direction, and had succeeded in making it an impossibility. The letter which this Company has addressed to the President of the Board avoids all reflections of this kind. But no such reticence is imposed upon us. The only way to discredit the Act as it deserves is to expose the spirit in which it was framed; and we are confident that this spirit was prompted by a political fad, and nothing better. It was a spirit hostile to what are called vested interests. Vested interests! Why should not interests be vested? The term implies collective proprietorship; and the bare description of it in this simple form reveals how fanatical and captious must be the objectors who think to discredit it by applying to it an epithet which is perfectly harmless, but which has come to be one of the red rags of political strife. As a matter of fact, no interests can long exist unless they are vested, and no vestiture of them is possible except with the certainty of peaceful possession. This is a lesson which the assailant of existing interests may be slow to learn; but the lesson that new interests cannot arise in an atmosphere filled with the cry of confiscation has already been taught by the experiment with the electric lighting companies; and we take it that Mr. Chamberlain's willingness to receive a deputation from them is evidence that he is making progress in learning. His language on this point last Thursday confirms our impressions.

The letter which has been addressed to him is clear and unanswerable on the point just adverted to, and was ably handled by the deputation. Under the provisions of the Act the local authorities have compulsory powers of purchasing the business of the undertakers at a market valuation, whilst the undertakers have no powers to compel purchase on any terms whatever. Thus, if the business has succeeded, or by the time the working period has run out is about to succeed, the local authorities will buy; but if it has been unprofitable they will let it alone. Nothing but a political craze, we venture to say, could have blinded any otherwise sensible person to the impossibility of creating a new industry under such conditions as these, to say nothing of their iniquity. Nobody would start a chandler's shop on that

Digitized by Google

basis; and we know of no business so certain of success within a given number of years as to freely promise to sacrifice itself when the term has expired. Business men are perhaps as philanthropical as their customers, but not more so; and we have no more right to expect a number of men called shareholders to risk their money in the interest of the public than we have to ask the public to risk theirs in the interest of the shareholders. Heads I win, tails you lose, though smart enough to provoke a laugh, is not a motto for honest tradesfolk; and it certainly ought not to be the leading principle of an Act of Parliament framed by a British Minister of Trade. There are several other objectionable, impracticable, and even preposterous provisions which would alone render the Bill unworkable; but so long as the confiscatory clauses remain in it without very considerable modification, so long will no attempt be made to make any part of it workable.

CORRESPONDENCE.

THE WATT AND HORSE-POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been drawn to Mr. Preece's paper on "The Watt and Horse-power," which was read before the British Association at Montreal, and which is given in your issue of October 4th.

After a lapse of seven months from the time of the delivery of my addess to the Society of Telegraph Engineers and Electricians, Mr. Preece states at Montreal that I had spoken "of the watt as the unit of work, and had given its value in kilogrammetres;" and gives this as an instance of the "strange mistakes which are made in confusing the unit of power with the unit of work."

Now, on looking through my Address to find what I can have said to lead Mr. Preece to say that I had spoken of the watt as the unit of work, I looked in vain through the text; for I have not given a definition of the watt or spoken of it in any way except where it is used in its true sense, and where it *could not be understood*, by any intelligent person reading the context, as being used in any other than its true sense.

On page 24 I state "the number of watts $= c^2(a+f+r) =$ 5031·5 and the electrical horse-power $= \frac{c^2(a+f+r)}{746} = 6{\cdot}7461$, showing that watts and horse-power are things of the same name." But in a tabular statement on the same page, where there was not room to enter more than is absolutely necessary, I have put

Units of work, or watts, 5,012 ..... watts, 5,053.

Now, here there is no confusion as to watts, but any one very captious might say that I did not know what a *unit of work* was. It is quite impossible that these units of work could mean anything else than watts, and I hold that units of work per second are still units of work as much as revolutions per minute are still revolutions. In fact, Mr. Preece makes the same or even a greater mistake when, in his paper on "The Use of Secondary Batteries," he speaks of "the *total* electric energy being 815 watts."

But Mr. Preece's charge does not end here. In a supplementary note to my paper, consisting very much of tables of results, I have given the number of watts, and for the sake of convenience have indicated at the bottom of the table the multiplier employed to convert these into kilogrammetres per second; but as there was not room in the table, and as the term "kilogrammetres" could there have no other meaning than kilogrammetres per unit of time, it was unnecessary to state it more fully. On the succeeding page opposite to watts I have put (E C), to indicate clearly the meaning of watts.

In the large table at the end, where there was room, I have placed the heading, "Energy Absorbed per second in Watts," but I am afraid Mr. Preece will charge me with not knowing what is meant by a revolution, because in that table, in speaking of the revolutions of dynamos, I have not thought it necessary to put the heading, "Revolutions of Shaft *per Minute*." But what is the explanation which Mr. Preece gives of the matter. He states, as given in *The Electrician*, that "work done at the rate of a kilogrammetre per second = 981 watts $= g$ watts." Besides the omission of a point which alters the statement materially, I think that here we have some confusion, for surely g means a concrete quantity, *the acceleration due to the force of gravity*, whether measured in feet or in centimetres, per second, and therefore we must understand by Mr. Preece's statement "work done at the rate of a kilogrammetre per second" = 981 centimetres per second watts. Again, in the paragraph following the table we have the statement, "a standard sperm candle develops 4,000 foot-pounds per minute. Now, since a watt is equivalent to 44·2 foot-pounds per minute, it follows that a standard candle develops 90 watts per minute." So that, in other words, according to Mr. Preece, a standard candle develops 90 units of work per second per minute. The same mistake is repeated no less than four times in the same paragraph. I am afraid that if my address was confused we have here confusion worse confounded.—Yours, &c., W. GRYLLS ADAMS.

AN INDEX.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have recently received an expensive work on "Electric Lighting," from which I expected great things, but have been entirely disappointed.

Not one of the numerous works on that and kindred subjects which I have yet seen is to be compared with the contents of your excellent journal for details of description and range of practical information. When I look at the twelve noble volumes of *The Electrician*, it seems absurd to expect that any one book, published up to the same date, can add much, if anything, to what they contain, whilst the comparison is greatly in favour of your periodical.

There is but one drawback, which is the trouble and time required in searching out the buried treasures. There is a crying need for a really good index to the first twelve or thirteen volumes. An index in which everything referring to any *subject* is entered under *that as a heading*, whilst sub-headings may indicate whether the article comes under "Notes," "Correspondence," "Leading Articles," "Companies' Meetings," &c. We should have to look at one spot only to find all the references to any subject; whereas in the present half-yearly index it is necessary to look up any one subject under each of these several headings.

I would sooner by far pay ten or fifteen shillings for such an index as described than for all the books on "Electric Lighting," &c., which I have ever yet seen. Its publication would be a boon to large numbers besides myself. May we hope for it?—Yours, &c., J. C. CUFF.

The Eastern Extension, Australasian, and China Telegraph Company, Singapore, October 15, 1884.

HENRY FAWCETT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your journal is so intimately associated with the latest and most interesting development of the public department of the Post Office that I dare say you will kindly find space for a few words of mine which the death of the Postmaster-General seems to suggest. I have had to do with several of the figure heads of the Post Office, and undoubtedly Mr. Fawcett was the best type. He, however, was too deferential to his predecessor to be sufficiently impartial in carrying out every effort he evidently desired in order to advance the telegraph service of the State. I have myself waited many years for the Post Office to keep faith with me in so simple a matter as naming a time for the meeting of the referees which have been appointed on both sides. Mr. Fawcett had this urged upon his attention by me four times in the months of July and August, 1880, before any answer was given, and then he stated merely that "he

Digitized by Google

did not feel called upon to enter into the past history of the case." I wrote to him again, pointing out the injustice of leaving a matter of such serious importance to me unfinished, and only because a new Ministry had appointed a new chief, but although I again asked twice for his attention to the matter, he made no reply.

In its eulogy of Henry Fawcett the current number of the *Spectator* has the following outburst—

"O light unto thy country, who hast lent
Eyes to the dim hope of the ignorant!
Why the great form of Justice standeth blind
Thou dost make plain."

My experience, however, has not carried me as far as this. In fact, after seven years I would still repeat and shall urge upon successive Postmasters-General what I suggested in my pamphlet on "Sound Constitutional Principles in Theory and Practice," then published by Longmans, that "it would be highly instructive if a return was made to Parliament of the number of petitions presented to the Crown, say during the present reign, and of the number of those in which redress was obtained, or even in which the complaints of the petitioners received any serious attention. The scope of this field of usefulness is great, and fully worth the attention of a vigorous and independent successor even to Henry Fawcett.—Yours, &c.,

RICHARD HERRING.

27, St. Mary's-road, Canonbury.

ALTERNATE CURRENT MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in the current number of *The Electrician* a report of Dr. Hopkinson's paper recently read before the Society of Telegraph Engineers on the electro-mechanical property of the alternating current to synchronise the rotations of the armatures of a number of magneto-electric machines when their circuits are connected. May I be permitted to state that this remarkable property of the current was discovered by me in 1868, and is fully described in the *Phil. Mag.* for January, 1869.

As my paper was much in advance of the electrical knowledge of the time, and may not have had many readers, I shall be glad if you will find a place for the following copy of it in your valuable journal.—Yours, &c.,

H. WILDE.

Rockside, Alderley Edge, Cheshire,
Nov. 17, 1884.

ON A PROPERTY OF THE MAGNETO-ELECTRIC CURRENT

To Control and Render Synchronous the Rotations of the Armatures of a Number of Electro-Magnetic Induction Machines.*

The discovery of the property which I am about to describe arose out of the efforts which have been made, during the last two years, to reduce the internal heat generated in an electro-magnetic machine by the induction currents set up in the electro-magnet and armature by the rapid magnetisation and demagnetisation of the latter. This heating of the armature (as is well known) was first observed by Dr. Joule in 1843, as the result of a delicate investigation on the quantitative relation existing between ordinary mechanical power and heat.† In the electro-magnetic machines of my invention this phenomenon unfortunately manifests itself on an alarming scale, so much so that the armature of the 10in. machine rises in the course of a few hours to 300° F. and upwards; and were the action of the machine to be continued for any lengthened period, the insulation of the armature coils would be in great danger of being destroyed.

One method of mitigating this evil was to construct the machine of smaller dimensions, so as to afford greater facilities for the dissipation of the heat by radiation and conduction. But even in the smaller machines an inconvenient residuum of heat still remained when the machines were worked continuously for a considerable time, such as to render it desirable to adopt some means for abstracting the heat more rapidly. By means of a current of water circulating in the hollow brass segments which form part of the magnet-cylinder, Mr. Charles E. Ryder, the skilful manager at the works of Messrs. Elkington and Co., has happily succeeded in so far reducing this heating so as to permit of the machines being worked for days and nights together without intermission, and without any sensible diminution of the power of the current.

The machines which have been found to be the most efficient and economical in their working are those which have armatures from 3½in. to 4in. in diameter. The armatures are driven at about 2,000 revolutions per minute, and the water, after having passed through the magnet-cylinder, is used for supplying the boilers which furnish the power for driving the machines.

I have already shown elsewhere that the current from a small magneto-electric or electro-magnetic machine is sufficient to excite the great electro-magnet of the 10in. machine; and it has been further found, by my friend Mr. G. C. Lowe, that the current from one small machine is sufficient to excite simultaneously the electro-magnets of several small machines. In a number of 3½in. machines which have been constructed under my direction for Messrs. Elkington and Co. for the electro-deposition of copper on a large scale, the currents from two 3½in. electro-magnetic machines are made to excite the electro-magnets of twenty similar-sized machines to a degree sufficient to bring out the maximum dynamic effect of each machine. The electro-magnets of the two 3½in. exciting machines are charged by the current from a small 2½in. magneto-electric machine; but I have found that nearly as good a result may be obtained from the twenty machines by dispensing with the small magneto-electric machine, and employing the residual magnetism of the two 3½in. exciting machines in a manner similar to that described, almost simultaneously, by Mr. Farmer,* Messrs. Varley,† Mr. Siemens,‡ and Sir Charles Wheatstone.§

So far I have adverted principally to the means by which a very serious defect in the practical working of the new induction machine was remedied, a defect which many of my friends, who were unacquainted with the efforts which have been made to overcome it, have considered to be fatal to the success of what seemed likely to be a useful invention. But while the difficulty arising from the heating was now obviated, the subdivision of the materials of one large machine into a number of small ones gave rise to another defect which it was also found necessary to overcome; for although the armatures of several machines might be driven nominally at the same speed from the same driving-shaft, by means of straps, yet when the combined direct current from several commutators was required, the want of perfect synchronism in the revolution of the armatures operated to produce a diversion of the currents of some of them through the coils of others, which were at the neutral point of their revolution; and consequently the maximum useful effect of the combined currents could not be obtained.

As the high speed at which the machines were driven precluded the employment of toothed gearing, the only method which seemed at all feasible for producing the requisite synchronism of the armatures was to place a number of the machines in a straight line, and connect them together by means of a clutch fixed on the end of each armature-spindle. The chief objection to the carrying out of this arrangement was the difficulty of providing the requisite means for preserving the synchronism of the system, when any of the intermediate machines were disabled by accident, or stopped for repairs, so that practically it would not have been found convenient to work more than two machines geared together in the manner described.

It was while experimenting with a pair of machines so geared together that I first observed the phenomenon which forms the subject of this communication. These machines were arranged for producing the electric light, with a view to their application to lighthouse illumination. The armatures were 4in. in diameter, and each of them was coiled with a copper wire conductor 280ft. long and ⅛ of an inch in diameter. The currents were taken from the armatures by means of copper brushes rubbing against metal rings connected respectively with the ends of the armature coils, and were therefore in alternate directions. It has been found that alternating currents are much better adapted for the production of a constant electric light at a fixed point in space than the current which has been rectified by means of a commutator.

The clutch, by which the armatures were connected, consisted of two iron discs about 4in. in diameter, having, in the face of one, two iron pins which could be guided into two corresponding holes in the face of the other. These discs could be engaged or disengaged either when the machines were at rest or in motion. The relative positions of the pins and holes in the discs were such that the armatures might be engaged in reversed positions of half a revolution when required.

Each of these 4in. machines, when making about 2,000 revolutions per minute, was of itself capable of producing a very efficient electric light; and when the two armatures were clutched together in such a position that the united positive currents from both machines proceeded from one polar terminal simultaneously with the united negative currents from the other polar terminal, the sum of the currents of the two machines was obtained. On the other hand, when the armatures were clutched together in the reverse position without any change being made in the armature connections, no current was produced outside the two machines.

These experiments, besides exhibiting the necessity of synchronous rotation, further showed that the armatures must also occupy the same relative position in the magnet-cylinders in order that the combined current from the two machines might be obtained. It now occurred to me to see to what extent the want of synchronism in the armatures would affect the magnitude of the current. The armatures were therefore unclutched and allowed to revolve independently of each other, in the same manner as when the attempt was made to take the combined *direct* current from the

Digitized by Google

commutators. After the *alternating* current had been transmitted through the electric lamp for some time, I was surprised to find that there was no perceptible diminution in the amount of light produced from the carbon points, and that the current would melt very nearly the same quantity of iron wire as when the armatures were clutched together. On examining into the circumstances attending this unexpected phenomenon, I first observed that, whenever the machines were stopped, the pins and holes in the respective discs were exactly opposite each other, and that, while the armatures were revolving, the two discs could at all times be engaged and disengaged with the greatest facility. Moreover, even when before starting the machine the discs were set a quarter or half a revolution out of the position in which the maximum amount of current was obtained, it was found that, after the armatures had been revolving for a few moments, the discs resumed their normal position with respect to each other (as indicated by the action of the clutch)—thereby exhibiting not only the synchronous rotation of the armatures, but also that the machines contained a principle of self-adjustment to the position in which the maximum effect of the combined current was obtained. It will therefore be evident that this property of the current, to maintain the synchronism of the armatures, renders it unnecessary to employ mechanical gearing of any kind for that purpose.

Proceeding further in this investigation, I found that, in order to produce synchronous rotation, it was not at all essential that the circuit which conveyed the combined currents for producing the light should be completed, provided that the ends of the coils of each armature were connected respectively with the same metal plates which formed the polar terminals of the machines. In this case the armatures adjusted themselves to their normal positions even more readily than when the current was producing the light. The accompanying diagram will assist in explaining these observations more fully.

Let D and D represent the two armature-coils, which, though each 280ft. long, may virtually be represented by a single turn; E E the two outer extremities of the coils, both connected by means of the metal rings and brushes with the metal terminal plate F; G G the inner extremities of the same coils, similarly connected with the terminal plate H. The synchronous rotation of the armatures and coils D and D, as I have said, occurs either when the light is produced by the combined currents transmitted from the polar terminals F and H, or when the circuit which conveyed these combined currents is broken.

The synchronism, however, is no longer preserved when a short circuit is made between the terminals F and H by substituting a good conductor for the carbon points, or for the long piece of iron wire which was melted. Nor, again, was this synchronism preserved when contact between the metal plate H and one of the ends, G, of the coil was broken. In the latter case it was observed that, whenever contact between G and H was made and broken, a bright spark appeared at the point of disjunction so long as the rotation was not synchronous; but when the synchronism was reestablished, only a trifling residual spark was visible.

Although the synchronous rotation was preserved when the terminals F H, from which the combined current was transmitted, were disconnected from the electric lamp, yet it will be seen, from an inspection of the diagram, that a complete metallic circuit was in fact always formed between these terminals through the coils themselves. Now, when the coils D D happen to be at the same moment in that position during their revolution in which they are producing the maximum and minimum amount of current respectively, as must often be the case where there is no synchronism, that current which is at the maximum rushes through the coil which is producing the minimum current, as is shown by the spark at the point where contact is broken between G and H. The effect of this passage of the current from one coil to the other is to accelerate or retard the rotation of the armature (according to the direction of the current) until synchronism is established.

That this influence of one coil upon the other operates in the manner described was easily shown by the following experiment:—The driving-strap of one of the armatures was removed, so that only one of the armatures should be producing a current, while the magnetism of the electro-magnets of both machines was, as usual, maintained to the same degree. On placing the stationary armature with its coil in a suitable position in relation to the magnet-cylinder for producing electro-magnetic rotation, and setting the other armature in motion, the stationary armature with its coil oscillated rapidly in arcs of very small amplitude, the oscillations corresponding in number with the alternations of the current. As the amplitude of the oscillations in this experiment was limited by the *vis inertiæ* of the armature, and in order that the effect of one pulsation only on the armature might be observed, contact was made and broken suddenly between the plate H and the end G of the coil by a sort of tapping motion, when the stationary armature was suddenly jerked round nearly a quarter of a revolution, sometimes in the direction in which it would have been driven by the strap, and at other times in the opposite direction, according as the alternating electrical wave which happened to be passing at the instant of making contact was positive or negative.

We have now seen, in the results obtained with the rotating and stationary armatures, a cause sufficient to account for their synchronism when revolving together—the absence of synchronism observed when the terminals F and H were bridged over by a conductor having comparatively little or no resistance being occasioned by the controlling current traversing the short circuit established between the terminals F and H, instead of the 280 feet of resistance presented by either of the coils when approaching the neutral point of their revolution. The absence of synchronism observed when the direct current was taken from the machines by means of commutators, is caused by the direction of the current being coincident with that which they would receive by induction from the electro-magnets, and consequently opposite to that which tends to impart an accelerating or retarding impulse to the armatures.

Having obtained the full effect of the combined alternating currents from the two machines without any mechanical gearing, it yet remained to obtain the combined direct currents from the machines in the same manner. A pair of rings and a commutator were therefore fitted upon one of the armature-spindles, which was made sufficiently long for the purpose, and metallic connection was established between the rings of each machine and the commutator on the prolongation of the armature-axis. As the commutator necessarily revolved synchronously with the two armatures, it was found that the combined alternating currents were rectified just as if they had proceeded from only one machine, and were consequently available for electro-deposition, or for any other purpose for which a direct current might be required.

Although this property of synchronous rotation has as yet been observed only in the case of several pairs and a triple combination of machines, yet there is no reason for supposing that it may not be extended to any number of machines that may be conveniently worked together from the same prime mover. It is necessary, however, to observe that as the controlling power of the current is only calculated to correct such minute deviations from synchronism as it is beyond the power of mechanical skill to prevent, the driving and driven pulleys should be respectively as nearly as possible of the same diameters, as the correction of any considerable difference in the number of the revolutions of the armatures, caused by differences in the diameter of the pulleys, must necessarily be attended by a corresponding diminution of the useful effect of the current outside the machines.

Before concluding this communication I wish to direct attention to an important property of the magneto-electric circuit which renders the commonly accepted theory, by which the generation and propagation of the electric influence in voltaic circuits is explained, inapplicable to those circuits which are entirely metallic. Reference to this property is all the more called for at the present time, as I find that a want of acquaintance with it has given rise to no small amount of misconception on the part of several eminent mathematicians and electricians who have examined my experiments on the electric condition of the earth, and the method by which I have thought proper to estimate the magnitude of powerful induction currents*.

The intensity of a voltaic current, as represented by the mathematical theory of Ohm, is equal to the electromotive force divided by the internal resistance of the battery; and from this theory it is inferred that an electro-motor, in order to overcome a great external resistance, must itself possess a correspondingly great internal resistance. A further consequence deduced from this theory is that the maximum useful effect of a given electro-motor is obtained when the external and internal resistances are equal.

Now, this mode of estimating the magnitude of an electric current does not apply to the circuits on the armatures of my machines. Taking for example the results obtained from the quantity armature of a 10in. machine:—The dimensions of the coil of this armature may be represented by a bar of pure copper, 67ft. long, and having a sectional area of 1·6 square inch; so that the resistance which this circuit presents to the passage of a current, when compared with that of the liquids in a voltaic battery, is practically null. When the coil is in full action it will melt 15in. of thin iron wire ·035 of an inch in diameter, or the same length of ¼in. iron rod with equal certainty, and will electrolyse acidulated water in at least 16 voltameters in series; so that the resistance outside the circuit, whether estimated by the 15in. of thin wire melted or by the number of electrolysing-cells in series, is more than a hundred times as great as that of the coil in which the current is generated.

Moreover I have found that whenever a voltaic battery and a magneto-electric machine will melt an equal length of wire, the power which these electro-motors have to overcome external resistance, as measured by the number of voltameters in series, is also equal. And, generally, the power of an electro-motor (whether voltaic or magneto-electric) to overcome external resistance is directly proportionate to the length of wire which it will melt.

From a consideration of these results, it will be seen that one of the fundamental elements which enters into the theory of Ohm is found wanting when that theory is applied to the estimation of the magnitude of currents generated in circuits entirely metallic.

MM. Jamin and Roger, in a recent number of the *Comptes Rendus* of the Academy of Sciences†, have also pointed out the discrepancy here referred to in the application of Ohm's theory to magneto-electric circuits. I am, however, by no means prepared to admit the correctness of the views advanced by these physicists in their endeavours to reconcile the facts observed with established theory; besides which, other anomalies present themselves when the customary formulæ are applied to magneto-electric circuits, a consideration of which must ultimately lead to the enunciation of laws much more general in their application than those with which we are at present familiar.

P.S.—Since this paper was read it has occurred to me that a comparison might be attempted to be drawn between the controlling power of the magneto-electric current over the rotations of a number of armatures, and that of the voltaic current over the oscillations of a number of pendulums. Beyond the fact that synchronism is produced in both cases through the agency of an electric current, there is no further resemblance

* *Philosophical Magazine*, August, 1868. † *Ibid*, October, 1868.

Digitized by Google

between the two actions. In the case of the armatures the synchronism is produced by the mutual action of several rotating bodies upon one another, or by the dominant influence of several bodies upon one; whereas in the case of the pendulums the synchronism of the system is produced by the influence of one body alone upon several. Again, the synchronism of a number of pendulums is only accomplished by the skilful adaptation of means to an end, while the synchronous rotation of a number of armatures is a phenomenon which exhibits itself without the exercise of any ingenuity whatever; and, so far as I have studied this peculiar electro-mechanical action, no amount of ingenuity can produce the synchronous rotation of the armatures by means of the voltaic current, as magneto-electric currents and circuits seem absolutely essential to the attainment of this result.

ON THE INFLUENCE OF CENTRIFUGAL FORCE ON HIGH SPEED BELTING.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 15.)

It is interesting to note that size of pulley and speed are inversely proportional; thus, if at 1,000 revolutions a 16in. pulley is the best size to transmit a certain power with a given belt, at 2,000 revolutions the same belt would transmit the same power best, if used with an 8in. pulley. In fact, the most advantageous belt speed is a constant for each case. It should also be noted that $R\,n$ (the belt speed) remains unaffected by proportionate changes in the power transmitted and the size of belt. That is to say, if we wish to transmit twice the power we would employ a belt twice as wide or twice as thick, but we would not alter the belt speed—this remains the most advantageous one as long as the cross sectional area of the belt is varied in proportion to the power transmitted. By inserting the above value for R into the formulæ for T_0 and β we find

$$T_0 = (2\epsilon\gamma)^{\frac{1}{3}} (\kappa\eta\,H.P.)^{\frac{2}{3}}$$

and β exactly half that value. The calculation need not be gone through here, but we note the result. The smallest possible strain in the driving side of a belt is therefore

$$T\,min. = 1{\cdot}5\,(2\epsilon\gamma)^{\frac{1}{3}} (\kappa\eta\,H.P.)^{\frac{2}{3}};$$

or, if we insert the numerical values for ϵ and η, and neglect fractions,

$$T\,min. = 39\,\sqrt[3]{\gamma\,\kappa^2\,H.P.^2}.$$

This formula is applicable in all cases where the size of the belt, and consequently its weight γ per foot run are determined beforehand, but it cannot be used for finding the size of the belt at one operation.

The size of the belt to be used for any given case depends on the amount of tension we allow per square inch of cross section. Let this be σ pounds, and let the area of cross section in square inches be a, then

$$T\,min. = \sigma\,a.$$

Since γ depends on the cross-sectional area, and since that is not known beforehand, it will be convenient to substitute another expression for it, viz.,

$$\gamma = \frac{a\,\delta}{144},$$

where δ is the weight of one cubic foot of belt in pounds. By introducing these values into the above equation for the minimum strain and again neglecting fractions we obtain an expression for the least possible area of cross section of belt in square inches.

$$a = 21\,\kappa\,H.P.\sqrt{\frac{\delta}{\sigma^3}}$$

It must be borne in mind that this minimum of area can only be used on condition that the belt is caused to run at the most advantageous speed as given by the formula for $R\,n$; at any other speed the area would have to be greater. By inserting the values for $\epsilon\,\eta$ and γ into the formula for $R\,n$, and again neglecting fractions we find

$$R\,n = 375\sqrt{\frac{\sigma}{\delta}};$$

and since $2\,\pi\,R\,n$ is the speed of the belt in feet per minute, we have

$$\text{belt speed} = 2{,}350\sqrt{\frac{\sigma}{\delta}}.$$

From this it will be seen that the most advantageous belt speed is independent of the horse-power transmitted, of the coefficient of friction, of the arc spanned, and of the size of the belt. It depends only on the proportion between the specific gravity of the belt and the working strain per square inch. This is a very remarkable result, but quite consistent with experience. Practical men have settled long since that ordinary single-leather belting, if driving high speed machinery, should run at speeds varying between 3,000ft. and 6,000ft., the choice of any definite speed between these limits being more a matter of convenience than anything else. To test our formula by the light of practical experience we will calculate the best speed for an ordinary case. The weight of one cubic foot of belting can be taken as 69lbs., the working strain should not exceed 300lbs., say we fix σ at 280lbs. per square inch. The best speed is then $2{,}350\sqrt{\frac{280}{69}} = 4{,}730$ft. per minute, therefore within the limits fixed by practice. If instead of single belting we had to do with double belting, we should have to put $\sigma = 200$ pounds, and the best belt speed would be about 4,000 feet a minute. Here we see how theory confirms the old experience known to every millwright, that double belts should not run at so high a speed as single belts.

To make the present investigation of some use for the design of belts and pulleys, it will be necessary to repeat here a few of the simple formulæ above obtained. Generally speaking one of the two following problems presents itself. Either all the data are given and the working strain per square inch of belt is to be determined, or only the horse-power to be transmitted and the number of revolutions are given and the other data are to be found.

In the first case we find the tension in the tight side of the belt in pounds

$$T = \frac{\kappa\,5{,}250\,H.P.}{n\,R} + {\cdot}000344\,\gamma\,R^2\,n^2,$$

and the corresponding working strain per square inch

$$\sigma = \frac{T}{a}.$$

In the second case we would first determine the most advantageous belt speed in feet per minute by using the formula

$$2\,\pi\,R\,n = 2{,}350\sqrt{\frac{\sigma}{\delta}},$$

and from this we obtain the diameter of the pulley, since the number of revolutions is known.

As regards the area of belt section it is customary in low-speed belting to add about 10 per cent. to the tension in the tight side, as given by the formula, and to determine the area with reference to this increased figure. This is done to provide against an error due to uncertainty in the coefficient of friction, and since this uncertainty exists equally in the case of high-speed belting it will be best to allow 10 per cent. also in this case. In addition to this we must allow something for a variation in speed. It may not always be possible to run a belt exactly at the best speed. Existing pulleys might have to be used, or the governor of the engine may not allow the speed to be attained with mathematical precision. To provide for these cases 5 per cent. extra area would probably be sufficient. Adding then 15 per cent. in all as a safe margin we find the cross-sectional area of the belt. It is

$$a = 24\,\kappa\,H.P.\sqrt{\frac{\delta}{\sigma^3}}$$

Digitized by Google

Example.—A dynamo requiring 30 horse-power in the belt is to be driven at 900 revolutions per minute. We allow a working strain of $\sigma = 250$lb., and the weight of one cubic foot of belting is 69lb.

$$2\pi 900 R = 2{,}350\sqrt{\frac{250}{69}} = 4{,}450\text{ft.}$$

From this we find the diameter of pulley to be 19″. If the belt spans 0·45 of the circumference, and the coefficient of friction be taken at 0·29, a figure which is correct for moderately greasy belts on iron pulleys, we find $\kappa = 1{\cdot}83$, and $a = 2{\cdot}75$ square inches. To obtain this area with a single belt it would have to be between eight and nine inches wide and between $\frac{3}{8}$in. and $\frac{5}{16}$in. thick. The strain in the driving side would be about 600lb.; of this force 400lb. would be required to transmit the power by means of a weightless belt, whilst the remaining 200lb. counteract the effect of centrifugal force.

THE THEORY OF ALTERNATING CURRENTS.*

BY J. HOPKINSON, F.R.S.

(CONTINUED FROM PAGE 13.)

III. *Suppose the terminals of an alternate-current machine are connected to a pair of conductors, the difference of potential between which is completely controlled by connection with other alternate-current machines.*

Let γ and R be the coefficient of self-induction and the resistance of the machine and its own conductors up to the point at which the potential is completely controlled. Let the difference of potential of the main conductors be $A \sin. \frac{2\pi t}{T}$, and let the electromotive force of the machine be $B \sin. \frac{2\pi(t-\tau)}{T}$.

Equation of motion is

$$\gamma x' + R x = B \sin. \frac{2\pi(t-\tau)}{T} - A \sin. \frac{2\pi t}{T},$$

whence

$$x = \frac{1}{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2}\left[B\left\{R \sin. \frac{2\pi(t-\tau)}{T} - \frac{2\pi\gamma}{T} \cos. \frac{2\pi(t-\tau)}{T}\right\} - A\left\{R \sin. \frac{2\pi t}{T} - \frac{2\pi\gamma}{T} \cos. \frac{2\pi t}{T}\right\}\right]$$

electrical work done by the machine in unit of time

$$= x B \sin. \frac{2\pi(t-\tau)}{T}$$

$$= \frac{1}{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2}\left[\frac{B^2 R}{2} - \frac{AB}{2}\left\{R \cos. \frac{2\pi\tau}{T} + \frac{2\pi\gamma}{T} \sin. \frac{2\pi\tau}{T}\right\}\right]$$

if τ be positive, that is, if machine be lagging in its phase, work done is less than if it be negative; hence τ will tend to zero, or the machine will tend to adjust itself to add its currents to that of the system of conductors. The machine may act as a motor *even though its electromotive force be greater than that of the system*, for let

$$\frac{R}{\frac{2\pi\gamma}{T}} = \tan. \frac{2\pi\phi}{T},$$

work (electric) done by machine

$$= \frac{B^2 R}{2\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}} - \frac{AB}{2\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}^{\frac{1}{2}}} \sin. \frac{2\pi(\phi+\tau)}{T}$$

This has a minimum value when $\phi + \tau = \frac{T}{4}$, and then the mechanical work done by machine or electrical work received by the machine

$$= \frac{B}{2\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}^{\frac{1}{2}}}\left\{A - \frac{RB}{\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}^{\frac{1}{2}}}\right\}$$

and this is positive provided

$$\frac{A}{B} > \frac{R}{\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}^{\frac{1}{2}}}$$

There are two or three other problems of sufficient interest to make it worth while giving them here, although not directly relating to alternate current machines coupled together.

IV. *To determine the law of an alternate current through an electric arc.*

It has been shown by Joubert that in an arc the difference of potential is of approximately constant numerical value, reversing its value discontinuously with the reversal of the current, probably at the instant of reversal of current. We shall assume, then, that there is in the arc a constant electromotive force, A, always opposed to the current, except when the current ceases, and that then its value is zero.

The equation of motion is

$$\gamma x' + R x = E \sin. \frac{2\pi t}{T} \mp A$$

the negative sign being taken when x is $+\infty$, the positive when x is negative. Solving generally

$$x = \mp\frac{A}{R} + \frac{E}{\left(\frac{2\pi\gamma}{T}\right)^2 + R^2}\left(-\frac{2\pi\gamma}{T} \cos. \frac{2\pi t}{T} + R \sin. \frac{2\pi t}{T}\right) + C e^{-\frac{R}{\gamma}t},$$

this equation will continuously hold good for a half period from $x = 0$ to $x = 0$ again, but at each half period the arbitrary constant C is changed with the sudden change of sign of A. It is determined by the consideration that if, for a certain value t_0 of t, x should vanish, it shall vanish again when $t = t_0 + \frac{T}{2}$. This applies to the case when E is sufficiently large, as is practically the case, but if the current should cease for a finite time this condition will be varied, and instead of it we have the condition $x = 0$ when $E \sin. \frac{2\pi t}{T} = A$. This latter case I do not propose to consider further.

Let $$\frac{2\pi\gamma}{RT} = \tan. \frac{2\pi t_1}{T}$$

$$x = \mp\frac{A}{R} + \frac{E}{\sqrt{\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}}} \sin. \frac{2\pi(t-t_1)}{T} + C e^{-\frac{R}{\gamma}t}$$

putting $t = t_0$ and $t = t_0 + \frac{T}{2}$ we have

$$0 = -\frac{A}{R} + \frac{E}{\sqrt{\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}}} \sin. \frac{2\pi(t_0 - t_1)}{T} + C e^{-\frac{R}{\gamma}t_0}$$

$$0 = -\frac{A}{R} - \frac{E}{\sqrt{\left\{R^2 + \left(\frac{2\pi\gamma}{T}\right)^2\right\}}} \sin. \frac{2\pi\gamma(t_0 - t_1)}{T} + C e^{-\frac{R}{\gamma}t_0} \cdot e^{-\frac{RT}{2\gamma}},$$

equations to determine t_0 and C.

* Paper read before the Society of Telegraph Engineers and Electricians on November 13th.

Digitized by Google

Eliminating C,

$$\frac{RE}{A\sqrt{\left\{R^2+\left(\frac{2\pi\gamma}{T}\right)^2\right\}}}\cdot\sin.\frac{2\pi(t_0-t_1)}{T}=-\tanh.\frac{RT}{4\gamma}.$$

Having obtained t_0, C is given by equation

$$\frac{2A}{R}=Ce^{-\frac{R}{\gamma}t_0}\left(1+e^{-\frac{R}{2\gamma}T}\right).$$

This gives the complete solution of the problem.

A case of special importance is that in which R is small; let us therefore consider the case R = 0, the solution then is

$$\gamma x=-\frac{T}{2\pi}E\cos.\frac{2\pi t}{T}-At+C.$$

In the same was as before

$$E\cos.\frac{2\pi t_0}{T}=\frac{A\pi}{2},$$

$$C=A\left(t_0+\frac{T}{4}\right).$$

The limiting case to which the solut ion applies is given by $x'=0$ when $t=t_0+\frac{T}{2}$.

$$E\sin.\frac{2\pi t_0}{T}=A,$$

whence $$E^2=A^2\left(1+\frac{\pi^2}{4}\right),$$

or $$A=E\times 0{\cdot}538.$$

Roughly, we may say that, in order that the current may not cease for a finite time, E *must be at least double of* A; A will of course depend upon the length of the arc. The work done in the arc will be proportional to the arithmetical mean value of the current taken with regard to sign. This is of course quite a different thing from the mean current as measured by an electro dynamometer. Let us examine what error is caused by estimating the work done in the arc as equal to the current measured by the dynamometer multiplied by the mean difference of potential.

The actual work done per second

$$=\frac{2A}{T}\int_{t_0}^{t_0+\frac{T}{2}}x\,dt$$

$$=\frac{2A}{\pi\gamma}\cdot\frac{T}{2\pi}\cdot\sqrt{E^2-\frac{\pi^2A^2}{4}}.$$

The mean square of the current, as measured by the electro-dynamometer is

$$\frac{2}{T}\int_{t_0}^{t_0+\frac{T}{2}}x^2dt=\frac{T}{2\pi\gamma}^2\left\{\frac{E^2}{2}-2A^2\right\}+\frac{A^2T^2}{48\gamma^2}$$

and the work done by this current is apparently the square root of the above expression multiplied by A. It is easy to see that this is greater in all cases than the work done, but it is worth while to examine the extent of the error. If we treated the arc as an ordinary resistance, we should assume work per second

$$=\frac{A}{\gamma}\sqrt{\left(\frac{T}{2\pi}\right)^2\left(\frac{E^2}{2}-2A^2\right)+\frac{A^2T^2}{48}}$$

Taking a fairly practical case, assume $A=\frac{2}{5}E$, we have actual work per second

$$=\frac{A^2T}{\gamma}\cdot\frac{1}{\pi^2}\sqrt{\frac{25}{4}-\frac{\pi^2}{4}}$$

$$=\frac{A^2}{\gamma}T\frac{\sqrt{15}}{20}\text{ nearly,}$$

work done estimated by electro-dynamometer

$$=\frac{A^2T}{\gamma}\sqrt{\frac{1}{40}\left(\frac{1}{2}\frac{25}{4}-2\right)+\frac{1}{48}}\text{ nearly}$$

$$=\frac{A^2T}{\gamma}\frac{1}{20}\sqrt{\frac{235}{12}}$$

or nearly $\frac{1}{6}$ part too much. This will suffice to show that the matter is not a mere theoretical refinement. Another erroneous method of estimating the power developed in an arc is, to replace by a resistance and adjust this resistance till the current, as measured by an electro-dynamometer, is the same as with the arc, and assume that the work done in the resistance is the same as the work done in the arc.

Returning to the expression

$$\frac{2A}{\pi\gamma}\cdot\frac{T}{2\pi}\sqrt{E^2-\frac{\pi^2A^2}{4}}$$

we may inquire, given T A and the dimensions of the machine, how ought it to be wound or its coils connected that most work may be done in the arc? If the number of convolutions be varied, E will vary as the convolutions, γ as their square, therefore $\gamma\propto E^2$; we are therefore to determine E so that $\frac{1}{E^2}\sqrt{E^2-\frac{\pi^2A^2}{4}}$ is a maximum which occurs when $E=\pi A$. When the resistance of the circuit is taken into account this result will be modified. It suffices to prove that it is desirable that the potential of the machine should be materially in excess of that required to maintain the arc.

(TO BE CONTINUED.)

TROUVE'S PORTABLE LAMPS.

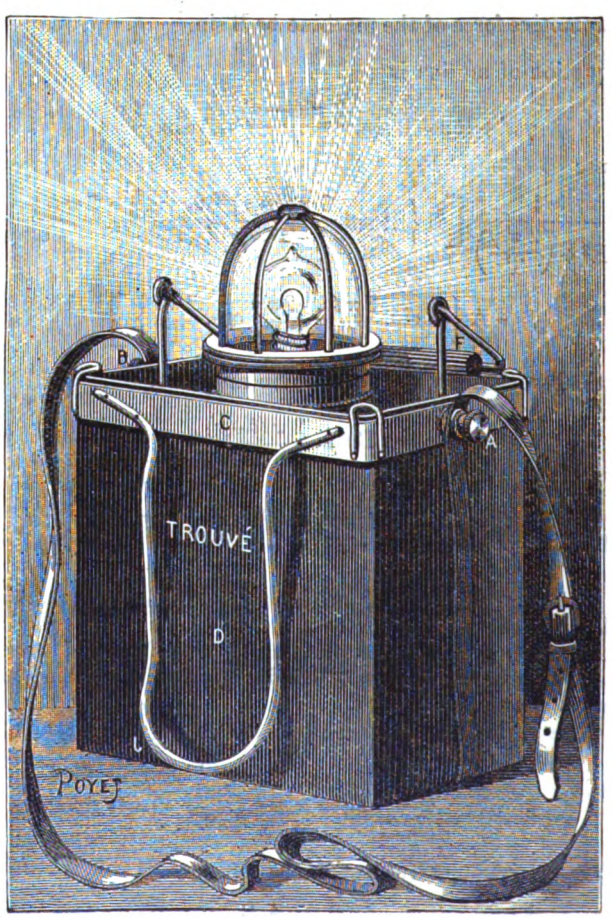

FIG. 1.

In consequence of several accidents which have lately occurred at Paris, due to escapes of gas, forming with the air an explosive mixture, lighted inadvertently or carelessly, a special committee was

Digitized by Google

appointed to study the question. This committee finally adopted the lamp invented by M. Gustave Trouvé, of Paris, which has lately been described to the Société Technique du Gaz, and was on the 3rd inst. brought by M. Jules Jamin before the Académie des Sciences.

The leading principle of this portable apparatus, which is illustrated below, is that the current is sent through the carbon filament of the incandescent lamp by the immersion of the carbon plates of the battery in the exciting solution, while the light ceases on the interruption by their withdrawal; and this immersion is brought about by the mere placing of the lantern in the position in which it is required for use, the withdrawal being effected automatically by its removal from that position. It follows that the energy of the battery is only expended while the lamp is actually incandescent, and that no danger is to be feared, in an explosive mixture, for use in which the lamp is primarily destined, by sparks produced by the action of any commutator for making and breaking contact. Moreover, in some varieties of the lamp, intended for domestic use, the intensity of the light may be regulated by the degree of immersion of the carbons.

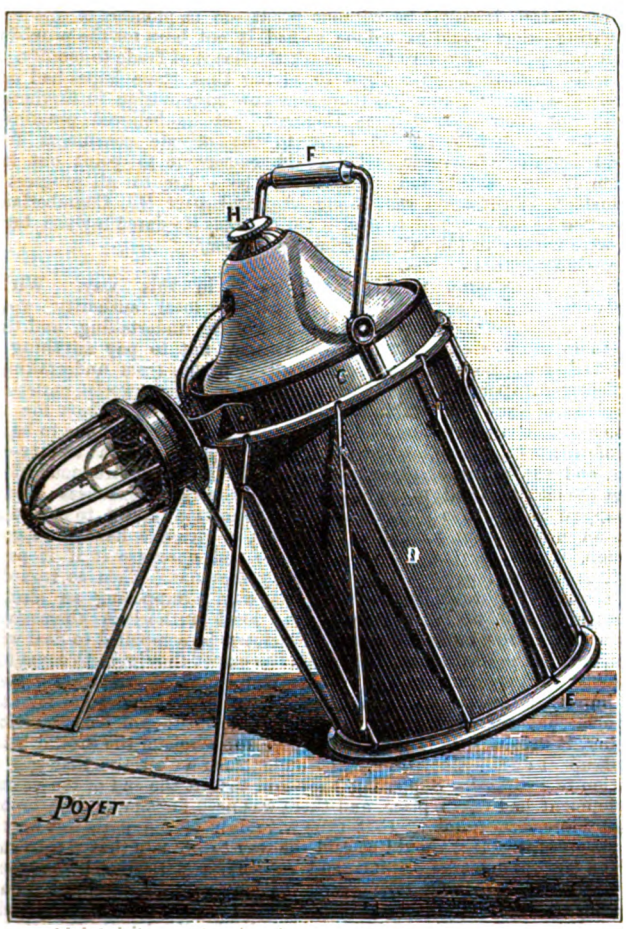

FIG. 2.

Fig. 1 shows a portable form of battery, and lamp combined, the latter becoming incandescent on the apparatus being set down, but not so when hung over the shoulder by the strap, carried by the handle F, or suspended by the hook J, attached to the ring C encircling the case D. In another form, the converse takes place; that is to say, the lamp becomes incandescent when carried, but not when set down; or again, when suspended, but not when carried or set down. When these lamps are supplied to firemen or gasmen, they are so arranged that, on an alarm being raised, each man takes up his lamp and carries it, thus keeping the carbons out of the solution. Arrived at the spot where he may have to enter a room with an explosive mixture, he hangs the apparatus over his shoulder, and thus allows the carbons to descend into the solution, turning on the light but leaving both hands free.

Figs. 2 and 3 show the incandescent lamp fixed to the side of the ring C surrounding the upper portion of the battery case D. When the apparatus is set down, it rests upon the plate G, which, attached to the cover, by a rod passing through the middle, lifts the carbons out of the solution. But when the apparatus is carried by the handle F, the weight of the plate G and of the cover and carbons keeps the latter immersed; and the lamp shines forth. The milled head H of a quick-threaded screw is for regulating the light by giving the carbons more or less immersion. Ribs and struts, like those of an umbrella, are loosely jointed to the rings C and E of this the domestic form of lantern, so as to hold it in the posision shown at Fig. 2, if in danger of being overturned.

All the varieties may readily be taken to pieces for cleaning: that shown in Fig. 1 by removing the two screws A and B, which allow the ring C to be taken off, thus releasing the carbons contained in the case D; and that shown in Figs. 2 and 3, by springing off the handle F, when the ribs and struts may be removed from the case. In both varieties the case is then free from all metal parts, and may be washed. The current is produced by a Trouvé battery, containing a saturated solution of bichromate of potash, such as that brought before the Académie des Sciences by M. Du Moncel, in March, 1883. The cover carries the carbons and the incandescent lamp, which, for preventing any chance of accident due to breakage is enclosed in a thick outer glass, that may contain water or any uninflammable and non-combustible gas, such as nitrogen. The

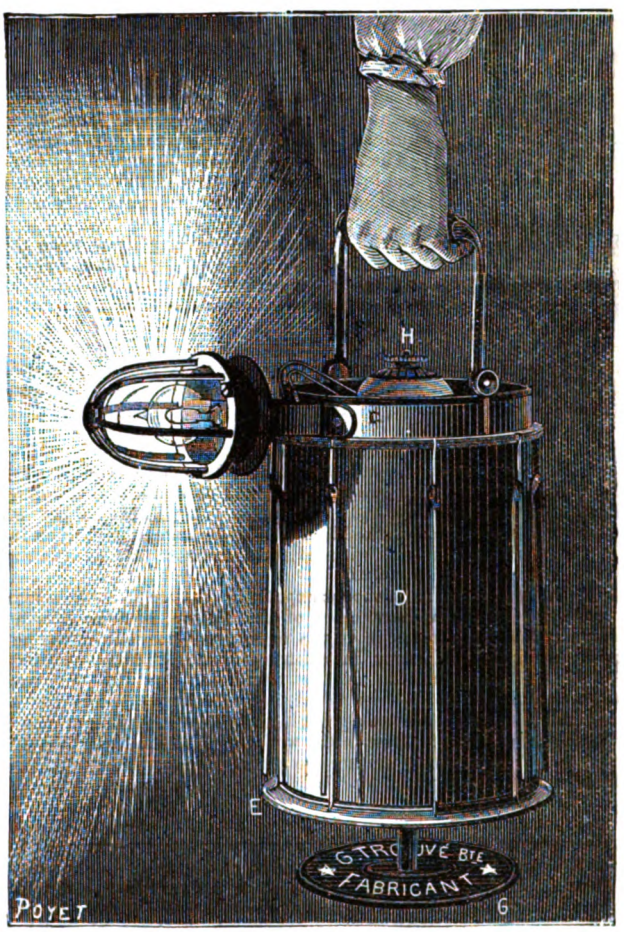

FIG. 3.

luminous intensity is that of four or five candles, or twelve to fifteen candles by combining two batteries with one suitable lamp; and the duration is about three hours of actual illumination.

These safe and portable lamps are useful for detecting leakages of gas, repairing gas mains and pipes, in fiery mines and distilleries—for all cases, in fact, where a light is necessary in a place where the atmosphere may be explosive. As a signal lamp that cannot be blown out, it should be invaluable on railways; while for domestic purposes it is always ready, consuming nothing until wanted, and dispensing with the searching for and striking of matches. Once more M. Trouvé has borne out his name and also his trade mark of εὕρηκα.

UTILISATION OF THE ISAR.—The Munich Electro-technic Commission has published a report on the utilisation of the power exerted by the River Isar. Of this power, estimated as being equal to that of 3,750 horses, it is proposed to retain 1,200 h.-p. for the electric lighting installations of the Municipality, and to let the remainder.

MR. CHAMBERLAIN ON THE ELECTRIC LIGHTING ACT.

On Thursday an influential deputation representing all those interested in electric lighting had an interview with Mr. Chamberlain (with whom was Mr. John Holms, M.P., and Mr. Calcraft), at the Board of Trade. The deputation consisted of Lord Thurlow, the Chairman of the Anglo-American Brush Electric Light Corporation, Sir Fred. Bramwell, Mr. J. S. Forbes, Lord Anson, Mr. R. E. Crompton, Mr. Robert Hammond, Mr. Offor, Sir Daniel Cooper, Mr. T. H. Cothill, Major Flood Page, Mr. P. Cremieu-Javal, Dr. Farquharson, M.P., and others.

Lord THURLOW, having briefly introduced the deputation, handed to Mr. Chamberlain the main points on which the Company sought an amendment of the Act. They were as follow :—(1) That the rights given to local authorities to purchase compulsorily electric lighting undertakings within their districts upon the terms set forth in section 27 of the Electric Lighting Act were such as to prohibit any supply of the electric light to the public, and such clause should be repealed. [This clause gives local authorities the power to purchase compulsorily the enterprise at the then valuation at the end of 21 years.] (2) In the provisional orders granted by the Board of Trade, under the Act, the provisions as to the compulsory laying down of mains should be omitted ; and the undertakers should have the full power to decide as to the position and extent of the mains to be laid down by them, and the right to compel the undertakers to supply them with the electric light should be confined to consumers willing to take a minimum quantity per annum. (3) The undertakers should be permitted to supply otherwise than by meter, and in such cases the purposes to which electricity is applied by the consumers should be matter for agreement between them and the undertakers.

Mr. CHAMBERLAIN said he did not want to put any stress upon them, but unfortunately a Cabinet Council had been called that day, and it was then sitting, and he was anxious to get back to it as soon as possible, and they would therefore be kind enough to make their observations brief, at the same time making them clear.

Lord THURLOW explained that the deputation Mr. Chamberlain had been kind enough to receive might be considered as fairly representative of all the leading if not all the electric light companies, and they were all united in the views to be expressed that day. He thought Sir Frederick Bramwell was anxious to express their views at some length.

Sir F. BRAMWELL said Lord Thurlow had made a mistake. He was not anxious to do so, he was anxious for some one else to do it. But as he had been called upon he would do so, and he would bear in mind the intimation Mr. Chamberlain had given them. He felt the subject was a very important one, and he should have liked to have dilated upon it.

Mr. CHAMBERLAIN did not wish to press them to say less than what they thought was necessary.

Sir F. BRAMWELL said he should explain in what capacity he appeared before them. He was a shareholder of the Edison, now the Edison and Swan Company. He was in it at the outset, and to that extent he was certainly an interested party in electric lighting. Moreover, he was consulted by many persons at the time that the Bill was passing through committee, and he was asked to give evidence before the committee, and he did so. He took great interest in the passing of the Bill, and he had taken great interest in the working of the Act ever since, and in that way it was that he ventured to state to them what he believed to be the views of the deputation. With respect to the importance of the subject, he thought it was undoubtedly a most important one. It was an illuminant now well known by its application to steamboats, and by private installations and theatrical installations ; and he thought it was agreed that wherever electric lighting was to be obtained—the glow system of lighting for domestic purposes—that it gave an amount of satisfaction which had only to be tested to be appreciated, and it was a lighting, for various considerations, to be desired if within the reach of those who wished to have it. He thought on sanitary grounds, on the question of the diminution of heat and the non-vitiation of air, on the grounds of the preservation of pictures, and books, and furniture, and the non-dirtying of walls and ceilings—on all these grounds it was most desirable. The ability to go into a room at any time without seeking for a lamp, and to press a button and forthwith light up the whole room was in itself no small matter. But he did not want to go into those details, but would take it that they were perfectly convinced that electric lighting was a desirable thing, and that many persons would be willing to pay for it if they had the means of having it. It could be obtained, no doubt, by independent installations, and was so obtained by many ; but there were objections to that, and what they wished was that the inhabitants could have it in lieu of gas—have it laid into their houses as gas and water were. Again, it was important in another point. It must be agreed that during the last fifty years the material progress of the world had benefited by the application of science, and he did not know a more important application of science than that of electric lighting. It was considered years ago to be impossible to divide an electric current to get light from different lamps. The thing was now done. Well then, again, at the present time, unhappily, there was great depression in trade, and a considerable want of employment among the working classes. There they had he believed a new outlet for their capital which would be spent in giving orders to factories which now want orders and employ artisans sorely in need of work. That was an important thing. There was another point, and that was this—our coal supply was a thing that we ought to husband and take good care of. It was not a question of cost, but a question of using coal. Let him put it to them that coal burnt under a steam engine to work a dynamo would give the same amount of light as one-third or one-fourth of the coal that would be needed for the ordinary luminant gas. He was speaking when used with glow lamps. When used with arc lamps the same light would be obtained with one-twentieth of the coal. When there was half a ton of coal used per annum per head of the population it became serious. The return in round figures was that 2,140,000 tons of coal was burnt in the metropolis last year. Upon all these grounds one was entitled to say that this was a subject of very great importance indeed. Up to 1882 many persons had hoped there would be a very rapid development of this mode of supplying light, and it would be by the application of private capital for public purposes that this would be obtained. He entertained that hope, and became a shareholder of the Edison Company to the extent of £5,000. When he knew the provisions of the Bill he for one thought them to be calculated to defeat the object of those who wished to see electric lighting spread. He had stated his views to the Committee, and he did what he could after the Bill passed to get the terms altered, but with no success to speak of, and the Act remains with Clause 27 in it of which he had to speak. He was aware it was difficult to get capital into new undertakings, and to get persons to take up new sources of light when they had their houses already fitted with the plant necessary for gas ; but in spite of that he believed, if a sufficient number of men able and willing to embark their capital, and to urge the matter, it might be without profit—to be pioneers of this mode of lighting—they would have done so had it not been for the provisions of this Act, which they were there to ask the Board of Trade to modify. As it was, he thought he was right in saying that these hopes had been entirely disappointed, and that there was now no provision in England—he did not know absolutely in England, but he believed practically none—for the distribution of light to the private consumers from central sources of supply. He would endeavour to point out how Section 27 had acted and must act to be a bar to all progress in the matter. The section was a long one, and after Mr. Chamberlain's intimation he did not wish to read it *in extenso*. He dared say the terms of it were within his (Mr. Chamberlain's) memory.

Mr. CHAMBERLAIN : Yes.

Sir F. BRAMWELL would summarise it in this way. Within twenty-one years, or in a less period, the local authority would have the option of the compulsory purchase of the undertaking, and they were to do it upon certain terms. They were not to pay anything in respect of compulsory purchase or goodwill or profits from undertakings, but they were to pay the value of all such lands, buildings, works, materials, and plant of such undertaking suitable to and used by them for the purpose of t ier undertaking within such jurisdiction, such value to be, in case of difference, determined by arbitration. The period was twenty-one years, and the earlier of those years must be passed in strenuous efforts to get the electric light taken up so as to pay working expenses ; and it did appear to him that it was impossible to induce capital to come into such an undertaking, after all these years of struggle have been gone through, if the local authority can come and purchase it if it pays, and if it does not pay the local authority does not. Then as regarded the terms. He would put it in this way. Supposing an electric undertaking was made by one of the local authorities themselves, they would, in the interests of the ratepayers, be compelled to deal with the matter in the way he spoke of. From the outset they were to come to a particular arrangement, and experience had shown if that arrangement was improved they would discard the original arrangement and take the new one ; but the company would not get one shilling of compensation. Further, it involved, as it appeared to him, the whole of the capital being called up at once. They would not under such a clause as that get an addition to a capital. Supposing they said that at the end of ten years a development had taken place, and there was need for new capital, no one would subscribe capital at that time with only eleven years left for the enjoyment of it. If it should be said the way to obviate that was to subscribe a large amount of capital and call up a portion of it, he would reply that no one would take shares. People would not embark money upon such onerous conditions as those. Let them remember that under the conditions of certain clauses persons in the district were entitled to call upon the company to give a supply. It was true they were bound to guarantee for three years a certain amount of capital, but still it would necessitate the undertakers finding new plant at the time the requisition was made. That might have to be found shortly before the expiration of the period, and under the circumstances no one would embark capital ; and it appeared to them that Clause 27 was one absolutely prohibitory to getting capital invested in that kind of undertaking. He might ask was it not desirable that the public should have the power of having within their houses the luminant in the same way as they obtained gas? He trusted on consideration the Board of Trade would see their way to repeal so much of the Act as was embraced within Section 27. He could have spoken at much more length, but after the intimation from Mr. Chamberlain he did not think it right to do so, and he asked him to supplement what he had left out.

Mr. CHAMBERLAIN said he had had some correspondence with some of the companies, and he asked whether Sir F. Bramwell spoke for all present when he asked for the repeal of this clause, but in some of the letters he had had the companies wanted a modification.

Sir F. BRAMWELL could not answer that. It might be that there were persons who did not expect they would get a repeal, but he put it that that was the fair thing to do. He was quite sure those gentlemen who asked for a modification would be too glad to have the repeal.

Lord THURLOW said there had been a meeting of the companies yesterday, and they had decided to ask for the total repeal of the clause, in the hope of getting a modification (laughter).

Sir F. BRAMWELL said he asked in common justice for a total repeal

Digitized by Google

of the clause in order that electric lighting should not be more heavily weighted than gas.

Mr. J. S. FORBES (the Chairman of the Edison and Swan Company) said those two companies had spent £380,000 in one way or another, and there was not only no return but there was not the remotest possible prospect of a return. He did not know what the Edison shares were worth, but the Swan shares, upon which £3 had been paid and on which £2 remained to be paid, he thought they would try and get something for taking them (laughter). They did not intend to go under that Act of Parliament, and they must at present give up all idea of public lighting. If Mr. Chamberlain wanted to kill electric lighting as applied to general lighting, then he would maintain the clause.

Mr. CROMPTON referred to Section 17 of Provisional Order for Redditch, which runs as follows:—"The undertakers shall within a period of two years after the commencement of this order lay down suitable and sufficient mains for the purpose of general supply upon the parallel system, in every street and part of a street specified in that part of Schedule A, and shall thereafter maintain the same." He said: It is my object, Sir, to point out to you that this obligation to lay mains over a fixed area has been a very principal bar to the carrying out of the provisional orders. Quite apart from the fact that the obtaining of these provisional orders being extremely costly, and is in itself a sufficient guarantee of the *bona fides* of the undertakers, I contend that this obligation entails a certainty of a heavy capital expenditure, which is extremely unlikely in the present state of the knowledge of the subject to prove remunerative. Since the passing of the Electric Lighting Act, and the granting of the Provisional Orders in the following year, our knowledge of the science of electric lighting has greatly advanced. We have had considerable experience in the fixing and working of detached sets of plant, but the fact that these sets of plants are detached, and that in this country, at all events, few or no public thoroughfares have had electric mains laid in them, has prevented us from increasing our stock and knowledge in the one respect which would have been of service to us in laying down these compulsory works in a satisfactory manner. There have been at least two modifications of the parallel system of main laying tried in America, and the data obtained have been very contradictory. Further, the conditions of supply in America differ from those in England, and at all events the American experience has so far been insufficient to enable us to choose a system of main laying which combines the three requirements of cheapness, efficiency, and durability. Thus far as to the laying of the mains themselves. Next, as to the districts in which the mains are to be laid. We find the very greatest difficulty in discovering who are likely to be our best customers in the future. In the case of provisional orders already granted, the obtaining of sites was of such paramount importance that the compulsory streets specified in Schedule A were chosen far more with regard to their nearness to the proposed site than with regard to their likelihood of furnishing a large percentage of paying customers. As time has gone on, it has been more and more forced upon us that the customers from whom we shall first obtain a revenue will be wealthy ones, and that they will be certainly for some time spread over a rather wide area. It follows that the obligation to spend a large portion of our capital in laying mains on certain fixed districts immediately contiguous to the supply station, and the hampering restriction as to extending these mains in any direction out of the A into the B district, will prevent us from laying the whole system in such manner as will give us the best chance of obtaining during the first few years of supply a remunerative return for our expenditure. Briefly, the two great objections to the laying down of compulsory works for electric mains are:—1st. That it would commit us to a large capital expenditure on a comparatively untried, and probably mechanically imperfect system; whereas at the beginning we wish to have the greatest possible scope to try several systems from which to choose the best to carry on our larger extensions, and that this compulsory laying on a considerable scale of what would very probably turn out to be a defective system would tend to increase the very evil from which the public are to be especially protected—viz., the frequent disturbance of the surface of the streets. 2nd. That the laying being made compulsory in certain fixed streets, or districts, is in all probability fatal to the chance of obtaining a remunerative revenue. I next beg to call your attention to the compulsory supply of electricity. Sec. 41 of the above Redditch Provisional Order, which states that the undertakers on being required so to do by the owner or occupier of any premises situate within twenty-five yards of the distributing main of the undertakers, shall give, and continue to give, a supply of electricity for such premises, subject to the provision of this order, and they shall furnish and lay any electric lines that may be necessary for the purpose of supplying the maximum current, &c. Now, Sir, I contend that this right to compel the undertakers to supply electricity should not be given to the consumers unless some adequate minimum of supply is fixed. As the section at present stands, the owner of a theatre, or any person giving any kind of exhibition or performance, requiring the use of a powerful light for a few minutes only during the whole 24 hours may compel the undertakers to furnish him with electricity sufficient for such display, and it is quite possible, and in fact very probable, to conceive a case where the capital cost to the undertakers of furnishing this supply for a few minutes per day may be thousands of pounds, as it would necessitate a large increase of the generating and distributing plant, whereas payment for this supply (being limited to the price obtainable under the order, viz., 8d. per unit as a maximum), might not exceed a few shillings. This is of course an extreme case, but the cases in which residents during a portion only of the year require a large supply of electricity during their shut term of residence in the district will be extremely common, and if any large number of such users have to be supplied it is certain that the undertaking will be rendered unremunerative. The experience gained during the last two years in working sets of detached plant has shown that the cases in which electricity has been produced most cheaply are those in which the hours have been long and the supply regular. I beg, therefore, to respectfully suggest that this section of the provisional orders should be amended by giving the right to compel the supply to such customers only as would use the light for at least 1,000 hours per annum.

Mr. HAMMOND also spoke.

Mr. CHAMBERLAIN said, in reply, that he was as anxious as the deputation for the development of this very important enterprise. He recognised the truth of all that Sir Frederick Bramwell had said on that part of the question, and if there was anything in the legislation of the past two years which unduly and unnecessarily interfered with it, he should be most happy to consider with them how that legislation was to be amended He understood their view to be put rather stongly before him that the small progress which had been made was entirely due to that legislation He did not want to enter upon contentious subjects, or he could argue that a little. He should say that in a great measure the failure to proceed more rapidly was owing to the haste on the part of companies which have been more or less financial speculations. A few years ago those companies came to Parliament and proposed practically to parcel out the whole of the kingdom among them at a time, according to the statements just made, when they knew so little of the matter that they did not know the best form for giving the supply; that they did not know the best form of dynamo; that what they purchased for £2,000 turned out a few months afterwards to be only worth £200; and generally the whole matter was in an empirical condition which could not form the basis for really sound commercial enterprise. Under such circumstances it seemed to him it was the duty of Parliament to prevent the appropriation of all the avenues to this great business by companies and individuals who were not really prepared to deal with it in a practical way. A Committee of the House of Commons was appointed for the purpose of considering the whole matter. He thought the Committee would be generally admitted to have been a very able and impartial committee, upon which all interests and a great deal of the existing knowledge was thoroughly represented. Mr. Stanhope was the chairman of that Committee, which came practically to a unanimous conclusion, and the Act now complained of was the result of its deliberations. What was the intention of the Committee in proposing the Bill, which was subsequently somewhat amended in the House of Lords, on the motion of Lord Bramwell and other gentlemen interested in the matter? The Bill, as it left the Commons, gave only fifteen years before the right of purchase arose; but in the House of Lords twenty-one years was substituted for the fifteen. The Committee's intention undoubtedly was to prevent the creation of those vast monopolies which in the case of gas and water had sprung up, and which were believed by at any rate the majority of the people to be on the whole inconsistent with the true advantage of the community. At the same time the object was not necessarily to interfere with the progress of this industry. Sir F. Bramwell said it was very hard that this business which comes into competition with gas should be subject to limitations which are not applied in the case of gas. But he omitted altogether to state that gas was under considerable limitations. In the case of gas there was no attempt made to prevent a monopoly; but there was an attempt made to limit the monopoly in the interest of the community by having limitations of dividends, which experience had shown did not work very well; but the object was the same in the case of gas as in the case of electricity, although it was sought to be obtained by different means. Several speakers had said there was no similar case of restrictions such as those which appeared in the Electric Lighting Bill. That was also a mistake, because there was precisely the same restriction in the case of tramways. With the same view in the Tramways Act there is a clause which enables the local authority to purchase at the expiry of twenty-one years. The object was exactly the same, even if the detail of the method be somewhat different. He would admit at once that if they were to discuss the methods they were fairly open to reconsideration. He should say that in the 27th clause the object of the Committee was that, while the community should be enabled to resume this monopoly at any moment after the twenty-one years, it should do so on terms which would at all events fairly recoup the undertakers for all legitimate outlay. It might be that the terms of that clause did not carry out that object, and if the deputation were of that opinion he could only say that if they would draw up such a modification of the clause as in their opinion would satisfy those conditions, he would take care that it had the fullest consideration. But he was bound to say frankly that he could not give any support whatever to a plain proposal that the whole of that clause should be repealed. He did not think that the local authorities of the country would assent to any proposition of that kind, and he could not think that Parliament, which had shown itself hostile to the creation of those great monopolies, would allow a new one in the case of electric lighting, unguarded by any such limitations as those which they had sought to impose. Some kind of limitation they must take to be an absolute necessity; and the only question to consider was whether the limitation imposed was a limitation which unfairly restricted the progress of the industry, and which therefore might be properly altered as to its details. There were a number of minor matters which he admitted were subjects for further consideration, and upon which he should be very glad to have any propositions from the deputation. In the first place, there was the question of compulsory supply to a district. Mr. Hammond said that the concession was not a monopoly. It was not a legal monopoly, but it was a practical monopoly, because there was no doubt that the Board of Trade would not grant an alternative concession except upon proof that the existing concessionaries were not properly performing their duty, or that some great improvement had been made, and that they were not satisfactorily dealing with the matter. Therefore it was a practical monopoly, and a practical monopoly must carry with it corresponding obligations. The obligations may be a little too stringent for the present condition of this invention. If so he

Digitized by Google

should be glad to know the exact measure in which they wanted them modified. But to say that they should give to a company what was practically the absolute control of a large district without any obligation at all, enabling them to shut out other competitors who might be willing to do more, and to do nothing themselves, was a proposition which must not be entertained. Some kind of obligation there must be, and the question was to what extent it must go. The second point was that where mains are laid down they were under a condition to supply compulsorily all consumers. But they omitted to say that it was only under certain circumstances. That was of some importance, because the question had been brought before the Board as to whether it might not be desirable that supply should be given to certain *quasi* public institutions, like clubs and institutions of that kind, where a very large quantity would be taken without a necessary obligation to supply private consumers. There was nothing in the provisional orders which would prevent an arrangement of that kind. Neither was there anything in the Act or provisional orders which would prevent the differential price in favour of large consumers. That differential price existed no doubt in the case of gas, and he saw nothing unjust in it—nothing to prevent a similar arrangement in the case of electric lighting. Upon that matter, therefore, if any practical proposition were placed before the Board, they would be glad to facilitate the supply of electricity in particular cases without enforcing too stringent and too general an obligation. It was suggested they ought to have the right of compulsory acquisition of land for works. That appeared to be a perfectly reasonable application, and one he would be glad to give effect to. As to the delay in granting provisional orders, he might point out that a license could be obtained at almost a single notice.

Mr. HAMMOND: Only for seven years.

Mr. CHAMBERLAIN said that was so, but it would give them rights for the moment, and cover the period which would be taken up for a provisional order. The provisional order might subsequently be substituted for the licence, and in the meantime their rights would be protected by the rights previously obtained by the licence. If possible he would not allow any technical difficulty or any red tape to stand in the way of expediting those things if they showed how those things could be done. Then as to the question of constant supply, he thought that the obligations of the Act had been somewhat misunderstood. He did not understand that the obligation was absolute. If a constant supply was not given he understood that the undertakers would be liable to a fine; but it would be open to them to show reason why they had been unable to comply with the obligation to give a constant supply. In that case they would be released from the fine, or it would be purely nominal. He did not think that there was anything there which constituted a practical danger or a risk which would seriously interfere with their proceedings. The last point was a point upon which he agreed with them entirely in principle, although nothing had been said as to the way to give it effect. He was quite willing to give greater power to the local authority. He did not like the difficulty now cast upon him, and he would like a modified form of Home Rule, so that the local authorities would be able to deal with each case in the manner they thought right for the interests of their locality. The practical conclusion of the whole matter was this—that while he could not give any hope that he would favour the repeal of the 27th clause, he would give the best consideration to the form of clause—he should like it drawn in the form of a clause—which they might send him, for either modifying that clause in the Act or the orders to which they objected.

After some further conversation the deputation withdrew.

PARLIAMENTARY NOTICES FOR NEXT SESSION.

In the ensuing Session of Parliament the United Telephone Company notify their intention of applying for an Act authorising them, or the Company, to be incorporated by the intended Act, or their agents, licensees, or other persons "To lay down, suspend, place, erect, and maintain, and at all reasonable times to have access to, pipes, wires, posts, pillars, insulators, conductors, and other works and apparatus connected therewith, in, through, across, along, under and over, highways, streets, roads, lanes, passages, footways, and other places, tramways, railways, canals, docks, basins, waters, rivers, bridges, houses, works, and other buildings within 100 miles of the General Post Office, within the Parish of St. Martin's-le-Grand, in the City of London, and for such purposes temporarily to break up, open, or otherwise interfere with," such highways and other places and properties before enumerated, and also any sewers, drains, water or gas mains and pipes, and all other works in, over, or under such highways or other places and properties "as may be necessary or convenient for the full and efficient formation and maintenance of telephonic communication, subject to such conditions, restrictions, and regulations as may from time to time be prescribed by the Board of Trade or other public authority, or otherwise as shall be provided by the intended Act."

The Act will contain clauses to authorise the Company or the new Company to purchase and take upon lease or otherwise such lands, premises, &c., as may be necessary or expedient for offices, stations, or otherwise to enable the Company to carry out the purposes of the Act. Powers will also be asked for to authorise the Company or the new Company on the one hand, and all corporations, vestries, local and other boards and other public bodies and all railway, canal, and other companies within the limits aforesaid, on the other hand, to enter into and carry out agreements for facilitating telephonic communication. Authority will be asked enabling "the Company or the new Company, for the purposes of the intended Act, to acquire, sell, manufacture under, or otherwise use any patents and licenses for the transmission of telephonic communication, and also to grant licenses to manufacture under, or use any such patents either within or without the limits aforesaid." It is stated that "the powers and provisions of the intended Act will be either conferred upon, or be made applicable to, the Company as at present constituted, or if found necessary or desirable the Company will be dissolved and the shareholders therein re-incorporated, either with or without other persons or bodies as may be provided by the intended Act."

The Charing-cross and Waterloo Electric Railway Company will apply for leave to bring in a Bill authorising them to construct an extension of the railway to Cockspur-street—commencing at Charing-cross, about 85 yards west of the statue of King Charles I., and terminating by a junction with the commencement of the railway authorised by the Charing-cross and Waterloo Electric Railway Act, 1882. Further powers will be sought as to the compulsory purchase of lands, and as to tolls and underpinning; while an extension of time for the compulsory purchase of lands and buildings, and the construction and completion of the railway authorised by the Act of 1882, will also be asked for. By another application the company intend to ask for leave to bring in a Bill authorising the abandonment of the railway and works sanctioned by the Charing-cross and Waterloo Railway Act, 1882, and to release them from all liabilities, penalties, and obligations in respect of their completion.

The Incandescent Electric Lighting Company (Limited) will apply for leave to bring in a Bill to extend the time limited by the Birmingham Electric Lighting Order, 1883, within which the local authority may require the company to sell their undertaking for such period, and, if need be, to alter the terms and conditions of such sale in such manner as the Bill may define or Parliament may sanction, and to extend the period within which the Company are to lay down the works mentioned in the Order. Powers are asked to alter and lessen the compulsory works which the Company are by the Order required to lay down, and to define these works, or to relieve the Company from laying them down, and to make other provisions in lieu thereof; and authority is also sought to enable the Company, on the one hand, and the Corporation of Birmingham on the other hand, to enter into agreements with reference to the matters mentioned in this notice, and to confirm any contracts which have been or may be made touching any of such matters. Power is also sought to alter, extend, or repeal, so far as may be requisite or desirable for the purposes of the Bill, all or some of the provisions of the Order, and of the Electric Lighting Act, 1882; and provision is further made for the dissolution and re-incorporation of the Company.

NOTES.

TELEGRAPH CABLE INTERRUPTED.—The cable between Fao and Bushire is interrupted.

DEATH OF M. CALLAND.—M. Calland, well-known on the Continent as the inventor of a battery largely used in telegraphy, is dead.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 21st Nov. amounted to £4,781.

RAILWAY LIGHTING IN AMERICA.—We learn that a Woodhouse and Rawson electric lamp has been applied to the lighting of a car on one of the Massachusetts railways.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts for the week ended 21st Nov., 1884, were £3,789, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

RUSSIA IN THE EAST.—A St. Petersburg telegram, through Reuter's agency, dated Nov. 25, states that the Ministry of War has decided upon the immediate construction of a telegraph line from Askabad to Merv, *viâ* Anno, Babadurma, Bugatchik, Artchingan, and Sarakhs.

EARTHQUAKE IN THE UNITED STATES.—A Reuter's telegram, dated New York, Nov. 24, states that two shocks of earthquake have occurred at Concord and were also felt in other parts of New Hampshire. The second shock was more severe than the first, and shook the buildings of the city.

GENERAL TELEPHONE COMPANY.—The new general manager of the Société Générale des Téléphones, in place of M. Latigue, whose death we recorded last week, is M. Richard, an administrator (or director) of the company, formerly engineer for the Paris telegraph service, and now manager of the Bezons works.

INTENSE CURRENTS.—The President of the French Republic has appointed a commission, presided over by the Minister of Posts and Telegraphs, for drawing up a special set of regulations, fixing the technical conditions to be complied with for preventing danger to the public from electric leads for light or power.

TELEGRAPH TO ABERFOYLE.—It is probable that the North British Railway Company will soon open telegraph offices at Aberfoyle and at New Killearn Railway Station, a boon which will be greatly appreciated by the public, especially in the case of Aberfoyle, hitherto six to seven miles from the nearest telegraph office.

ELECTRICITY IN NEW YORK.—The *Standard's* N.Y. correspondent telegraphs that it has been decided to employ electric motors on the Brooklyn Bridge within sixty days, and upon the Elevated Railways within ninety days. The inventors have pooled their interests and united in the working of their patents. The result promises to be a rapid development of locomotion by the aid of electricity.

RED TAPE IN THE TELEGRAPH DEPARTMENT.—We have encountered a piece of obstruction in the telegraph administration that calls for a remedy. We had occasion to request some information by telegraph, and wished to leave a sufficient deposit to cover a long reply. But we were informed that no more than 2s. for a reply of forty words could be prepaid, and that this only applied to an ordinary telegram, not to what are known as "press telegrams" at a reduced rate.

TEMPORARY LIGHTING.—On the 18th inst., on the occasion of an "At Home," given at Surrey House by Mrs. Horniman, the reception rooms and adjoining museum were brilliantly illuminated by an installation of the electric light by means of incandescent lamps. The current for these was supplied by storage batteries, which were sent from the Electrical Power Storage Company's works at Millwall, ready charged. The lamps were of 50 volt 20 candle-power; and the method adopted ensures a perfectly steady light.

PARIS ELECTRICAL EXHIBITION, 1885.—The Société Internationale des Electriciens, desirous of contributing by all the means in its power to the development of electrical science, has decided that an exhibition shall be held in January, 1885, on the occasion of its first general assembly. The object of this exhibition is, not merely to bring into prominent notice new appliances, and to bring together the discoveries and improvements made up to date, but also to sum up the progress made, by means of lectures given by the most illustrious *savans* and the most eminent electricians.

ELECTRICITY IN SPAIN.—The Spanish Minister of Marine has entrusted the Sociedad Española de Electricidad with supplying all the electrical accessories required for the arsenals and men-of-war, especially for the electric lighting of the latter. This company has also lighted with arc lamps three war vessels, the "Victoria," the "Numancia," and the "Sagunto." The shops of the Maquinista Terrestre y Maritima Company at Barcelona are lighted by 32 arc and 20 incandescent lamps, while those of Fiol y Vives, at Centillas, have been fitted with 80 incandescent lamps.

ST. PETERSBURG TELEGRAPH CONFERENCE.—At a meeting of the Board of Directors of the Manchester Chamber of Commerce on Wednesday, a letter was read from the General Post Office, stating that the Department has no intention of proposing at the approaching International Telegraph Conference any restrictions with regard to the regulations applicable to telegraph code messages, and that no reduction in the number of letters allowed as the length of a code word was in contemplation. Indeed, the Department would oppose any such alteration if proposed by any other administration.

ELECTRIC LIGHTING OF STREETS.—The Streets Committee of the Commissioners of Sewers visited Norwich last week to see the electric lighting arrangements at Messrs. Colman's works. The lighting was pronounced to be satisfactory; and it is understood that a recommendation will be made that some of the Metropolitan streets be lighted in a similar manner. We suggest that, if the lighting is to be satisfactory, it be given to some responsible firm, and not to the "lowest or other tender." The obtaining of orders at any price has proved disastrous enough already, and if the public ask for a good light they should not object to pay for it.

CABLE IN THE ARLBERG TUNNEL.—The telegraph cable, lately laid in the Arlberg Tunnel, consists of twelve strands, of which half are reserved for the Government service and three for that of the railway, leaving three for eventualities. Each strand is formed of seven copper wires, twisted and enclosed in gutta percha, while the covering consists of tarred hemp and eighteen galvanized iron wires, twisted round which is rolled a band of tarred cotton. At each end of the cable, outside the tunnel, lightning conductors have been put up with a good earth connection, with the object of protecting the cable from any violent discharge of atmospheric electricity.

NEW POST OFFICE FOR BRADFORD.—In the new Post Office for Bradford, designed by Mr. Henry Tanner, of H.M. Board

Digitized by Google

of Works, Leeds, and which is shortly to be commenced by Messrs. J. and W. Beanland, contractors, of that town, the public room will have more than 60ft. of counter space. The first floor of the building will be devoted exclusively to the telegraphic department. The instrument room will extend over the whole of the public hall and entrance lobbies, the telephone room being over the private letter box department; and over the inquiry, messengers', and other offices will be the superintendent's office and a room for the use of lady operators. On the second floor there will be rooms set apart for line men, mechanics, and batteries, and also for the curator.

NEW COMBINATION COMPANY.—The *Standard's* New York correspondent telegraphs that the agents of the Daft, Edison, Siemens, Brush, and Field electric motors have organised a company, with a capital of one million, half in cash, and the balance represented by patents to be distributed among the five original companies, in proportion to their relative merits, according to the judgment of Professors Sir W. Thomson and C. R. Cross, and the Presidents of the New York Central, the Pennsylvania, and the Northern Pacific Railways. These gentlemen may even award the entire half million to a single motor. The new company thus becomes the sole owner of everything at present known to be valuable in connection with electric locomotion. Its promoters are sanguine of being able to produce, within ninety days, a system that shall be applicable throughout the world.

ELECTRIC LIGHT IN GLASGOW.—The bazaar which opened in the St. Andrew's Halls on Wednesday is illuminated electrically, Prof. Jamieson, Principal of the Science and Art College, acting as hon. consulting electrician. The arrangements were carried out, under the direction of Mr. J. Law Crawford, electrician and medallist in electric lighting, by Messrs. Anderson and Munro, electrical engineers, Glasgow. There are eight Pilsen arc lamps, suspended in two groups of three each from the ceiling of the large hall, with two single arc lamps on high Venetian masts. The arc lamps are specially suitable in this case, as they are arranged so as to throw into shade the architectural features of the hall, which contrast badly with the decorations. The stalls are brightly lighted by 250 incandescent Swan and Pilsen lamps. The arc lamps are supplied with current from a Pilsen dynamo, and the incandescents from a Victoria Brush dynamo.

ELECTRIC LIGHT IN GRAVING DOCKS.—The Port of Havre, which was in 1881 fitted with the electric light, for permitting of loading and unloading vessels by day as well as by night, has now adopted this method of lighting for its graving docks. Three Gramme regulators, the height of which can be altered with decagonal reflectors, are provided for each quay, the current being led by overhead wires on ordinary telegraph posts. Two F Gramme dynamos, with a special engine, are placed in the building which contains the pumping engines for emptying the docks. Each dynamo supplies two circuits, each with three lamps, while a switch near each lamp permits of turning its current on or off. The two smaller graving docks of the Citadel Basin are lighted by four Gramme regulators similarly arranged; but as they adjoin one another, the lamps are placed so that their light may be thrown on one or the other, or on both, at pleasure. The plant was put down by Sautter and Lemonnier, of Paris.

ELECTRICITY AND CHOLERA.—In the *Daily News* of the 21st inst. there appeared an excellent article describing a visit paid by the writer to the Cholera Hospitals of Paris. At one of them he was told by Dr. Peters, the physician in charge of the cholera patients, that he had been trying both continuous currents and ice, and that though the use of the latter had been attended with the best effects, yet electricity also had done good work. It appears that electricity was tried some years back as a preventive of cholera, for in a book by the late Mr. Alfred Smee, F.R.S., entitled "Elements of Electro-Biology," and printed in 1849, the writer mentions that the alimentary canal is very easily affected by a current of electricity, and continues:—"I have heard that electricity has been advantageously employed at the Free Hospital to rally a patient in the collapsed stage of cholera—a fact which I mention here, as this disease involves to a great extent the functions of the alimentary canal."

CAUTION TO INVENTORS.—We are informed that, at the meeting of the Inventors' Institute on Monday evening last, Mr. J. S. Beeman drew attention to the question whether or not any special action should be taken by the institute to warn inventors against the risk they will run through exhibiting anything for which they have obtained provisional protection, or for which they have taken the necessary steps for so doing, at the forthcoming Inventors' Exhibition, while the Patent Office pursues its present course. He showed how under Section 7 Clause 1 of the Patent Act, 1883, anyone can take out, prior to the opening of the exhibition, a "bogus" patent by lodging a provisional which no one could understand, and which must necessarily be sent back for a clearer definition or drawings, and that the intending patentee had then about nine months' grace before he need send in his clearer definition, during which time he could be hunting all round the world for other people's brains. If this is as Mr. Beeman pointed out, surely it is deserving of immediate action.

ELECTRIC LIGHT IN SAW MILLS.—Mr. J. C. Howell, of Llanelly, under whose superintendence the electric light was applied to Messrs. Morewood and Co.'s South Wales Tin Works about two years ago, has now put down an incandescent plant at Messrs. Howell and Son's saw mills. The Swan lamps for the offices are placed in movable fittings, which are very convenient. In the laboratory is a self-regulating Crompton-Bürgin dynamo, capable of maintaining seventy-five 20-candle incandescent lamps. Accumulators supply current to the lamps when the engine is not working. The laboratory is generally lighted by six lamps, but as many as a hundred may be turned on when required for experiments. Twenty-four lamps are distributed about the mills, being, as a rule, placed over the benches, but they may be drawn down close to the work, brought underneath the benches, or moved about wherever required. Mr. Howell computes that, at Llanelly, for 1,100 hours of lighting per annum, electric light costs about the same as gas, while for 3,000 hours it is 50 per cent. cheaper.

ELECTRIC LIGHTING ACT.—We are glad to hear that immediate action is to be taken upon the suggestions of Mr. Chamberlain to the deputation reported in our last issue. It is considered very advisable that the suggestion made by the President of the Board of Trade, that the companies should submit, for the consideration of the Board of Trade, clauses embodying the desired modifications of the Act and Provisional Orders, should be acted upon without unnecessary loss of time, and a general opinion having been expressed that a committee consisting of representatives of the various electric lighting interests should be constituted to draw up such clauses and to confer with the Board of Trade. Lord Thurlow, as having introduced the deputation, has taken in hand the formation of an influential committee, which will be as representative as possible, and after having carefully considered the

Digitized by Google

whole question will collectively submit the conclusions arrived at to the President of the Board of Trade. The Anglo-Brush Company is taking an active part in the formation of this committee, in continuation of its efforts towards the modification of the Act.

THE POST OFFICE AND THE TELEPHONE COMPANIES.—The following important communication was posted up in the Stock Exchange on Monday:—"24th November, 1884. Dear Sir: I am requested by my Board to acquaint you that the new form of licence for this company has been to-day received from the Postmaster-General. The licence is for 31 years from the 1st of January, 1881, and the following are the principal points on which concessions have been made:—The licence contains no limit of area nor restriction as to running trunk wires from town to town. Call offices may now be opened, whereby members of the public can communicate with subscribers. The claims of the Post Office to provide in the licence for the supply of telephones to the Department by the company, and the proposal that the company should pay a royalty to Government upon private wires erected and maintained by it, have been given up. By a separate agreement telephone exchanges may be connected with the Post Office, and subscribers may send and receive telegrams by telephone. I am, dear sir, yours faithfully, Thomas Blaikie, secretary. Henry Charles Burdett, Esq., Share and Loan Department, Stock Exchange, E.C."

ELECTRIC LIGHT AT TEMESVAR.—The *Standard's* Vienna correspondent telegraphed that Temesvar, in Hungary, the first European town where the electric light had totally superseded gaslight, was on Saturday and Sunday nights left in complete darkness. Since its installation at the beginning of the present month, the electric light had worked exceedingly well, and a number of foreign experts had just arrived to witness its triumph, when suddenly the whole arrangement failed. The experts believe that a severe snowstorm had disarranged the wires, but the latest telegrams say that the pumping machines working the dynamos are out of order. The real cause is that the River Bega, which supplies the pumps, was frozen over; but this difficulty is being remedied. The moral of this little *contretemps* is that all electrical plant should be duplicated, so that an accident may not cause entire failure. Especially should precautions be taken to prevent the motive power from giving out. Again, gas is not consumed directly as made, but is stored up. Just in the same way, electric current should not "live from hand to mouth," as it were, but have something to fall back upon. Our account of lighting trains on the Brighton line shows one way in which this difficulty may be avoided.

INCANDESCENT LAMPS V. BLUE DEVILS.—"I recommend light as an improver of animal spirits," said Sydney Smith. "How is it possible to be happy with two mould candles, ill snuffed? You may be virtuous, and wise, and good, but two candles will not do for animal spirits. Every night, the room in which I sit is lighted up like a town after a great naval victory, and in this cereous galaxy, and with a blazing fire, it is scarcely possible to be low-spirited; a thousand pleasing images spring up in the mind, and I can see the little blue demons scampering off like parish boys pursued by the beadle." If a "cereous galaxy" could have such an effect upon the writer, what would he have said of a galaxy of incandescent lamps. It is true that the same inspiriting effect may be had by turning on all the available gas burners in the room, but for how long? The "little blue demons" which have scampered off at the sudden blaze of light presently return, the breathing of the occupant of the room is oppressed, his head feels heavy, the eyes smart and ache, and by and by the ultramarine ones of the long tails reign supreme. His last state is worse than the first. Incandescent lamps are the only true dispersers of blue devils, and may they—the lamps, not the last mentioned—soon be within the reach of everyone.

THE LATE MR. FAWCETT.—Communications having been addressed to head-quarters, says the *Post Office Circular*, not only by individual officers, but also by offices collectively, suggesting that steps should be taken with a view to perpetuate the memory of the late Postmaster-General, the secretary is anxious to learn whether the desire thus expressed is so far general throughout the service as to justify its serious consideration. He therefore requests that heads of departments, postmasters, and others in a position to do so, will be good enough to ascertain whether there is among the officers under their control a spontaneous and general desire to join in any movement having for its object the commemoration in a suitable manner of the connection of Mr. Fawcett with the Post Office. As the value of such a movement will depend upon the spontaneousness of its character, the secretary thinks that the feeling of the Department will be best ascertained by the publication of this notice, and by its being left to the different branches of the service to take such steps as they consider desirable to represent their wishes to superior officers. All communications on the subject should be addressed to the Secretary, General Post Office, London, with the words "Fawcett Memorial" inscribed in the left-hand corner.

THE ELECTRIC LIGHTING ACT.—Commenting on the interview between Mr. Chamberlain and the representatives of the electric lighting interests, last week, the *Pall Mall Gazette* remarks:—"The electric lighting interests got some comfort from Mr. Chamberlain, and probably as much as they expected under the circumstances. With one voice they demanded the repeal of the 27th clause, which gives the local authorities powers of compulsory purchase after twenty-one years. Mr. Chamberlain as promptly replied that he could not consider such a proposal, but he invited the companies to draw up a clause embodying their views of what they thought reasonable. Mr. Forbes emphatically declared that, although there were many who were ready to stake their thousands in the enterprise, no one would do so with such a limitation as that contained in the 27th clause. If the companies are wise and diplomatic in availing themselves of Mr. Chamberlain's offer, they may now get a fair modification of the Act; but little is to be gained by an out-and-out extreme demand for the absolute freedom of action and entire freedom from all corresponding obligation made by Mr. Crompton. To grant such a request would be to relinquish at once the power to prevent the establishment of another domineering monopoly like that of the water companies. It would be a rash Government that would dare to assent to anything of the sort. But the matter may be very well arranged by giving the electric lighting companies a longer lease of life—say, thirty years instead of twenty-one."

NEW BATTERY FOR LIGHTING.—On the occasion of the Queen's leaving Balmoral, on Wednesday, the Royal dining room at Perth was lighted by Swan lamps in pink shades, supplied by current from a new battery, the joint invention of a French chemist, M. de Lelande, and Mr. Berger Spence, of Manchester and London. The battery is formed by immersing a zinc plate in a cell formed by an ordinary iron dripping pan containing a layer of oxide of copper and a solution of caustic potash or soda, and placing a number of these pans or cells in circuit, being isolated from one another by glass insulators. The battery on this occasion was formed

Digitized by Google

by sixty of these cells placed in a retiring room, and the wires were connected with two elegant candelabra placed among the flowers on the dining room table. Each of the latter held three wax candles, through the centre of which the wires were passed, being tempered by pink coloured shades which enclosed them. Her Majesty was so charmed, on entering the room, as to give way to involuntary expressions of pleasurable surprise; and in the course of her stay she made a personal examination of the apparatus. The whole of the arrangements were superintended by Mr. C. E. Boothby, civil engineer, Springfield, Cupar, and Mr. John Home, W.S., Edinburgh. We learn that a syndicate has acquired the exclusive right to the patent for the whole of Scotland, and Mr. Home, on their behalf, is at present engaged arranging for the formation of companies in each county. A company has already been formed in Mid-Lothian with an influential board of directors.

Health and Electric Light.—Mr. Ernest Hart, in a paper on the Health Exhibition, read before the Society of Arts on Wednesday evening, observed that it was no small thing to have acquired the conviction that our open spaces may be, and should be, much more largely devoted to the open-air recreation of the people than they are at the present moment; and he continued:—"Within an arrow's flight of the houses probably of most of us who are here there lie great open spaces, such as Hyde Park (but what I say refers also to Victoria Park), which at night are dreary, desolate areas of darkness, which are unlighted, which are dangerous to cross, which are unused in the evenings for any wholesome or moral purpose, which are often scenes for the display of some of the worst vices incidental to the lowest dregs of the population of the great city. Why should we not learn from the success of the music and the lighting of the gardens of the Health Exhibition that our great parks should all be lighted by the electric light at night, and that throughout the spring and summer months the military bands should play there, and should make those places, which are now not only useless but scandals to the metropolis the sites of healthful and innocent recreation. I have inquired from a good source what would be the cost of lighting Hyde Park by the electric light; and I am not speaking without data when I say that I believe Hyde Park could be adequately lighted with the electric light, so that it might add to the resources of health and enjoyment for the teeming population surrounding it, at an annual expenditure of about £5,000."

Conversazione of the National Telephone Company.—On Wednesday night the National Telephone Company held their fourth annual *conversazione* in the Victoria Halls, West Regent-street. A large number of the *employés* and their friends assembled, and there were present, among many others, Professor W. Bottomley, Mr. F. F. Begg, Edinburgh, District Superintendents Millar of Aberdeen and Lumley of Dundee, and Mr. W. A. Smith, director, who occupied the position of chairman. In the course of the evening the chairman delivered a short address, in which he expressed the pleasure he had in being present. Referring to the progress of the company, he said that the number of people who had benefited by their labours were increased by a hundredfold, while their revenue had increased by a hundred per cent. In consequence of the liberal concessions made by the late Postmaster-General it was possible, and indeed in a short time it would be an accomplished fact, that all villages of any importance would be connected with each other by telephone. He also spoke of the useful inventions of two members of their company, namely, Messrs. Bennet and Sinclair. The former had invented an induction coil, by which they were enabled to communicate with outlying towns without running a double line of wires, and also a battery which had been successful in the hands of some. The latter was the originator of the automatic switch—one of the greatest strides that has been made in telephone work. As a matter of interest, he mentioned that the number of calls in the National Telephone system alone for the last month amounted to 684,000. During the evening dancing was carried on with zeal, and was occasionally varied by intervals of songs and music.

Compound Dynamos.—In an article on the use of compound dynamos for maintaining incandescent lamps, the *Zeitschrift für Elektrotechnik* contends that the differences of potential at the terminals does not remain constant, so as to dispense with a regulator. Our contemporary continues as follows:—"In fact, an installation of incandescent lamps cannot be regarded as satisfactory unless they last for 800 or 1,000 hours; but, to obtain this result each lamp must not be subject to variations greater than 1 per cent. of its normal potential. Now such a constancy cannot be ensured without a regulator, even with the compounds, for if the intensity of the current vary 20 per cent. the difference at the poles will vary about 3 per cent. A good shunt dynamo (an Edison for instance) gives almost as satisfactory results, since the intensity, increasing by 10 per cent. the difference of potential at the terminals only increases by 1 per cent. and 4 per cent. for an increased intensity of 25 per cent. But there are causes of irregularity still more unfavourable to the constancy of the difference of potential at the terminals, than are the variations in speed of the engine, which more often than not attains as much as 5 per cent., causing similar discrepancies in the difference of potential at the terminals; and no plant is so carefully put down from a mechanical point of view that the driver can answer for a constancy in the number of revolutions of his engine without a governor. The losses of pressure in the conductors are a third source of variation in the difference of potential. A plant may, in fact, be considered to be put down under good conditions for which a loss on this head of only 10 per cent. is reckoned; that is to say, 8 per cent. for the principal conductors and 2 per cent. for the shunt circuits maintaining the lamps. If, then, a group of lamps be switched off, and the intensity be reduced by one-half, the resistance of the main conductor is just so much reduced; and the lamps which remain in incandescence work under a tension 4 per cent. greater. Lastly, there is a fourth cause of inconstancy, which is the heating of the dynamos. For if, some time after starting, the resistance of the machine be modified in consequence of the heating of the conductors, there also follows a modification in the difference of potential to which the combinations of the best designed compounds can offer no remedy. In fact, in all installations with compounds, it is always found necessary to add a regulator sooner or later. But in that case, if a regulator be required, as with a simple dynamo, of what advantage is the compound? Is the useful effect greater? No! for at recent exhibitions it was the shunt-dynamos which gave the best results. Are sparks more easily avoided? That is not proved. On the other hand, compounds have an incontestable disadvantage, which is that, in short circuit, the conductor of the induced current often burns notwithstanding the best cut-outs, while with the shunt-dynamos there is only a lessening of intensity."

Edison's Lighting Station in New York.—We have from time to time given particulars of the central station established by Edison in New York, and opened in September, 1882. But we find in the *Statist* a comprehensive account,

Digitized by Google

from which the following abstract is made:—The space lighted is contained in a square of 2,400ft., and has, therefore, an area of something less than a quarter of a square mile. The district contains about 50 blocks of buildings, and is intersected by some 15 streets or passages. The necessary permission to open the streets to lay the electric mains was obtained, not by Act of Congress or by other legislative or official means, but by the simpler and perhaps less costly method of a payment of about £10,000 to Tammany, and in exchange for this payment the Edison Company is free to take up the streets when necessary for electric lighting purposes. On 4th September, 1882, the station was started with 2,323 lamps, contained in about 85 houses, and these increased in number until 12,540 lamps were installed, the present capacity of the station being now attained. The largest number of lamps ever burning at one time was 5,530, in January of this year, and their average life, based on about 12,000 renewals, is a little more than 400 hours. Shortly after the installation of the station it was found that some of the customers did not require the light in the summer, and that consequently their custom involved loss. It became necessary, therefore, to cull from among the customers those whose demand was less than an average of $2\frac{3}{4}$ hours per day for every lamp connected on their premises. If their consumption fell short of this standard, they were quietly got rid of, so that the actual average consumption of the light per lamp was artificially raised above the normal gas average of the district. The cost of gas in the First District of New York is about 9s. 2d. per 1,000 cubic feet. Competition, therefore, with the elder illuminant, having regard to the the power of picking the good customers, and of unreserved access to the streets, was rendered distinctly favourable. Added to this was the fact of Mr. Edison's presence, and the supply of ample funds; still, the financial result is disappointing. The management of the station has been—at any rate during the period over which the returns extend—able, economical, and efficient. Not only is American genius more suited to the exploitation of new industrial developments than that of older countries, but there is a general disposition to help along a new scientific undertaking. The cost of the station is somewhat in excess of £200,000, and the annual expenditure is at the rate of nearly £16,000 a year—without including depreciation, sinking fund, or interest on capital. The excess of receipts over actual cash outlay amounts to about £6,000 a year, or 3 per cent. on the capital invested. In order to appreciate the precise nature of the result of this experiment, it is necessary to suppose that each lamp is replaced by a 5-foot gas burner, and that the amount of gas consumed to produce an equivalent of light be computed. The result of this calculation gives 6s. 11d. as the cost per 1,000 cubic feet of the gas thus consumed. If, however, a 16-candle lamp be held to compete with a 7-foot gas jet, then the equivalent is as nearly as may be 5s. per 1,000 cubic feet. To compete with gas at 3s., the cost of maintenance—*i.e.*, of production—must be reduced by two-thirds.

TERRESTRIAL MAGNETISM.—M. J. B. Baille contributes to *L'Electricien* the following note on measuring the horizontal component of terrestrial magnetism by the dead beat (*amortissement*) method:—The horizontal component T of terrestrial magnetism is generally determined in absolute value by the method of Gauss, which gives at the same time the magnetic moment M of the bar magnet. But the application of this method has several disadvantages. It is necessary to employ two magnets and make two observations independent of each other, separated by a sufficiently long interval of time, during which the terrestrial force may vary. I propose to apply to this investigation the old observation of Gambey and of Arago on the prompt dead beat of magnets oscillating above a thick copper plate. It is well known that a magnetised bar, oscillating inside a coil, is more or less dead-beat according as the coil constitutes an open or closed circuit. On measuring the dead beat in both cases, the moment h of the reaction which the induced currents exert on the movable magnet is obtained by difference. This element is connected with the magnetic moment of the oscillating bar M, and with the electric constants of the coil, a resistance expressed in W ohms, and G galvanic constant in centimetres, by the well-known formula $M^2 = W G^2/h$. If then h be measured, and if the value of the constants WG^2 be known at the moment of making the observation, M may be calculated. Now, as the directing couple T M has been already determined by means of the duration of an oscillation and knowledge of the moment of inertia, the number T may be obtained by a division, into absolute value, into units C.-G.-S, for instance, if all the other elements have been measured with the corresponding units. This method is very simple and very rapid; it requires the use of only a single magnet, which may be always the same, and it lasts scarcely a few minutes. Moreover, it appears, perhaps, still more precise than Gauss's method, since it gives the horizontal component at the precise moment of the observation. Besides, the dead beat of an oscillating motion is one of the physical elements which it is easiest to determine with accuracy, when suitable precautions are taken to secure good oscillations; and the observation of it may be made at the same time as that of the duration of the oscillations. There are, however, two difficulties which may greatly disturb the measurements, if care be not taken to allow for them. In the first place, the effect of the self-induction is to change the induced currents. It is therefore necessary to make a suitable correction at each observation; but it is simpler to eliminate this cause of error, which may be done by taking a coil having a small number of turns of wire, and especially by attaching to the magnet a piece having a strong moment of inertia, so that the duration of an oscillation be sufficiently long. Next, the variation of the declension has the effect of rendering the dead beat unsymmetrical, and presents itself like an irregularity of the oscillations. This source of error may be neglected if care be taken to make the observations quickly, and to take into consideration an even number of amplitudes. The declension may in that case be regarded as having varied regularly. The constants of the coil to be previously determined are the electrical resistance W, which will be increased by ordinary methods, and which will be reduced, by means of a suitable correction, to the temperature of the observation, and then the galvanometric constant G. This last element is sufficiently difficult to obtain by ordinary methods; but it might have been concluded from the first dead beat observations, if care was taken to put in the coil a bar the magnetic moment of which was determined beforehand by Gauss's method. I have applied the dead-beat method, as now described, with a coil, the electric elements of which were measured separately. I have determined the horizontal terrestrial component in my magnetic observation at Villeneuve-Saint-Georges. From numerous results which I have obtained, and which agree well with one another, I extract the following observations, in which the two methods were employed concurrently (C.-G.-S. units):—On 25th September: Magnet A, Gauss method, 0·1943; dead beat method, 0·1938; Magnet B, Gauss, 0·19413; dead beat, 0·19532. 26th September: Magnet M, Gauss, 0·19487; dead beat, 0·19512; Magnet N, Gauss, 0·1945; dead beat, 0·19464. As may be seen, the results are as concordant as possible, and the method I describe is worthy of all confidence.

THE STEAM ENGINE INDICATOR.—III.

BY AMICE.

Towards the conclusion of the article in our last impression we gave the reasons which made it necessary to employ, in an indicator for taking diagrams from modern engines, a spring of short range and a piston as light as possible, and light attached parts. These requirements were, as far as seemed necessary at the time, embodied in Richards's indicator, of which we now give an engraving (Fig. 7), showing the indicator as originally made. This gives but an external view, which is sufficient for our present purpose. It will be seen that the piston rod is attached by a short link to an arm forming part of a small parallel motion. This attachment is made at one-fourth of the length of the arm from its fulcrum on the indicator frame. The end of this arm has, therefore, a range of movement four times that of the indicator piston,

The Richards Indicator, 1868.

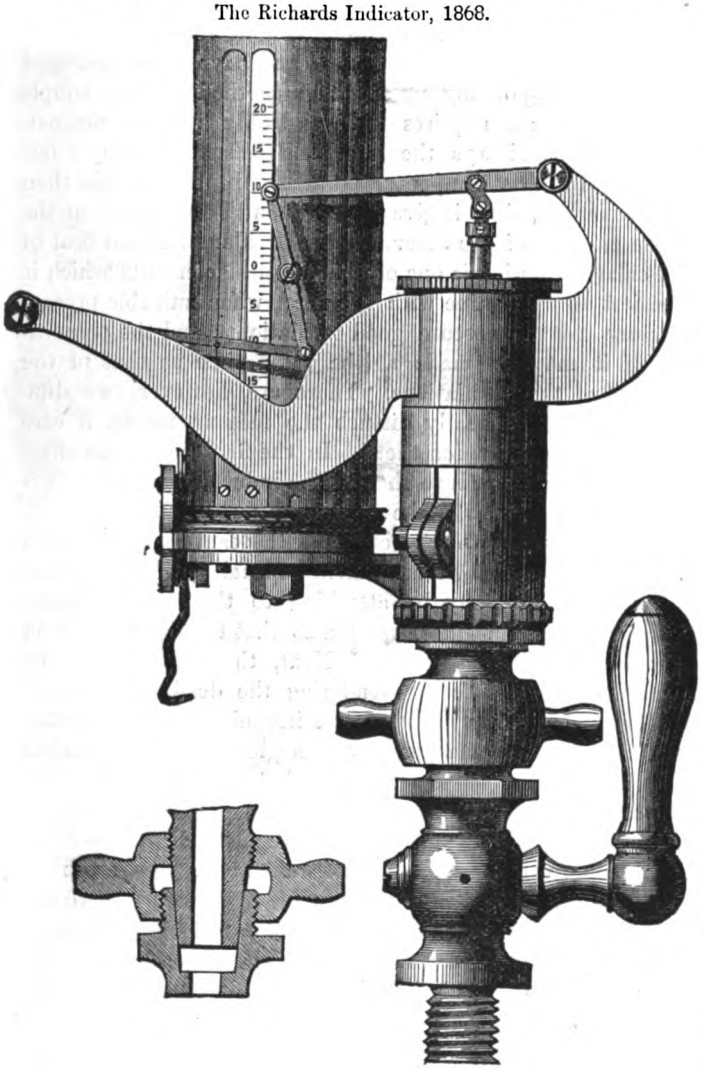

Fig. 8 Fig. 7.

and, consequently, the pencil which is carried at the centre of the middle member of the parallel motion has the same range. The indicator card, or paper on which the indication is taken, is placed upon the drum seen behind the pencil, and held by the light spring clip, one part of which is shown graduated. The strong curved arm carrying the parallel motion is free to turn upon the outer part of the indicator cylinder, and thus the pencil may be withdrawn from or put into contact with the drum on which the paper is wound. By means of the cord seen below the paper drum, and in the grooved sheave at the bottom of the drum the latter is attached to some part of the engine, so as to receive motion synchronous with the steam engine piston. The return motion of the drum is effected by a coiled spring within the drum. The string is thus always kept tight under the tension due to the spring in the drum. As the velocity of recoil of a steel spring is about 1,300 feet per second, no engine piston moves fast enough to cause the slack in the string which produced the jerky motion in the return stroke as effected by a weight in the Watt indicator. The small engraving (Fig. 8) is a section of the upper part of the cock which is screwed into the steam-engine cylinder or a pipe attached thereto, and of the lower part of the indicator cylinder with the fly-nut by which the indicator is attached to the cock. Two of these cocks may be employed, one fixed on either end of the engine cylinder. To take a diagram from either end of the cylinder it is, then, only necessary to remove the indicator from either fixed cock by unscrewing the fly-nut, the taper end of the indicator cylinder being steam-tight in the upper part of either cock. Instead of this it is common when a number of diagrams have to be taken to connect the two ends of the cylinder by a pipe with one three-way cock in the centre, to which the indicator points; it is then only necessary to turn the cock one way or the other to take a diagram from either end.

This indicator was a very great improvement on the best that had preceded it, and is at the present time very largely in use with but minor improvements. These improvements are, however, of considerable value, and as it is not necessary to show them separately, we may show them by reference to the recent form of Richards indicator shown in Fig. 8A and to a modification of the Richards indicator by Mr. Richardson, by means of which a continuous series of indications may be taken on a long strip of paper. This indicator is an improvement upon one made by MM. Guinotte and De Hennault, also introduced by Messrs. Elliott Brothers, and shown by Fig. 9, and Fig. 10 is illustrative on a small scale of a series of diagrams taken from an engine with Corliss's valve gear. One of the improvements consists in the use of the fly-nut below the paper drum by which the part carrying the little pulleys which guide the string can be without loss of time adjusted to any position which may be necessary to place them in a line with the string when attached to the moving part of a steam engine. A second improvement consists in the use of a device for instantaneously stopping or starting the paper drum without disconnecting the string by which the motion is communicated to the drum. With slow running engines the latter is not at all difficult, but with high speeds it is not only sometimes difficult to disconnect or connect the string to the indicator while the engine is running, but is sometimes dangerous. The device by which this is overcome is known as Darke's patent detent. It is simple, and consists of a ratchet segment on the bottom of the paper drum, and a small pawl controlled by a light spring attached to the outside of the cylinder. The pawl is seen in Fig. 9, upon a short pedestal between the drum and cylinder. As shown, it is out of gear, but if the string were pulled and the drum turned as in work, so as to bring the ratchet teeth round about three-fourths of a revolution from the position shown, the pawl would, by moving the little knob on the spring in front of the cylinder, go into gear, and the drum would be held by it against the resistance of the drum spring. The string would then hang slack during the return stroke of the reciprocating part of the engine by which the string is moved. These two engravings show the distinguishing features of the Richards indicator as far as external parts are concerned; but, as already observed, it was not only the use of the parallel motion which formed a feature, but the use of a short spring, with light internal piston. To these springs we shall refer further on. For the present, having the continuous indicator before us, we may briefly describe it. It is in form a Richards indicator, but is somewhat larger, more especially in the drum. In the interior of the latter is a receptacle for a roll of paper, the end of which is brought through a slot. It is then passed round the cylinder, and is inserted again into the interior, when it is caught by a slotted roller, which roller is worked in one direction during the motion of the paper drum. The backward and forward rotation of the drum gives intermittent motion to a train of small gearing, part of which is seen in the upper part of the drum. By means of the notched disc at the top of the drum, and the little spring catch lever which takes into the notches, diagrams may either be taken continuously, or if necessary single diagrams

Digitized by Google

may be taken in the same way as an ordinary Richards indicator, or by throwing the drum out of gear by the Darke's detent they may be taken occasionally. When the notched disc is set fast by the spring catch shown in one of the notches, the small train of gearing by which the roll of paper is actuated is in gear, but when the catch is not in the notch the whole of the drum and its contents work just as an ordinary Richards indicator, and single diagrams can be taken in the ordinary way. When the diagrams have all been taken, the length of paper can readily be pulled off the roller. The paper is supplied in rolls, and the trouble of coiling it on the cylinder is entirely avoided. About 150 diagrams can be taken on each roll of paper.

Modern practice has continually increased not only the speed of engines, but the pressure at which they work, and the necessity has arisen for an indicator which has moving parts for carrying the pencil even lighter than those in that of Richards. The reasons which made Richards' invention necessary have again made it necessary to improve the apparatus. Not only do the high speeds and pressures tend to break the parallel motion, but the several parts spring a little, and this with slight looseness in the joints, together with the inertia of the whole, conspire to increase the unsteadiness of the pressure line, giving to it a fluctuating waving form which is not a faithful representation of the real pressure in the cylinder. The total error, however, has probably been exaggerated, except with respect to what are now known as high speed engines, but a modification has become sufficiently imperative to induce Messrs. Elliot Brothers, of Charing-cross, who have been the sole makers of the Richards indicator, to bring out the form of indicator known as Darke's patent; and even the Richards indicators now made by them are fitted with Darke's pencil motion instead of the parallel motion, unless otherwise ordered. We will therefore, before entering upon the use of the steam engine indicator, describe this latest development of the instrument by these well-known makers; but inasmuch as an indicator, known as Kraft's, and having a pencil arm with a free end and other points of interest, appeared before Darke's, we must first describe and illustrate this.

The Richards Indicator, 1882.

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 29.)

m_1 Coils in Sequence with m_2 Coils in Parallel.

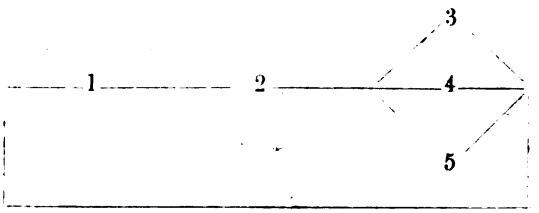
It may be inferred from the preceding that, if we join up equal coils in any manner to form a linear system of conductors the determinantal equation of the system will be merely $x^a y^b = 0$, a and b being integers. This will be evident from the section to follow on unequal coils, so at present we take it for granted, to avoid unnecessary repetition. The general case of a linear system, with equal coils, will be considerably lightened by first taking a simple case combining coils in sequence, and coils in parallel, say two coils in sequence with three in parallel, as in the figure (which I dare say the printers will be able to make up, as it consists wholly of straight lines and numerals. *See* page 48).

The numerals showing the position of the coils, and the lines their connections, given at a certain moment there to be distributions of magnetic force H_1, H_2, &c., in the five cores, and that there are no external impressed forces, the manner of subsidence is required, knowing that it is the resultant of the two manners corresponding to $x = 0$ and $y = 0$.

Let there be, in the first place, a distribution of magnetic force H_1 in the first core only, the rest being uncharged. Whatever current is set up in the 1st coil, we must, by continuity, have the same current in the 2nd, and by continuity

Digitized by Google

and symmetry one-third of this current in the 3rd, 4th, and 5th coils, all similarly directed, say from left to right. The proportions are 1, 1, $\frac{1}{3}$, $\frac{1}{3}$, $\frac{1}{3}$, and these must be the relative magnitudes of the magnetic forces at the boundaries of the five cores, after the subsidence has commenced. Also, at the first moment, we have to cancel the magnetic force in the 2nd, 3rd, 4th, and 5th cores. Thus we must have another set, z, -1, $-\frac{1}{3}$, $-\frac{1}{3}$, $-\frac{1}{3}$, where z, for the 1st coil, is yet unsettled. To find it, by the



(Figure referred to in previous column.)

principle that this set must set up no current in the coils, the common $-\frac{1}{3}$ in the 3rd, 4th, and 5th branches must be balanced by $+\frac{1}{3}$ in the branch formed by the 1st and 2nd taken together. This gives $z=\frac{4}{3}$, and $1+z=\frac{7}{3}$, the complete boundary force in the 1st core on the same scale. So, multiplying by $\frac{3}{7}H_1$ throughout, we find

$$h_1=\tfrac{4}{7}H_1,\quad h_2=-\tfrac{3}{7}H_1,\quad h_3=h_4=h_5=-\tfrac{1}{7}H_1,\quad .\quad (120)$$

as the five distributions which subside in the first manner, without current in coils. A similar set of distributions corresponds to H_2, since the second coil is in sequence with the first, giving

$$h_1=-\tfrac{3}{7}H_2,\quad h_2=\tfrac{4}{7}H_2,\quad h_3=h_4=h_5=-\tfrac{1}{7}H_2,\quad .\quad .\quad (121)$$

to subside in the first manner.

With H_3 the distributions are different. The current of strength 1 in the 3rd coil, due to E.M.F. in itself only, divides thus

$$\tfrac{1}{5},\quad \tfrac{1}{5},\quad 1,\quad -\tfrac{2}{5},\quad -\tfrac{2}{5},$$

in the five coils, and these are the proportions of the boundary magnetic forces. To cancel them at the first moment in all cores except the 3rd, we require the supplementary set

$$-\tfrac{1}{5},\quad -\tfrac{1}{5},\quad z,\quad \tfrac{2}{5},\quad \tfrac{2}{5};$$

where z must evidently be $\frac{2}{5}$. This gives us, multiplying by $\frac{5}{7}H_3$,

$$h_1=h_2=-\tfrac{1}{7}H_3,\quad h_3=h_4=h_5=\tfrac{2}{7}H_3,\quad .\quad .\quad .\quad (122)$$

to subside in the first manner. The corresponding distributions for H_4 and H_5 are got by writing first H_4 and then H_5 for H_3 in (122). Putting together (120), (121), (122), and the two equations similar to the last, we find h_1, h_2, ..., the complete distributions to subside in the first manner, to be

$$\left.\begin{aligned} h_1&=\tfrac{4}{7}H_1-\tfrac{3}{7}H_2\quad -\tfrac{1}{7}(H_3+H_4+H_5),\\ h_2&=-\tfrac{3}{7}H_1+\tfrac{4}{7}H_2-\tfrac{1}{7}(.\ .\ .\ .\ .),\\ h_3=h_4=h_5&=-\tfrac{1}{7}(H_1+H_2)+\tfrac{2}{7}(.\ .\ .\ .\ .),\end{aligned}\right\}\quad .\quad .\quad (123)$$

The complementary distributions H_1-h_1, H_2-h_2, &c., are to subside in the second manner, as if the coils were short circuited.

In all the preceding relating to coils in sequence and in parallel, we have, for facility of description, referred to the H's as the initial distributions in the *cores*. But should the coils be not of very small depth, we must, along with the core distribution H, consider the coil distribution of magnetic force; and, again, if there be external self-induction associated with the coil, there is a certain unknown distribution, though known amount, of magnetic induction, depending on the strength of the coil current. These supplements to the H's have to be treated in the same manner as the H's, and may be imagined to be included in them.

Any Combination of Equal Coils, with Cores.

It may have been observed by the attentive reader (I hope I have at least one), especially in a study of the contents of the last section relating to five coils, that there is a general principle underlying the method of finding the two sets of distributions, a knowledge of which is essential in finding how the subsidence takes place. The principle, like most principles, shows itself more prominently by putting on one side all the insignificant details of special solutions (although the study of special solutions is, if not indispensable, at least very desirable), and viewing the matter more generally. First, to define what is meant by "any combination . . ." in the title of this section. It is any combination as hereinafter set forth and described. The unit, which is the element of the combination, is a coil with a core, joined in sequence with an external conductor. Any number of such units, all alike as regards main coils, cores, and external conductors, may be connected in sequence to form a branch; and, finally, any number of branches, containing different numbers of units, may be joined together to form a network, a linear system of conductors, so far as the wire of the coils and external conductors is concerned.

Given at any moment the state of magnetic force (subject to the previous restrictions as to direction and symmetry) in all the cores, with, if necessary, the strength of current in each coil at the same time, what happens when the system is left to itself without impressed E.M.F., that is, left under the influence of the E.M.F.'s of induction only? We may, for instance, imagine the separate units, previously separately charged, to be instantaneously connected together to form the aforesaid combination.

The complete solution may be expressed in terms of the already-obtained two solutions. The one is that which expresses what happens when a unit, as above specified, previously charged, is left to itself with the coil circuit interrupted; the other expresses what happens under the same circumstances except that the coil circuit is closed. In the first case we have induced currents in the core only; in the second case in the coil also, and with a different and slower manner of subsidence of the core's magnetisation, if there be any, or in general, of the magnetic induction. The determinantal equation of the combination is of the form $x^a y^b=0$, and we have $x=0$ for the first manner and $y=0$ for the second manner of subsidence. We only require to decompose the initially given states into two sets, such that in one of them we shall have $x=0$, and subsidence as if all the wires were disconnected, and in the other $y=0$, or subsidence as if every unit formed an independent closed circuit.

This may be done generally, as done in the last section with a simple combination, by making use of the following property connecting steady impressed forces and currents in a linear system of conductors. Let the resistances of the different branches be R_1, R_2, ...; the impressed forces acting in them $E_1, E_2, \ldots$, and let the currents be $C_1, C_2, \ldots$. These currents are what result from the simultaneous action of all the impressed forces. They may be found by the application of Ohm's law to every conductor; either symmetrically, or, when the system is not very complex, by the easier ways that present themselves.

Now remove the impressed forces $E_1, E_2 \ldots$, and substitute others $F_1, F_2, \ldots$, of such strengths that

$$F_1=E_1-R_1C_1,\qquad F_2=E_2-R_2C_2,\ \&c.$$

There will now be no current in any of the conductors.

This may be very easily seen. For, if in the original distribution of current, the rises of potential in the directions of the currents C_1, &c., in the conductors of resistances R_1, &c., be ΔP_1, ΔP_2, &c., the complete E.M.F.'s in the branches are $E_1-\Delta P_1$, $E_2-\Delta P_2$, &c. Hence, by Ohm's law,

$$E_1-\Delta P_1=R_1C_1,\qquad E_2-\Delta P_2=R_2C_2,\ \&c.$$

Thus, our defined second set of impressed forces to take the place of E_1, &c., are given by

$$F_1=\Delta P_1,\qquad F_2=\Delta P_2,\ \&c.$$

and consequently, by the elementary potential property, there is no resultant impressed force in any of the closed circuits that can be made up in the linear system, and therefore no current in any of the branches.

[In three dimensional steady flow, ρ being the specific resistance, E the impressed force per unit length, γ the current

Digitized by Google

density, and P the potential, we have

$$E - \nabla P = \rho\gamma$$

in the first distribution; and the second distribution of impressed force is $F = \nabla P$, producing no current.]

Thus, with an impressed force in one conductor only to start with, there is a definite distribution of impressed force in the whole system that gives no current; so, if there are m branches, there are m different systems of balancing impressed forces, and the perfectly general system is to be got by taking these m systems simultaneously, in any separate proportions of strength.

We have now only to apply this property to our combination. Let an impressed force of unit strength act steadily in one of the coils, say the first, and find the distribution of current set up. Let it be e_1/r, e_2/r, e_3/r, &c., where r is the common resistance of every unit in the combination. Thus e_1, e_2, e_3, ... are a set of proper fractions, and the set of impressed forces of strengths $1 - e_1$, $-e_2$, $-e_3$, &c., in the first, second, &c., coils would, by the preceding, set up no current in the coils. Let H_1 be the initial magnetic force in the first core, a function of the distance from the axis, and let the other cores be uncharged. The distributions e_1H_1, e_2H_1, e_3H_1, &c., if they existed alone would subside in the second manner, as if every unit in the combination formed a separate closed circuit. The supplementary distributions $(1 - e_1)H_1$, $-e_2H_1$, $-e_3H_1$, &c., if they existed alone, would subside in the first manner, without current in the coils. Superimpose these two distributions, and we have the actual initial distribution, and at any subsequent moment the state of the system will be the resultant of what these distributions would have then become. Similarly we may treat the initial magnetic forces in the other cores. If the second coil be in sequence with the first the same set of ratios e_1, e_2, e_3, ..., is to be used. But in passing to another branch in the combinations, we must, in general, find another set of ratios. Having gone over the whole combination in this way, it is a question of simple addition or subtraction to obtain the final resultant solutions.

(TO BE CONTINUED.)

ELECTRIC LIGHT ON THE BRIGHTON LINE.

On Tuesday evening last, the Board of Trade inspectors made themselves acquainted with the working of the system of electric lighting applied by the London, Brighton, and South Coast Railway Company to a local train, which works their suburban traffic between Victoria, the Crystal Palace, and London Bridge. This, the first train which has been fitted with a self-supplying source of current for electric lighting, consists of eleven carriages, which are lighted by thirty-two 16-candle incandescent lamps. The train began running on 19th December, 1883, and has, with slight exceptions, been working ever since, having made 2,352 trips and run about 27,322 miles.

The system of lighting is the joint invention of Mr. Stroudley, the locomotive superintendent, and Mr. Houghton, the telegraph engineer, who began their experiments in this direction two and half years ago. It was first tried by M. Philippart, then by Messrs. Ayrton and Perry, and then handed over to the Railway Electrical Contractors (Limited), by whose manager, Mr. T. M. Collet, it has been brought into practical operation. In the installation on the Brighton line a No. 5 shunt-wound Brush dynamo of 45 volts (placed in the guard's van), giving about 38 amperes, is driven constantly by a link belt off a pulley on an intermediate shaft, which receives its motion by similar means from one of the axles. When the speed exceeds 20 miles an hour, an ingenious controlling apparatus, somewhat resembling the ordinary speed indicator, makes contact, and thus brings two pairs of brushes on to the commutator. This controlling apparatus consists of a small hollow cylinder filled with mercury, placed in a horizontal position, and having two vertical tubes in communication, one with each end. In the cylinder works an Archimedean screw, driven by a strap from the dynamo spindle. As the speed of the train, of the dynamo, and consequently of the screw increases, the mercury rises in one or other tube, according to the direction of the train; and when it reaches the metallic contact, which may be set by a screw to correspond with any speed, one or other set of brushes is brought on to the commutator. By this arrangement the dynamo is only connected with the accumulators when its E.M.F. is higher than that in the batteries.

The electrical energy is stored up in twenty-two Faure-Sellon-Volckmar accumulators, weighing about 1cwt. each, while the dynamo weighs 8cwt., thus making altogether only an additional weight of one ton and a half. When, however, the lamp circuit is switched on, the current goes direct to the lamps, by the law that electricity chooses the path of least resistance, only the excess of current, if any, then going into the accumulators. Thus the dynamo generates, during the day, a reserve of energy for use at night; and therefore it is not necessary to employ a dynamo of the full power required for maintaining the lamps. Besides being on during the night, the lamps are turned on by the guard, by means of a switch in his van, while passing through tunnels; and here be it remarked that no electrician is required to accompany the train, while the additional power absorbed by the dynamo is amply supplied by a few hundredweight of coal extra on a 50 mile journey. The wires are coupled up between the carriages by the simple connection of a pin entering a socket, which permits of this connection being broken automatically on uncoupling the carriages. It was feared that the jarring of the train would exert an injurious influence on the storage batteries; but such has not been the case; on the contrary, it has been found beneficial by preventing the formation of any deposit on the plates. The dynamo and batteries are so calculated that, even if the train ran at the rate of 60 miles an hour, too much current would not be generated for the batteries; but, in such a case, a controlling apparatus would prevent the storage battery from working back upon the dynamo.

The application of this system of lighting to a local, stopping train, places it at great disadvantage, and fully tests its value. A similar plant is also fitted to two expresses between London and Brighton. The local train started soon after 7 p.m. on Tuesday, and ran to the Crystal Palace and back, taking up passengers at every station in the ordinary way. We were unfortunate in getting into a compartment where the light, though steady when stopping, was by no means uniform while running; but as, on comparing notes with other visitors, we found this was by no means the case generally, we are disposed to attribute the variation to insufficient contact in the lamp-holder. Besides the three inspectors of the Board of Trade—Colonel Rich, Colonel Yolland, and Major Armstrong, R.E.—there were present:—Mr. John Pender, M.P., chairman of the Eastern Telegraph Company; the Hon. Thos. Freemantle and Mr. Lopes, directors of the Brighton Company; Mr. J. P. Knight, the general manager; and Mr. Richardson, superintendent of the line; Sir Daniel Cooper, Bart.; Sir Henry Tyler, M.P.; Mr. Latimer Clark; Mr. Verrinder, superintendent of the South-Western Railway; Mr. Spagnoletti, telegraph engineer on the Great Western Railway; and other gentlemen scientifically interested in the progress of electric lighting.

FATAL ACCIDENT FROM ELECTRIC CURRENT.

On Tuesday last a fatal accident happened to a man named Moore, at the Eston Steel Works of Messrs. Bolckow, Vaughan, and Co. (Limited), near Middlesbrough. It is reported that, while an examination of the engine was being made, the electric light began to flicker. An engine driver named Moore picked up a piece of stick, and put the end of it against the lamp, with the intention of adjusting the carbons. For an instant the light went out; and Moore, thinking perhaps that the electric current had been switched off, caught hold of the apparatus in the lamp. He had hardly touched the lamp when the current returned in full force, and sent such a severe shock through his body that he instantly fell back dead.

DR. EDWARD DAVY.

It was with some natural feeling of pride we were able to announce in our last issue that the distinction of Honorary Member of the Society of Telegraph Engineers and of Electricians had been conferred upon Mr. Edward Davy, and that by the appreciative courtesy of the Eastern and Eastern Extension Telegraph Companies the fact had been communicated to him by telegraph and his acknowledgments duly received. To Mr. Fahie's industry we owe the discovery which Mr. Davy's modesty had allowed to be well nigh forgotten; and to Mr. Fahie's chivalrous advocacy, chiefly through the columns of this journal, Mr. Davy owes the tardy but well deserved recognition of his merits as an inventor of electric telegraphy. It must have been peculiarly gratifying to Mr. Davy that the news of his preferment, so to speak, to the rank of peer among practical electricians should reach him by the very medium which he had predicted forty-six years ago would one day be able to annihilate distance both by land and sea—a prediction which he himself had a large, though till now unacknowledged, share in fulfilling. In the year 1838 Mr. Davy was so confident of the future of the experimental telegraph on which he was then engaged that he could not avoid "looking at the system of electrical communication between distant places as a system which will one of these days become an especial element in social intercourse. As railways are already doing, it will tend still further to bring remote places in effect nearer together. If the one may be said to diminish distance the other may be said to annihilate it altogether, being instantaneous." He also foreshadowed a system of insulated conductor or "cable" for submarine communication; and even expressed his conviction that the Government would, or rather ought to, take this newly discovered means of instantaneous communication into its own hands "as a branch of the Post Office." In the letter which contains this remarkable piece of advice Mr. Davy adds, with perhaps some inward misgivings, that he can "scarcely imagine that there would be such absurd illiberality as to appropriate it (the invention) without compensation." Imagination almost fails us when we try to picture the money compensation that might have been earned and saved by the "Government" had it acted on Mr. Davy's suggestion.

It is not as a prophet, however, that the obscure chemist of 1838 is entitled to honour in his own country. Inventors are not unusually prophetic; they see what they wish to see, and what lookers-on cannot fathom, simply because their eyes are not sharpened by self-interest or brightened by the expectation of fame. It is a commonplace joke to ridicule the blindness of great men's contemporaries; but greatness is a relative term, and a title to exceptional renown is earned by greatness exceeding that of one's neighbours. Mr. Davy, as was quite natural in the circumstances, saw a vast deal further into the future of electric telegraph than other people; but to say that they were stupid or obstinate in not seeing exactly what he saw would be to deprive him of the special distinction which is his due. That distinction is a small matter, however, compared with the practical work he actually achieved. For a correct estimate of the world's indebtedness in this respect to Dr. Davy our readers may refer to last year's *Electrician* (Vol. XI., Nos. 8, 9, 10, and 11), where the result of Mr. Fahie's investigations into Davy's connection with the earliest history of practical telegraphy is fully set forth. The account would be a remarkable one in any case; but coming as it did so many years after the events to which they related the disclosures were simply astounding. They showed beyond all possible cavil that we had credited the invention of the telegraph to the wrong persons, or at all events had not credited it to one person whose claim was as strong or stronger than theirs. Some years prior to the patent of Cooke and Wheatstone, Davy had experimented successfully with the system devised by him, and had matured it before they obtained security at the Patent Office for theirs. His system was wonderfully complete, more so than the one which thrust it aside, and in several respects it forestalled inventions and appliances of a still later period. The curious may inquire into the subject as a phase in the ethics of patents. All we are concerned with, however, is to state the facts, and to congratulate the world in being fortunate enough to do an act of justice, and Mr. Davy in having justice done to him in his own lifetime.

Mr. Davy's honours were snatched from him at a moment when their fitting reward would have been most opportune. In the interests of that social and commercial intercourse

Digitized by Google

which the telegraph was so greatly to advance it was perhaps fortunate that its promotion fell into hands more energetic, more self-asserting, and more business-like than Mr. Davy could pretend to. That he left England without any public assertion of his claims, that he has remained in Australia, become one of the founders of the Royal Society of Victoria, and has never lost his interest in scientific research during all these years—and yet has left the fact of his earliest and greatest achievement to the accidental finding of a generous stranger in his native land—is an example of modesty as marvellous as it is admirable. To such a man the prompt recognition of his genius by an English learned society specially representative of electrical and telegraphic research will probably be more highly prized in his old age than would have been the pecuniary reward which he pursued with such indifference and abandoned with such unconcern in the prime of life. We sincerely hope it may be so.

CORRESPONDENCE.

ELECTRIC LIGHTING AT A PROFIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was rather surprised to find that all the technical journals of last week's issues had failed to notice an article in the *Pall Mall Gazette* of November 20th, entitled "Electric Lighting at a Profit."

From Mr. Hammond's presence in the deputation which waited on the President of the Board of Trade, I must assume that he agreed with its object, viz., to prove that the Electric Lighting Act is a failure, and that although he may find capitalists willing to put money into electric light enterprises if unfettered by the Act, they will not do so when the Act comes into force.

I notice also Mr. Offor's presence in that deputation, and assume that he finds the same; and I think I may congratulate him on having the *only* instance of an installation worked under the Act. It is general knowledge that the B. T. K. system is only Sir William Thomson's system as promulgated at the Royal Society in 1881, modified in its details and application to meet the requirements of the Electric Lighting Act, and no higher recommendation could be desired. I understand that the directors and management of the South Eastern Brush Company believe that that system will be a commercial success. Undoubtedly the system is right if they have the necessary apparatus to carry it into effect; but upon the question of necessary apparatus I cannot speak, as I do not know.

I believe I am further correct in saying that this system has met with the approval of the Board of Trade.

Presuming such to be the case, through Mr. Offor being one of the deputation, and that he cannot find capitalists willing to help him with other installations, while the Colchester installation has been carried out with company's money, raised before the Electric Lighting Act was passed, we have another argument to bring forward for alterations in Section 27 of the Act, and also in the Provisional Orders, as to questions of the compulsory laying of mains, and the use to which the electric current supplied is to be applied.

The portion of the article, however, to which I wish to draw attention is the system by which Mr. Hammond proposes to make electric lighting profitable—viz., the use of high tensioned currents flowing direct into consumers' premises. Now, "Save me from my friends" is an old saying, and I would certainly say, in the interests of electric light, save me from Mr. Hammond; for he must use currents of a potential that will never be tolerated by the Board of Trade, and which no electrician would dare to recommend for general adoption. No wonder that no private house has yet been lit at Brighton, seeing that a number, say eight or ten lamps, must either be all alight at the same time or not at all. I am aware that in the multiple series system a resistance can be inserted in place of a lamp being turned out; but it would not be economical, and practically the consumer must pay for the current passing through his multiple series, whether he burn the whole or not.

Mr. Hammond has no doubt induced the authorities at Hastings and Eastbourne to give him permission to lay his wires down for more than 21 years, and the details of his agreement with them would be very interesting, particularly to those who have loose capital to invest.

The principle of the Hammond-Wright system is old, but its application and the details of the working out reflect great credit upon the above-named gentleman. It is a system, however, which never could become one for general adoption until a discovery is made whereby a difference of potential of 600 volts and upwards between the line wire and the earth shall not cause either danger of fire or loss or damage to life or limb.

Knowing Mr. Hammond as I do, I feel certain that he will be pained when the impression which this article produces upon the public is made known to him. Would it not be well, while there is yet time, if he would devote his attention to, not necessarily the B.T.K. system, but something of a similar character? for the idea of a direct-running system, whatever potential may be used, has already been practically demonstrated as a failure from a commercial point of view, when continuous supply is required.

That portion of the public which is longing for the electric light has been looking towards Mr. Hammond, but when they see him going in for a scheme which is fraught with danger to life and limb, they rather feel "save us from our friends" and leave us to our enemies, or rather over-careful friends the Board of Trade.—Yours, &c., M.S.T.E.

THE BOARD OF TRADE AND ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Chamberlain's reply to the deputation of the 20th instant encourages discussion upon the terms of the option of purchase under sec. 27 of the Electric Lighting Act, 1882. That there *is* to be an option seems a foregone conclusion. To take the discussion out of the region of pure speculation, I shall take a parallel case in actual experience.

Thirty years ago the financial practicability of railway enterprise in India was purely hypothetical. Experimentally and tentatively some progress had been made. So early as 1849 the East Indian Railway Company had been incorporated by Act of the Imperial Parliament, and an experimental line was soon afterwards made by aid of a subvention from the Government, then that of the East Indian Company. The public were not easily to be convinced that railway works could be maintained under the climatic and physical conditions of the country; and, what is still more to the point, the problem still awaited solution how far the natives would make use of the accommodation to be provided. The Indian Government were desirous of attracting private capital to the enterprise, but for this it was necessary not only to confer a monopoly of powers, but to give a substantial pecuniary guarantee. In consenting to this sacrifice the Government were far-seeing enough to reserve to themselves an option of purchase, but the terms were carefully considered so as to be fair and not repellent to investors.

The final contract of the Indian Government with the East Indian Railway Company was made in 1854. The Govenment guaranteed a minimum dividend of £5 per cent.; surplus profits over that amount in any year were to be shared, one-half to go towards recouping the Government for their outlay on the guarantee, and the other half to increase the dividend. And there was to be an option of purchase by the Government, to be exercised by notice to be given within six months after the expiration of twenty-five years, *or* within six months after the expiration of fifty years, the purchase money to be

"A sum equal to the full amount of the value of all the shares and "capital stock in the company calculated *according to the mean market* "*value in London of such shares or stock during the three years imme-* "*diately preceding* the expiration of the said period of twenty-five years "or the said period of fifty years, as the case might be."

Digitized by Google

The terms of the contract so settled in 1854 were the basis of the great undertaking of the East Indian Railway Company, and, it may be said, of the railway system in India, for identical terms were embodied in the Government contracts with all the railway companies in the earlier undertakings in India.

To return to the East Indian Railway. The capital was subscribed on the strength of the contract of 1854, and the undertaking carried out. After some years the profits were found frequently to exceed the guaranteed amount, so that, after dividing the surplus with the Government according to the arrangement, a dividend of ½, 1, or even 2 per cent. over the guaranteed 5 per cent. was paid to the shareholders. The stock improved steadily, and as the time came near for exercising the option stood at about 25 per cent. premium. At this time a momentary panic was caused by a letter to *The Times* calling attention to the existence of the option. But when those concerned had time to look into the matter the terms of the clause were found to have been adjusted with such fairness and foresight that prices quickly resumed the usual quotations. Indeed, when the Government (now the Secretary of State, under the powers of the Act of 1858) finally decided to exercise the option, the only effect on the market was a slight rise, owing to certain fresh advantages conceded by the Government to holders, in order to secure the success of the large financial operation required for meeting the purchase money. The new arrangement (which is confirmed by an Act of the Imperial Parliament, 43 and 44 Vict., cap. 206) took effect from the 1st of January, 1880; and the Government acquired at the price of 25 per cent. premium — perhaps 50 per cent., including the amount expended under the guarantee—an undertaking of proved and increasing value, with the accumulated benefit of experience and successful management, in every respect a remunerative purchase. Indeed, so important was the success attributed to the private management that, under the new arrangement, the company retain a certain interest in the success of the undertaking, which continues to be carried on by the directors of the company on behalf of the Government.

A similar option has been lately exercised in the case of the Eastern Bengal Railway, by notice given in 1883, and under an arrangement confirmed by an Act of the Imperial Parliament in 1884. In some other cases the Government have not found it expedient to exercise the option; and perhaps there are cases, but these are exceptional, where it is never likely to be exercised. Even where the railway has been financially a comparative failure the public advantage has been doubtless a fair compensation for the loss on the Government guarantee. Such cases only illustrate the fairness of the terms of option under which the Government have acquired the undertakings which have proved successful.

In the case of electric lighting there is no question of guarantee. All that is asked is that undertakers for lighting on a large scale shall have the necessary powers, and (consequently) what may be called a *quasi* monopoly. In the case of the Indian railways, the option was part of the consideration for the pecuniary guarantee. The analogy does not indeed justify *any* condition for an option in the case of electric lighting. But, assuming that the principle of clause 27 is unalterable, and the option of purchase a *sine qui non*, the history of Indian railways, extending over the whole period up to and for some years beyond the actual exercise of the option, is a precedent showing the terms on which such an option can be made consistent, not only with the encouragement of private enterprise, but also (what is a point of some importance) with steadiness in the market value of the property affected.

That the Indian Government in new railway undertakings can and does impose harder terms is only an illustration of the difference between a new and untried enterprise and an undertaking on which the profits can be estimated by matured experience. This difference at once disposes of the supposed analogy between electric lighting and gas and water supply. There is the further difference in the case of water companies, that their concessions involve not only a monopoly, strictly so called, but the extensive appropriation of natural resources. False and misapplied analogies, indeed, pervade the whole existing legislation upon electric lighting.—Yours, &c.,

13, Old-square, Lincoln's Inn, R. CAMPBELL.

THE WATT AND HORSE-POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: He would be a very captious man indeed who should say that Professor Adams did not know what a "watt" was, and it was just because such an authority and such an accurate writer made a slip that I used it with such effect to point a moral.

The errors that he uses for his *tu quoque* argument are so evidently printer's or reporter's errors that I regret his having referred to them; for, although I cannot accept the responsibility of them, I should be sorry to call into question the generally wonderful accuracy of your scientific reports. If in the paragraph to which he refers he will substitute "watts per candle" for "watts per minute," he will see what I said. My absence in America prevented my revising the proof, which you would doubtless otherwise have had the courtesy to send me, and so I have had no opportunity to correct the errors which have crept in, and which I now see for the first time.—Yours, &c., W. H. PREECE.

General Post Office, St. Martin's-le-Grand,
24th November, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When Edwin calls me his angel, I can forgive him for temporarily forgetting that I am of one dimension in *mass*; and when Mr. Herbert Spencer calls everything *force*, we think that a man who has mastered every other science must be pardoned if his mechanics are not up to date; but when one who stands in the very front rank of physical science tells us that "*units of work per second are still units of work*," and that "*revolutions per minute are still revolutions*," I cannot help protesting against the total suppression of Father Time. It seems to me that, accepting the great professor's statement, I am compelled to believe that *units of length per second are units of length* or *velocity* is *distance*. Also *units of momentum per second* must be *units of momentum*, and *units of work per foot* must be *units of work*, although, when I attended lectures and mechanics at Girton, I was led to believe that each of these latter quantities were equivalent to *force*, so that *work* (or energy), *momentum*, and *force* are all the same, and Spencerian philosophy is, after all, triumphant. Having arrived at this result, would it not be better if our leaders would recognise that every one is liable in speaking and letter writing to err in the method of dimensions, and devote their energy to useful work?—Yours, &c., ANGELINA.

SELF-REGULATING MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last week's issue there is a passage on page 26, where the writer falls into an error, previously often corrected, as to the strict chronology relating to the invention of self-regulating machines.

The passage in question runs:—"The invention of compound winding has been claimed for others, but it remains a fact that *the first dynamo machines made practically self-regulating by the compound principle were those made and set to work by Messrs. Crompton for Mr. Coope at Berechurch Hall, near Colchester, in the spring of 1882.*"

The italics are mine that I may better draw attention to the perfect fallacy of the statement.

The first dynamo applied *practically to work* on the compound wound principle was by Dr. Paget Higgs at Greenpoint, Long Island, in 1881. It was a Wood's dynamo, made by the Fuller Company, and by the instructions of Dr. Higgs. The series coils on one side of the machine were replaced by fine wire shunt coils. This machine was subsequently removed to the corner of Chestnut-street and Seventh-street, Philadelphia, by Mr.

Digitized by Google

Russell A. Ballero, the well-known financial agent of Boston, and was there exhibited publicly, as well as before Governor Harbranft and the Hon. Mr. Moore, of that city. This machine was driven by a Colt's 6 horse-power disc engine, running at 900 revolutions, steam being got from a 10 horse-power Buxted boiler. Maxim's incandescent lamps were used. Moreover, the machine had been previously shown to Professor Trowbridge, of Harvard College, and the compound principle of winding explained to that scientist by Dr. Higgs, at the Fifth Avenue Hotel, New York.

Four Gramme machines were compound wound under Dr. Higgs's instructions as early as April, 1881, at New York, and are still at work.

In November, 1881, this gentleman shipped to me in Liverpool to my order two compound machines wholly made by him, and one of which is still in my possession in good working order.

In fact, as early as May, 1880, Dr. Higgs was constructing self-regulating machines of an experimental character in Boston, and his first application for letters patent for such is shown by the Commissioners' receipt, now before me, dated 22nd April, 1880. His patents for them, subsequently applied for and granted, bear the date of *April and May, 1881.*

I repeat that self-regulating compound wound machines were in this country and on view in November, 1881, within my own personal knowledge, and I may add, moreover, that as early as December, 1881, a compound machine wound to give a constant current was built under Dr. Higgs's instructions, and employed in America for arc lighting, an application that has never to my knowledge been attempted by any one else. Just a word more. It ought to be remembered, moreover, to the credit of Dr. Higgs that he is not a manufacturer like Mr. Crompton, to whom the writer of the erroneous statement in question is desirous of presenting the patent for self-regulating machines.

Such, however, is the spirit of opposition nowadays, that the toil of an inventor does not by any means end with his invention; it is only beginning with his Sisyphian labour of defending it.—Yours, &c., W. MACGREGOR.

26, Marmaduke-street, Liverpool.

[The passage referred to was carefully worded, and conveys, we think, the idea it was intended to convey. Dr. Paget Higgs's work in this direction has been fully discussed in our columns before, and no one wishes to detract any honour that is his due. It must be remembered that Mr. Edison claims the compound in 1879, a year earlier than is mentioned by Mr. Macgregor. *Vide* Vol. I. *Schellen*, published by Van Nostrand, pp. 490—491.—ED. *E.*]

A GENERAL INDEX.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The suggestion of one of your correspondents in last week's issue as to the preparation of a complete index for all the published volumes of *The Electrician* is a most excellent one. With this at hand and the volumes in question, one would then be able to give oneself a complete course of instruction in any of the branches of electrical science, which have grown from babes to striplings of late years. May I ask whether you are likely to find time amongst your various labours to arrange for the suggestion being given practical effect?—Yours, &c., A. D.

DEMAGNETISING WATCHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There are probably a good many of your readers who, like myself, have disabled watches owing to their having become magnetised. If any of your correspondents can give their experience of a simple way for demagnetising such watches, I am sure it will be of much service to many of those engaged in electrical work.—Yours, &c.,

Nov. 26, 1884. HAIRSPRING.

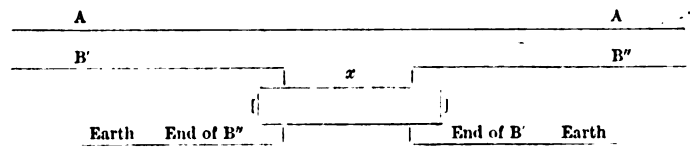
[Several letters on this subject appeared in our last volume, and to these our correspondent might well be referred.—ED. *E.*]

INDUCTION IN TELEPHONE CIRCUITS.

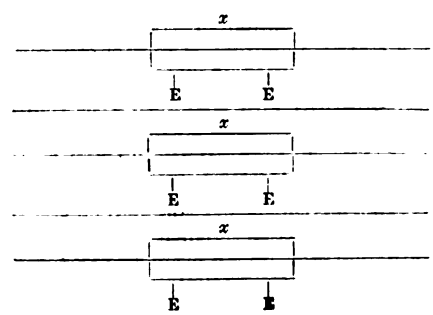
BY F. W. NEALE, STOKE-ON-TRENT.

No one but those who have experienced it can appreciate the worry and trouble telephonic induction has caused to telegraph engineers having charge of telephone circuits. I have the maintenance of two telephone circuits of five miles length each, with four instruments in circuit. The wires are on the same poles throughout, and as they are used by rival traders in the same line of business, the annoyance was intensified. Every means was tried to stop the induction without success, until I devised and carried out the following arrangement. It has stopped the induction, and the two circuits now work quite independently and without divulging each other's trade secrets.

A A and B′ B″ represent two parallel wires of telephone circuits. Under ordinary circumstances every word uttered on A A can be heard on B′ B″, and likewise the other way about. To stop this, cut one of the wires at half the distance, X, and insert an induction coil of two wires wound parallel to each other on the bobbin, as shown below. The length of wires in the induction coil must be regulated to the length of wire on the circuit on which it is to work.

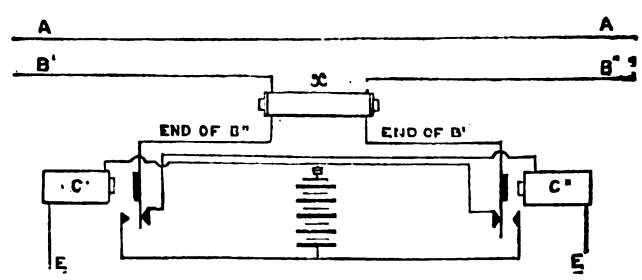


Any currents passing along B″ will pass to E at X, but will induce opposite currents in B″, and *vice versâ*. At the same time, the inductive action on A A in one half the line B′ will kill the inductive action on A A in the other half B″. This simple device can be applied to telephone circuits in different ways. It may sometimes be advisable to divide a circuit into three, and put in two induction coils. It can probably be arranged better where wires are put one over the other vertically thus, with the coils inserted alternately.



A magneto bell will ring well through the coil to the other end, with the current induced at X from either end, and will also ring well through two induction coils put in one circuit.

Where bells are rung with battery currents, I have worked them under the following arrangement:—

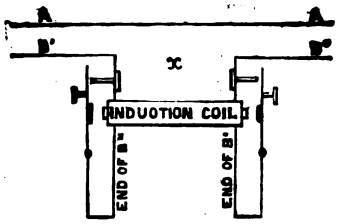


It is the induction coil inserted at half distance on B′B″ with an addition of two relays C′ and C″. A ringing current sent from either B′ or B″ pulls up the armature of C′ or C″, and puts a relay of battery power on to the other half the circuit, which rings the bell.

Mr. Brown, of the Walsall Electrical Company, to whom I communicated the above arrangement, in order that he

Digitized by Google

might also give it a trial, suggests the following simpler arrangement for circuits ringing with batteries, which has the advantage of dispensing with the relay of battery power.



It will be seen that a ringing current passing through the coil from either end pulls up the two armatures, thereby cutting off the earth and putting the circuit through at X so long as the ringing current is held on.

I may say that I have made no special secret of this arrangement, and after I had satisfied myself with nearly two years' trial of the second arrangement, I communicated the result to several of my friends, all of whom bear testimony to its efficiency. Any one troubled with induction is therefore at liberty to try it, as there is no intention of patenting it. It also has the advantage of improving the articulation in the telephone.

THE THEORY OF ALTERNATING CURRENTS.*

BY J. HOPKINSON, F.R.S.

(CONCLUDED FROM PAGE 36.)

V†. In all that precedes it is assumed, not only that γ is constant, but that the copper conductor of the armature is the only conductor moving in the field. If there be iron cores in the armature, we shall approximate to the effect by regarding such cores as a second conducting circuit. Slightly changing the notation, let L be coefficient of self-induction of the copper circuit, N coefficient of self-induction of the iron circuit and R^1 its resistance, I^1 the magnetic induction of the field magnets upon the iron circuit, and M the coefficient of mutual induction of the two circuits, y the current in the iron. The equations of motion are obtained from the expression for the energy, viz.,

$$\tfrac{1}{2}\{L x^2 + 2 M x y + N y^2 - 2 I x - 2 I' y\}$$

and are

$$L x' + M y' + R x = \frac{dI}{dt} = \frac{2\pi A}{T} \cos. \frac{2\pi t}{T}$$

$$M x' + N y' + R' y = \frac{dI'}{dt} = \frac{2\pi B}{T} \cos. \frac{2\pi t}{T}$$

for in general the iron cores and the copper conductor are symmetrically arranged. Assume

$$x = a \sin. \frac{2\pi t}{T} + b \cos. \frac{2\pi t}{T}$$

$$y = a' \sin. \frac{2\pi t}{T} + b' \cos. \frac{2\pi t}{T}$$

and substitute in the equations of motion, we have the following four equations to determine the constants, $a\ b\ a'\ b'$

$$a \frac{2\pi L}{T} + a' \frac{2\pi M}{T} + R b = \frac{2\pi A}{T},$$

or

$$a L + a' M + b \frac{T R}{2\pi} = A$$

and

$$b L + b' M - a \frac{T R}{2\pi} = 0$$

$$a M + a' N + b' \frac{T R'}{2\pi} = B$$

$$b M + b' N - a' \frac{T R'}{2\pi} = 0$$

These equations contain the solution of the problem, but are too cumbersome to be worth while solving generally; we will, however, prove the statements made in the lecture before the Civil Engineers.

1st. Compare short circuit and open circuit, that is $R = 0$ very nearly, and $R = \infty$. In the former case we find that work done in the iron is diminished, and if $B = \frac{A M}{L}$ we have the paradoxical result that there are no currents induced in the iron of the cores and no work is required to drive the machine. This, of course, can never actually occur, because R can never absolutely vanish. It suffices to show, however, that the current in the copper circuit may diminish the whole power required to drive the machine to an amount less than the power required to drive the machine on open circuit.

2nd. The other statement related to the effect of the currents in the iron upon the currents produced in the copper circuit. Assume that the effect is a small one, for a first approximation. Neglect it, that is, treat the currents in the iron and the current in the copper as independent of each other, and then see how each would disturb the other.

The first approximation then is

$$\begin{cases} a = \dfrac{A L}{L^2 + \frac{T^2 R^2}{4\pi^2}}; & a' = \dfrac{B N}{N^2 + \frac{T^2 R'^2}{4\pi^2}} \\ b = \dfrac{A \frac{T R}{2\pi}}{L^2 + \frac{T^2 R^2}{4\pi^2}}; & b' = \dfrac{B \frac{T R'}{2\pi}}{N^2 + \frac{T^2 R'^2}{4\pi^2}} \end{cases}$$

If we substitute these in the general equations as corrections, we have

$$\begin{cases} a L + b \frac{T R}{2\pi} = A - \dfrac{B N M}{N^2 + \frac{T^2 R'^2}{4\pi^2}} \\ -a \frac{T R}{2\pi} + b L = -\dfrac{B \frac{T R'}{2\pi} M}{N^2 + \frac{T^2 R'^2}{4\pi^2}} \end{cases}$$

which shows that the disturbing effect of each circuit upon the other is to diminish the apparent electromotive force, but to accelerate its phase.

VI. A very similar problem is that of secondary generators or induction coils, whether used for the conversion of high potentials to low, or the reverse. To treat it generally, taking the magnetisation of the iron cores, which are always used, as a non linear function of the currents in the coils would be a matter of much difficulty; we therefore assume, as is usual, that the coefficients of induction are constants, noting in in passing that this is not strictly the fact, though it is very nearly the fact, when the cores are not saturated and when the lines of magnetic induction pass through non-magnetic space.

Let, then, R r be the resistances of the primary and secondary circuits,
L coefficient of self-induction of the primary,
N coefficient of self-induction of the secondary,
M coefficient of mutual induction of the two circuits,
x and y the currents in the two circuits at time t,
X the electromotive force applied in the primary circuit by an alternate-current dynamo machine or otherwise,

the equations of motion will be

$$\left.\begin{aligned} L x' + M y' + R x &= X \\ M x' + N y' + r y &= 0 \end{aligned}\right\}$$

Various assumptions may be made as to X, but that most likely to be adopted in the practical work of secondary generators is that X is kept so adjusted that

$$x = A \cos. n t \text{ where } n = \frac{2\pi}{T}$$

and to inquire how X will depend on the resistances

$$N y' + r y = n A M \sin. n t$$

* Paper read before the Society of Telegraph Engineers and Electricians on November 13th.

† *Vide* also *Encyclopædia Britannica*, article "Lighting."

Digitized by Google

$$y = \frac{n\,A\,M}{n^2\,N^2 + r^2}\,(-n\,N\cos.\,n\,t + r\sin.\,n\,t)$$

$$X = A\left[\left\{-n\,L + \frac{n^3\,N\,M^2}{n^2\,N^2 + r^2}\right\}\cos.\,n\,t + \left\{\frac{M^2\,n^2\,r}{n^2\,N^2 + r^2} + R\right\}\cos.\,n\,t\right]$$

As in the case of the dynamo machine, the work done in the secondary circuit is greatest when $r = n\,N$. The expression for X serves to show that when the secondary is short-circuited a *lower* electromotive force of the generating circuit is required than when it is on open circuit. In induction coils the electrostatic capacity of the coils themselves has important effects. An illustration of the effect of electrostatic induction is found in the old-fashioned Ruhmkorff coils. These were not wound symmetrically, but in such wise that one end of the secondary coil was on the whole towards the inside, the other towards the outside of the bobbin. In such coils a spark to earth may be obtained from the outside end, but not from the inside. The reason is that the outer convolutions have smaller electrostatic capacity than the inner ones. The terminals may be made to give equal sparks by the simple expedient of laying a piece of tinfoil around the whole coil and connecting it to earth.

VII. Some time ago Dr. Muirhead told me that he had observed that the effect of an alternate current machine could be increased by connecting it to a condenser. This is not difficult to explain: it is a case of resonance analogous to those which are so familiar in the theory of sound and in many other branches of physics.

Take the simplest case, though some others are almost as easy to treat. Imagine an alternate current machine with its terminals connected to a condenser; it is required to find the amplitude of oscillation of potential between the two sides of the condenser. Let $R\,\gamma$ be the resistance and self-induction of the machine, $E\sin.\frac{2\pi t}{T}$ its electromotive force, C the capacity of the condenser, V the difference of potential sought, and x the current in the machine, then

$$C\,V' = x$$

and

$$\gamma x + R\,x = E\sin.\frac{2\pi t}{T} - V$$

whence

$$\gamma x' + R\,x' = \frac{2\pi}{T}E\cos.\frac{2\pi t}{T} - \frac{x}{C}$$

$$x = \frac{\left\{1 - C\gamma\left|\frac{2\pi}{T}\right|^2\right\}\cos.\frac{2\pi t}{T} + RC\frac{2\pi}{T}\sin.\frac{2\pi t}{T}}{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}^2 + R^2C^2\left(\frac{2\pi}{T}\right)^2}\cdot\frac{2\pi E\,C}{T}$$

$$V = \frac{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}\sin.\frac{2\pi t}{T} - RC\frac{2\pi}{T}\cos.\frac{2\pi t}{T}}{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}^2 + R^2C^2\left(\frac{2\pi}{T}\right)^2}\cdot E$$

Amplitude of V is therefore

$$= \frac{1}{\sqrt{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}^2 + R^2C^2\left(\frac{2\pi}{T}\right)^2}}\cdot E$$

Now suppose E = 100 volts, the machine would light up an incandescent lamp of about 69 volts; let $T = \frac{1}{200}$ second, C = 100 microfarads, and $\frac{2\pi\gamma}{T}$ = eight ohms, and $R = \frac{1}{10}$ ohm, all figures which could be practically realised, we have amplitude of V = 80 E roughly, or the apparent electromotive force would be increased eighty-fold.

We now return to the principal subject of the present communication. Some attempts have been made to verify the proposition that two alternate-current machines can be advantageously connected parallel, but I believe, till recently, without success. I had no convenient opportunity for testing the point myself till last summer, when I had two machines of De Meritens, intended for the lighthouse of Tino,* in my hands. I have made no determinations of the constants of these machines, but between three and four years ago I thoroughly tested a pair of similar machines now in use at a lighthouse in New South Wales.* Each machine has five rings of sixteen sections, and 40 permanent magnets. The resistance of the whole machine as connected for lighthouse work (a single arc) was 0·0313, its electromotive force (E) when running 830 revolutions per minute, 95 volts and $\left(\frac{2\pi\gamma}{T}\right)^2$ = 0·197 ohms. It was further remarked that the loss of power was least with a maximum load, as is shown in the following table:—

Power applied as measured in belt	3·1,	4·8,	5·6,	6·5,	5·4
Electric power developed ...	0·7,	3·4,	4·3,	5·7,	3·4
Mean current in amperes ...	7·7,	38·6,	51·7,	73·6,	151

The result illustrates well the conclusion arrived at in Problem V. above.

Last summer the two machines for Tino were driven from the same countershaft by link bands at a speed of 850 to 900 revolutions per minute; the pulleys on the countershaft were sensibly equal in diameter, but those on the machines differed by rather more than a millimetre, one being 300, the other 299 mm. in diameter (about); thus the two machines had not when unconnected exactly the same speed. The pulleys have since been equalised. The bands were of course put on slack as practicable, but no special appliance for adjusting the tightness of the bands was used. The experiment succeeded perfectly at the very first attempt. The two machines, being at rest, were coupled in series with a pilot incandescent lamp across the terminals, the two bands were then simultaneously thrown on; for some seconds the machines almost pulled up the engine. As the speed began to increase, the lamp lit up intermittently, but in a few seconds more the machines dropped into step together, and the pilot lamp lit up to full brightness and became perfectly steady and remained so. An arc lamp was then introduced, and a perfectly steady current of over 200 amperes drawn off without disturbing the harmony. The arc lamp being removed, a Siemens electro-dynamometer was introduced between the machines, and it was found that the current passing was only 18 amperes, whereas, if the machines had been in phase to send the current in the same direction, it would have been more than ten times as great. On throwing off the two bands simultaneously, the machines continued to run by their own momentum, with retarded velocity. It was observed that the current, instead of diminishing from diminished electromotive force, steadily increased to about 50 amperes, owing to the diminished electrical control between the machines, and then dropped off to zero as the machines stopped. Professor Adams will, I hope, give an account of experiments he has tried with me, and on other occasions, at the South Foreland. With De Meritens' machines I regard coupling two or more machines parallel as practically the best way of obtaining exceptionally great currents when required in a lighthouse for penetrating a thick atmosphere.

(Note added 22nd November, 1884).

My attention has only to-day been called to a paper by Mr. H. Wilde, published by the Literary and Philosophical Society of Manchester, Dec. 15th, 1868; also *Phil. Mag.*, Jan., 1869. Mr. Wilde fully describes observations of the synchronising control between two or more alternate current machines connected together. I am sorry I did not know of his observations when I lectured before the Institution of Civil Engineers, that I might have given him the honour which was his due. If his paper had been known to those who have lately been working to produce large alternate current machines, it would have saved them both labour and money.

* The engines, dynamos, lamps, optical apparatus, and lanterns of both these lighthouses have been supplied by Messrs. Chance Brothers and Co.

THE SILENT ELECTRIC ARC.

BY ANTHONY C. WHITE, S.B.

If we take two carbon rods through which a current of electricity of sufficient strength to produce an electric arc is passing and gradually separate them, we shall find that a disagreeable hissing sound will be produced in connection with the electric light. When the separation has reached a certain amount the noise will suddenly disappear, and the arc will remain silent until the carbons are separated enough to open the circuit. The cause of the hissing has never to my knowledge been satisfactorily explained.

In August of 1883, while experimenting upon the electric arc, I made some observations on the silent electric arc to see if it would not throw some light upon the cause of the hissing. The apparatus used in this investigation I am not at liberty at present to describe. The measurements of current strength and E.M.F. were made with an Ayrton and Perry's ammeter and voltmeter.

In the measurements made in August of 1883 I did not measure the separation of the carbons. I have since improved the apparatus, especially the lamp, and have employed a ten-light Weston dynamo in place of the five-light machine first used. The working of the lamp was everything that could be desired. The results of my observations are as follow :—

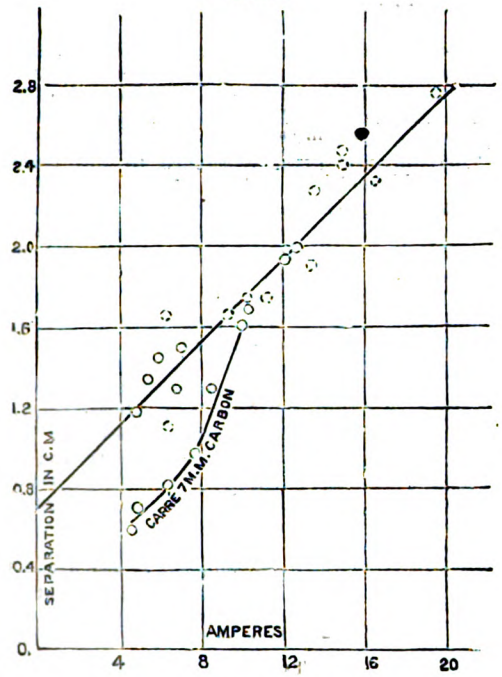
* The columns marked with an asterisk indicate the averages of three observations.

I have plotted curves for some of the measurements. Plate I. shows the increase of separation with the current strength for the silent arc in the case of the Wallace 11mm. carbon and the Carré 7 mm. Plate III. is from a series of measurements made 30th July on the Boulton 11 mm. carbon. Plate II.

Digitized by Google

shows the relation between the resistance and current strength for the silent arc. Points marked o' were obtained from the equation $x\,y = 40{\cdot}8$, which is the equation of a hyperbola. The proximity of these points to the curves proves conclusively

PLATE I.



that it is hyperbolic; and since it is a hyperbola the resistance of the silent arc is inversely as the current strength.

From my measurements I draw the following conclusions:—

1st. The E.M.F. of the silent arc is constant, regardless of the current strength.

2nd. The resistance varies inversely as the current strength.

3rd. The E.M.F. is independent of the size of the carbons.

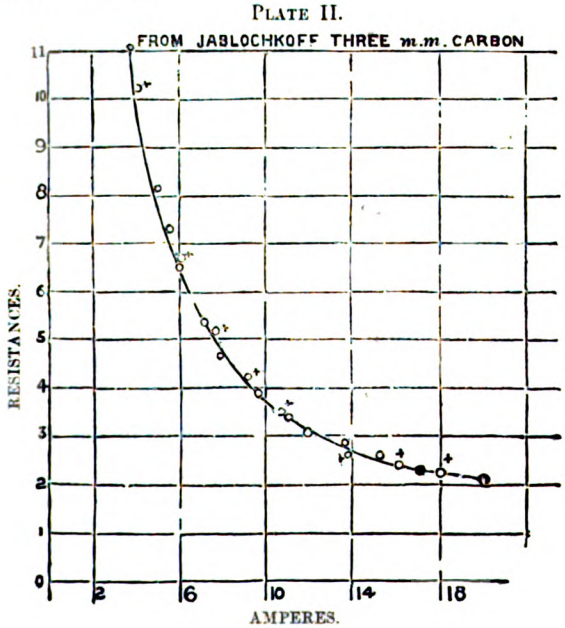
4th. For the same carbons the separation varies in direct ratio to the current strength.

5th. The value of the E.M.F. is somewhat affected by impurities in the carbons.

6th. The separation is considerably affected by impurities in the carbons.

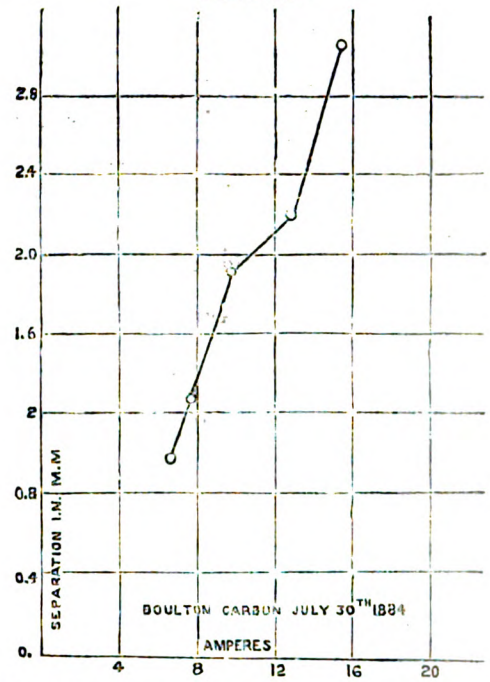
7th. The position for silence is a well-defined point, the E.M.F. falling several volts as soon as hissing begins after the arc has been silent.

PLATE II.



I have never succeeded in obtaining a silent arc with a current less than 3·55 amperes, when the resistance was 10·93 ohms. This was with a Jablochkoff carbon 4mm. in diameter. By examining the curve on Plate II. it will be seen why it is so difficult to maintain a silent arc with a weak current, for a small reduction of the current strength when small will cause a great increase in the resistance of the arc.

PLATE III.



It will be seen by examining the tables that the E.M.F., as a rule, increased somewhat with the current strength. This is due partly to the resistance of the carbon rods. In all the preceding measurements the E.M.F. due to this resistance has not been eliminated. It is evident this error is not a constant, but varies with the current. I do not think a rise of more than two volts can be attributed to the resistance of the carbons. The higher readings, which cannot be accounted for in this way, may be due to impurities.

ON THE ELECTRIC LIGHT.*

BY ALFRED RICHARD SENNETT, A.M.I.C.E.

The production of electricity, and its subsequent conversion into light, is to-day another example of "directing the great sources of power in nature for the use and convenience of man," and, as such, falls within the category of works undertaken by the civil engineer. It is the purport of the author briefly to explain in what electric lighting consists, the relation which it bears to other methods of illumination, and to describe some of the apparatus employed in its production and utilisation. Electric lighting, then, consists in converting energy, whether potential or kinetic, into light through the intervention of that form of energy known as electricity. This transmutation by the ordinary method, namely, by employing a steam engine to give motion to a magneto or dynamo-electric generator, is somewhat circuitous. Nevertheless, although the best engines yield but about one-ninth part of the total energy residing in the coal consumed, and loss may and does take place in the transmission of the kinetic energy of the motor to the generator—in this latter in the transport of the electric energy to the focus of illumination, and, indeed, at the focus itself—yet in point of economy it compares most favourably with all other methods of illumination. The only reason which can be given for this is, that through the agency of electricity a greater concentration of heat can be effected than by any other means, and because the intensity of the light emitted from an incandescent body rises much more rapidly than the temperature. Very different figures have been assigned to the temperature of the poles of the electric arc; thus Professor Rosetti, after a long series of experiments, gives +3,200° to 2,500° Centigrade; Professor Dewar +6,000° Centigrade; Professor Becquerel +2,000° Centigrade. Now, taking the lowest of these, and assuming the law of Becquerel to hold good for high temperatures, each unit of area of the electrode would emit a light 191,000,000 times as intense as that of a body at 916° Centigrade (melting point of silver). The most simple method of

* Paper read at a Supplementary Meeting of the Institution of Civil Engineers.

Digitized by Google

conversion is by chemical action, exemplified in galvanic batteries, the efficiency of which, as will be seen by comparing the energy obtained by the combination of zinc in various cells by Julius Thomsen, with the energy of combination of a given weight of zinc with oxygen, is very high ; but the relatively high price of the fuel consumed, and the fact that the heat procurable from a given weight of zinc is only about one-seventh that obtainable from coal, prohibits its use. Many attempts to attain the end more directly have been made (for example, thermo-electric generators, gas, batteries, &c.), but at present not one is in a position to compete with the dynamic method. Now, since loss is always consequent upon the conversion of one form of energy into another, it should be the aim of the engineer both to reduce the number of conversions and to diminish each to a minimum, so that the highest possible percentage of the original store of energy may be obtained at the focus of illumination. By loss here is meant energy not expended in the desired direction ; of course no actual loss can take place. The conditions of electric lighting may be represented by a simple case of dynamics, for in both the reclaimed energy is due to fall of potential—in the one case electrical, in the other mechanical. Take the simplest example—that of a falling weight—and let the machine in one case be a man, and in the other any dynamic generator of electricity. The man produces a great difference of potential by carrying the weight up, say, a monument ; the other generator effects the same by mechanically cutting lines of magnetic force. The fuel for the first machine is provided by fat and muscular tissues, for the second by the potentiated radiant energy of other ages. This difference of potential is in the one case expressed in pounds, in the other in volts. The weight rests at the top of the monument ; the flagstone offers too great a resistance for it to overcome ; the circuit of the machine remains open ; the cold air offers too great a resistance for it to overcome. Imagine a number of sheets of, say, sackcloth to be suspended horizontally from top to base of the monument ; imagine the external circuit of the machine to be composed of a like number of units of length. The weight is cast off the monument, it overcomes the resistance of each stratum of sackcloth, and forcing its way through, imparts to each a modicum of heat. The circuit is closed, the electromotive force overcomes the resistance of each unit of length, and, forcing a current through, imparts to each a modicum of heat. On the arrival of the weight at the base, it has the same potential as the earth ; on arrival of the current at the other pole it has the same potential as this latter. In both cases the work done, or heat produced, which is the same thing, will have a relation to the amount of fuel consumed dependent upon the efficiency of each machine. The efficiency of the man depends upon his weight ; that of the generator upon dispositions too numerous to mention here. But this heat has been wasted so far as the production of light is concerned, for although a sufficient quantity was present, it was not sufficiently concentrated to produce light. Now reduce the resistance in circuit by diminishing the number of strata of sackcloth, or by lessening the thickness of each. Also reduce the resistance in circuit by diminishing the number of units of length or increasing the sectional area of each ; substitute for the lessened resistance of the sackcloth a sheet of iron, and for the diminished resistance of the conductor an arc ; the weight again falls, and meeting with scarcely any resistance, except at the plate, most of its momentum is utilised in penetrating the iron and producing a flash of light. The current again flows, and meeting with scarcely any resistance, other than that of the arc, most of its energy is used in producing light. There is yet one thing more—the inverse or counter electromotive force of the arc. This may be represented by the momentum of a stone thrown upwards and meeting the falling weight just as it enters the iron plate. Fig. 1 shows this fall of potential when a steam engine is employed. The fall is due to the following efficiencies :—Steam engine, 11 per cent. ; gearing, 95 per cent. ; dynamo-electric generator, 80 per cent. ; cables, 93 per cent. ; and carbons, 94·4 per cent. The ordinate G H represents the potential energy of coal (that is, the energy with which the carbon wishes to unite with the oxygen of the air). In this case let G H represent 1lb. of coal = 800·0 cent.-units of heat × 1,390lbs. = 333·6 h.-p. per minute = 5·56 h.-p. per hour. Under the conditions shown the energy expended in the arc will be 0·4 h.-p., which will yield a light (in an arc of great power) equal to about 800 standard candles for one hour. If the whole energy had been transmitted to the generator, a light equivalent to about 7·420 candles would have been produced, whilst if the whole fall of potential had taken place in the arc, a light of the intensity of about 11,120 candles for an hour would have been the result.

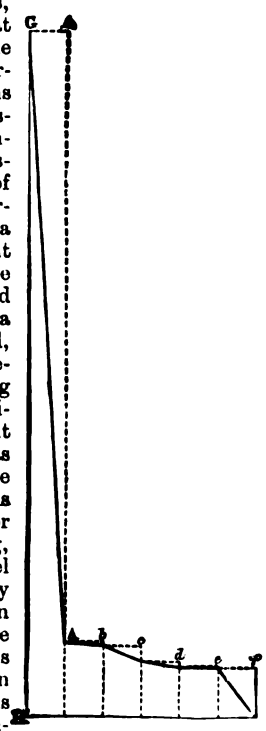


Fig. 1.

The Arc.—Of the several methods of converting electrical energy into light, the two most frequently employed are known respectively as the arc and incandescence methods. The light in the former method—that of Sir Humphrey Davy (1810)—is produced by causing the current to traverse a small space between carbon points. This opposing great resistance to the passage of the current causes intense heating of the electrodes, and light is the result, due, first, to the incandescence of the solid carbon points ; and, secondly, to the stream of incandescent carbon particles which forms the arc. The light emitted by the former, which is by far the more intense, is similar to that of the sun in composition ; whilst that of the latter is extremely rich in the more refrangible rays, and gives to electric light its characteristic tint. On account of this disintegration and oxidation of the carbon electrodes, it is necessary, in order to produce a continuous light, to provide means for automatically feeding the electrodes, and this is generally effected by a piece of mechanism known as a regulator, or arc lamp.

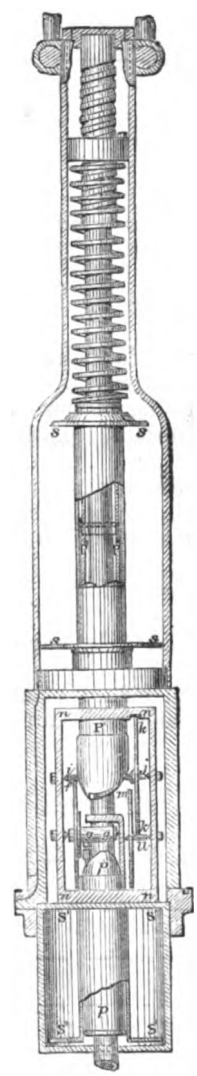

Fig. 2.

Regulation of the Arc.—The following are among the essentials of a good regulator or lamp :—Its working parts should be as few as possible, and easily accessible for cleaning, &c. It should be so simple that repairs to it can be entrusted to workmen of ordinary intelligence. The works should be well covered, and placed above the arc, so as to be proof against the entry of ash and small particles of carbon. It should be capable of being so adjusted as to allow a definite strength of current to pass if one lamp only is to be placed in circuit ; or to maintain a definite resistance of arc—in other words, to preserve a constant difference of potentials between the two electrodes, if several lamps are to be worked in series. If the lamp does not fulfil this requirement, more current will pass, more motive power will be absorbed, heating of the machine will ensue, and the whole system will be subjected to a greater strain than that for which it was originally intended. The moment of inertia of the controlling parts should be small, so that it may promptly respond to any variation in the required conditions. It should be capable of imparting a delicate feed to the carbons at short intervals of time. Its mechanism when not in the act of feeding should be locked, so that no swinging, jarring, or bodily movement of the lamp will cause it to feed with a normal arc. The lamp should be provided with both a coarse and a fine adjustment, in order that it may answer immediately to any sudden lengthening of the arc (such as that, for example, which frequently occurs from the falling off of a portion of the electrodes) without the necessity of waiting for a prolonged action of the fine adjustment.

The number of forms of mechanism which have been devised for the purpose of effecting the necessary feed of the carbons is very great, and it is extremely interesting to trace their development towards perfection. The author will, however, explain only that apparatus appertaining to electric lighting with which he is connected. Diagrams showing the disposition of the parts of the lamps and the method of connection are given in Figs. 2, 3, 4, 5, and 6.

In order to obtain delicacy in the feed, most lamps hitherto have been provided with long trains of wheel-work, with the object of lessening as much as possible the work done by the governing device, and of reducing a comparatively coarse feed of the governing

Digitized by Google

device to a very fine one of the carbons themselves. The feed is generally governed by the movement of heavy armatures or solenoid cores. Two great disadvantages in this method of governing are: first, that the moment of inertia of both the train and the armatures is too great to allow the system to respond to very slight deviations from the required conditions; and, secondly, that as the force acting between the magnet and its armature varies as the square of the distance through which it acts, the power of the governing-device varies greatly with its position. Consequently, when the governing device is actuated by any deviation from the required conditions of the system, it can never cease to act exactly when the required condition has been regained, but must continue to act until a deviation has been produced in the opposite direction. For the governing device the author employs a very light and delicately suspended or balanced electro-magnet, or solenoid, working under the influence of controlling electro-magnets or solenoids. In Figs. 2, 3, 4, 5, and 6, *a*, *b*, *c*, represent the delicately balanced electro-magnet, and to which for brevity the author has given the name "reaction or reciprocal armature." The poles which control the action of this reciprocal armature are formed by the prolongation of the plungers *p*, *p*, and P′, P′, of the solenoids.

The reciprocal armature has not a continuous paramagnetic core, but consists of two cores separated by diamagnetic material. The core *b*, *c*, has wound upon it a wire forming a continuation of the wire upon the solenoid S′, S′, S′, S′, which is so connected as to form a shunt or derived circuit to the arc; that is, the current

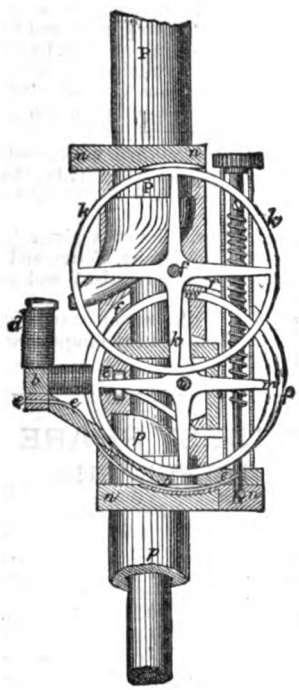

FIG. 3.

flowing in the circuit thus formed does not pass through the arc. The arrangement is very similar to the by-pass upon an ordinary gas-main. The wire coiled upon *a*, *b*, virtually forms part of the main circuit, namely, the circuit through both the arc and the by-pass, although for constructional reasons it is made to form a derived circuit to the solenoid *s*, *s*, *s*, *s*, in order that a much finer wire may be employed. Attached to the diamagnetic portion of the armature is the brake-spring *e*, *e*, *e*. The plungers *p*, *p*, and P′, P′, project from the top and bottom of the gearing frame, and play within the solenoids *s*, *s*, *s*, *s*, S′, S′, S′, S′. Consequent upon the strength and sensibility of the reciprocal armature, the author has been enabled to employ a very short train; it consists of the first wheel *f*, *f*, connected to the pinion *g*, *g*, which gears with the rack through the intervention of a rachet wheel, in order that the rack may be raised without the necessity of revolving the train backwards. This first wheel gears with the pinion *i*, keyed to the arbor *j*, upon which is mounted the wheel *k*, *k*, gearing with the small pinion *l*, *l*. This latter carries the aluminium brake-wheel *m*, *m*, the total weight of which, together with the pinion, is about one-tenth of an ounce.

The action of the lamp is as follows:—when no current is flowing the gearing frame *n*, *n*, *n*, *n*, rests nearly upon the bottom of the framing of the lamp, in which position the carbons are in contact. Upon a current passing through the lamp the plunger P, P, is drawn up into the solenoid *s*, *s*, *s*, *s*, and by this motion the arc is formed; the current now flows through *s*, *s*, *s*, *s*, *a*, *b*, and the arc, and by the other route through S′, S′, S′, S′, and *c*, *d*. The directions of winding are such that repulsion takes place at *a*, and attraction at *c*, and these may be made to just balance each other with a given difference of potentials between the electrodes. In order, however, that the lamp may be adjusted to maintain any length of arc at will, the attraction at *c* is made to be slightly in excess of the repulsion at *a*, in order that a certain amount of torque may be imparted to the system, the amount of which, however, may be regulated by the tension of an adjusting spring.

By this means the author has been enabled to employ a governing device, whose power and sensibility are independent of its position in relation to the controlling poles, and thus the objections above referred to have been eliminated, the motion of the feed-mechanism being arrested immediately the required conditions are fulfilled. In order to reduce to a minimum the electrical energy

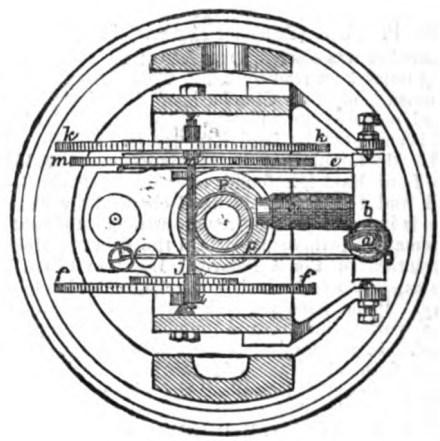

FIG. 4.

necessary to perform the mechanical operations of the lamp, the solenoid *s*, *s*, *s*, *s*, is assisted in its work by a suspension spring, or by being partially balanced, and this increases the sensibility of the lamp, since it causes it to respond immediately to any sudden lengthening of the arc by the bodily movement of the gearing frame and train.

It is obvious, in order to make the efficiency of an arc lamp as high as possible, that care should be taken, first, that the resistance introduced into the main circuit be as small as possible, and secondly, that the smallest possible amount of energy be allowed to flow through the shunt or by-pass circuit. The resistance of this latter, then, should be as great as possible, and by the employment of the reciprocal armature, the author has been able to raise this resistance to 2,000 ohms. On account of the resistance of the shunt, or by-pass being so great, it is almost impossible to burn it, especially if the generating plant be provided with suitable regu-

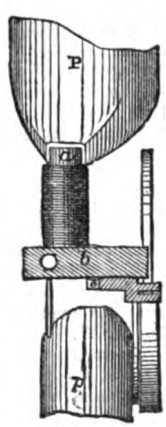

FIG. 5.

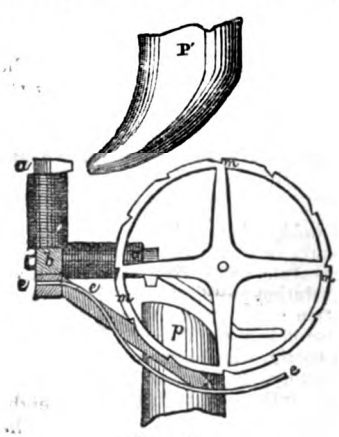

FIG. 6.

lating appliances. The burning of the shunts of differential lamps has hitherto been a source of some trouble.

A peculiarity of this lamp consists in the fact that it will continue to feed even though the shunt be burned. In order that it may do this, a little lever is generally attached to the cross-bar *b*, *b* (Figs. 2, 3, 4, and 5) of the reciprocal armature, and projects in the opposite direction to the brake spring *e*, *e*, *e*. Projecting from the rigid frame of the lamp is a stop, so placed in relation to this lever, that when the gearing frame *n*, *n*, *n*, *n* descends, it engages with the lever and thus removes the brake. The action of the lamp after the burning of the shunt is easily seen. The gearing frame, when a normal strength of current is flowing, is held up against the top of the rigid frame. As, however, the

Digitized by Google

length of the arc becomes greater, and its resistance in consequence increases, the gearing frame slowly descends, and after a time the lever engages with the stop, and the break being thereby removed, the mechanism feeds, but ceases to do so as the strength of current increases, and the gearing frame gradually rises. The rack instead of being solid is formed of a drawn brass tube, and the arbors and the fulcrum of the reciprocal armature instead of being supported in bearings are carried upon hardened steel points. The employment of the latter greatly increases the life of the motion.

(TO BE CONTINUED.)

PHYSICAL SOCIETY.—Nov. 22.

The President (Professor Guthrie) in the chair.

Mr. James Bewsher was elected a member of the society.

The following notes were read by Mr. R. T. GLAZEBROOK, M.A., F.R.S., 'On the Permanence of some Standards of Electrical Resistance." The author has had occasion to compare with ten standard B.-A. units a coil which had been tested by Lord Rayleigh in 1882, the coil then being two years old. He found that its resistance was 9·98335 B.-A.-U. at 14°05C., while Lord Rayleigh found the value 9·98330 B.-A.-U. Thus either the coil and the standards have changed by exactly the same amount, which is improbable, for they are wires of different thickness, or they have all remained permanent. "On the Effect of Moisture in Modifying the Refraction of Plane Polarised Light by Glass." The author described some experiments he had been engaged in lately at the Cavendish Laboratory. Plane polarised light is made to fall on a plate or a wedge of glass at various angles, and the position of the plane of polarisation determined. It is found that this depends greatly on the hygrometric condition of the air in the neighbourhood of the glass. If moist air be blown on to perfectly clean glass the plane of polarisation of the emergent light is displaced from its normal position in one direction, while if dry air be blown it is displaced in the opposite direction. At an angle of incidence of 60° the difference between the two positions is from 6′ to 8′. If, however, the glass be not perfectly clean, the effect of moisture is *at first* the same as that of dry air, though on stopping the draught an opposite effect is observed. The author assigns as the cause of this the heating of the surface, which, as Magnus discovered, is produced by a draught of moist air. He finds, on repeating Magnus's experiment, that the heating is not produced if the glass be clean, and he shows by an independent experiment that slight local heating does produce an effect on the plane of polarisation in the same direction as that due to the dry air.

Mr. Glazebrook also exhibited a spectrophotometer, described by him in a paper read before the Cambridge Philosophical Society (*Proc. Phil. Soc.*, Vol. IV., part 6), and made by the Cambridge Scientific Instrument Company from his design.

A note "On a Point in the Theory of Pendent Drops," by Mr. A. M. Worthington, was read by the SECRETARY (Mr. Walter Baily). This was a note upon a paper recently communicated by the author to the Royal Society upon the measurement of the surface tension of a liquid from observations of the forms assumed by pendent drops. By making a measurement of a horizontal section of such a drop, and of the angle made by the tangent plane to the surface at the line where the section meets the surface, with the horizontal, and knowing the density of the liquid, sufficient data are obtained to determine its surface tension.

Professor PERRY, remarking upon this paper, gave an account of some researches upon the subject, in which, some years since, he had assisted Sir William Thomson. On the usually accepted theory of "surface-tension" based upon the behaviour of liquids in capillary tubes, at every point of the surface of a liquid the equation

$$kp = \frac{1}{R} + \frac{1}{R'}$$

must hold, where p is the pressure at that point or the difference of pressures on the two sides of the surface, R and R′ the two principal radii of curvature, and k a constant. In the case of a drop whose surface is one of revolution about the vertical, the contour may be drawn from the equation; this was done, and the theoretical drawings were made of a number of drops. These have since been compared by Sir W. Thomson with enlarged photographs of actual drops, and the results are highly satisfactory. This law no longer holds in the case of a drop at its "critical point," or that point when it is about to fall, since here dynamical action comes in.

Mr. BAILY also read a paper by the same author "On a New Capillary Multiplier." This is an apparatus for the measurement of surface tension, and is a modification of one used by M. Despretz. From one extremity of the arm of a balance is suspended a roll of platinum foil, consisting of a strip 50 centimetres long and five or six centimetres broad rolled up, the successive convolutions being prevented from touching by rolling up with the foil a number of small pieces of hard glass tubing about two millimetres diameter which occupy the upper part of the helix, and preserve the form of the lower part. The coil is cleaned by igniting it in a Bunsen flame, and then suspending it with its lower end in the liquid to be examined. The increase in weight corrected for the part of the coil immersed is due to the fluid rising between the convolutions. From this the surface tension is readily calculated.

Mr. HILGER described a new solar eye piece. In Professor Pickering's eye piece there are two rectangular prisms of glass of slightly different refractive indices. The light of the sun undergoes partial reflection at the surface separating the two prisms, the ratio of the reflected to the incident light diminishing with the difference between the refractive indices. It is found, however, that such a prism under a high power always gives a double image due to the two glass surfaces, it being practically impossible even under enormous pressure to bring them into true contact. To obviate this Mr. Hilger makes the second prism of Canada balsam, which gives the most satisfactory results, the image being pure and single.

LEGAL.

Edwards v. Dennis, re "Neptune" Brand.

This action recently came on for trial at the Liverpool Assizes before Mr. Justice Smith and a special jury. Mr. Charles Russell, Q.C., Mr. French, and Mr. Lawrence, instructed by Messrs. Whitby, Maddock and Co., of Liverpool, appeared for the plaintiff; and Mr. Henn Collins, Q.C., and Mr. Cutler, instructed by Messrs. Van Sandau and Co., of London, appeared for the defendants. At an early stage of the trial it was agreed to discharge the jury, and to leave all matters of fact and law to the judge. This action (which involves very important questions of trade and law) was brought by Mr. Edwards, of Birkenhead, to restrain Mr. W. F. Dennis, the London representative of Messrs. Felten and Guilleaume, of Mulheim-Cologne, Germany, manufacturers of wire, from using the Neptune brand. The facts are shortly as follow:—In the latter part of 1878 Messrs. Cromar, Scott and Co., of Liverpool, manufacturers of iron sheets and jobbing galvanisers, registered as a trade mark in Class 5 a device consisting of the figure of the god Neptune, with the word "Neptune." About 18 months since Mr. Edwards acquired the business of Cromar, Scott and Co., including the trade mark in question. In 1880 Messrs. Felten and Guilleaume registered for steel wire and iron wire (Class 5) a trade mark, consisting of a Trident and the word "Neptune." It was elicited on cross-examination of the plaintiff and his witnesses that neither he nor Messrs. Cromar, Scott, and Co. had ever manufactured wire, but that over a period of ten years Messrs. Cromar, Scott, and Co. had galvanised small lots of wire of other manufacturers, the entire quantity of wire so galvanised not exceeding five to ten tons, and that they had not galvanised any wire for the last five years, and that Mr. Edwards for several years had been cognisant of the defendants' brand.

On behalf of the defendant evidence was given to show the enormous quantity of wire manufactured by Messrs. Felten and Guilleaume from the year 1877, and which had been advertised and sold by them under their Neptune brand.

The further consideration of the action stands over until the return of Mr. Justice Smith to London, when the important question of law will have to be argued before him.

NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 28th Nov. amounted to £3,872.

EARTHQUAKE SHOCKS AT GENEVA.—Several violent shocks of earthquake were felt at Geneva shortly after 11 o'clock on the night of the 27th ult.

LIGHTING OF THE MANSION HOUSE.—The Hammond Company has obtained the contract for the electrical lighting of the Mansion House, London.

THE "GREAT EASTERN."—This steamship, before she sails for the New Orleans Exhibition, is to be fitted up throughout with incandescent electric lamps.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts for the month of November were £1,736 against £1,781 in the corresponding period of last year.

THE EASTERN TELEGRAPH COMPANY.—The Eastern Telegraph Company's traffic receipts for the month of November, 1884, amounted to £55,640, and to £49,390 in the corresponding period of 1883.

HEALTH EXHIBITION AWARDS.—Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street, E.C., have been awarded a gold medal by the Jury Commission of the Health Exhibition for incandescent lamps.

TELEGRAPH OPERATORS IN GERMANY.—While, in the Fatherland, lady operators are content with £4 a month, men refuse to accept such a low salary, especially as they have to be at their posts many hours in the day.

NEW TELEGRAPH OFFICE.—The name Santiago (Cape de Verde Islands) should be added to the list of telegraph offices. Telegrams can be sent to Santiago by the Eastern, the Direct Spanish, and the Submarine Telegraph Companies.

ELECTRIC LIGHT AT VIENNA.—The offices and printing rooms of the *Neues Tageblatt* of Vienna are lighted by 300 Edison incandescent lamps fed by an Edison dynamo. The lamps in the offices are movable, with supple leads.

ELECTRIC LIGHT IN PICTURE GALLERIES.—The central hall of the Corporation Galleries of Glasgow, which at present contains the valuable collection of paintings lent by the Marquis of Bute, is now illuminated with electric light.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts for the week ended 28th Nov., 1884, were £2,436, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

INDIA RUBBER STAMPS.—We have received from Mr. E. Ellison, of 41, Glover-street, Leeds, catalogues and samples of his improved rubber type and stamps, which, for both office and domestic uses, are rapidly becoming almost indispensable.

ELECTRIC LIGHT IN CHELSEA.—The Chelsea Electricity Supply Company notify their intention of applying to the Board of Trade for a Provisional Order enabling them to produce, store, and supply electricity within the parish of Chelsea.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts for November amounted to £22,800; from 1st January to 30th November they amounted to £257,480; and in the corresponding months of 1882 and 1883 to £223,863 and £236,469 respectively.

EASTERN EXTENSION AUSTRALASIAN AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company, including subsidies, for the month of November, 1884, amounted to £42,286, and to £36,719 in the corresponding period of 1883; increase, £5,567.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 30th Nov. are £2,333, as compared with £2,340 in the corresponding period of 1883. The August receipts, estimated at £4,835, realised £4,909.

ELECTRIC LIGHT IN FRANCE.—Edison lamps have lately been installed at the following works in France:—50 at Toffin's lace manufactory, Caudry; 40 at Chaffrée's foundry, Le Mans; 50 and 8 regulators at Cointraux' distillery, Angers; and 25 at Lorthillois' Spinning Mills, Tourcoing.

ELECTRIC LIGHT AT MADRID.—Gas is dear in the Spanish capital because of the high rates of carriage for coal and the want of market for the sub-products of the gas works. There is a movement for establishing a central station with two alternate-current Gordon dynamos supplying 12,000 lamps.

SIMULTANEOUS TELEGRAPHY AND TELEPHONY.—The inventor of this system, now being applied throughout Belgium, M. Van Rysselbergh, director of the Brussels Observatory, has been appointed consulting electrician to the Department of Railways, Posts, and Telegraphs, and also made chevalier of the Order of Leopold.

A NEW LAMP.—An incandescent electric lamp has been invented by Mr. James W. Benson, of North Adams, Mass. It is constructed with a spring pawl attached to the globe cap and engaging with ratchet teeth formed upon the outer surface of the insulating ring, so the globe will be locked against accidental displacement.

INDUCTION AT TEMESVAR.—Besides the difficulties recorded last week, the leads for the electric light at this Hungarian town were found to exert an injurious influence on the telephone conductors, so that the two companies agreed to alter the course of the wires in several places. Still, we learn the evil is only partially remedied.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of November was 2,745, estimated to produce £2,475, against 2,866 messages, producing £2,580 in the corresponding month of last year. The traffic receipts for the month of August, estimated at £2,375, realised £2,515.

COMPAGNIE INTERNATIONALE DES TELEPHONES.—As a sufficient number of shareholders to constitute a legal assembly did not attend the special general meeting called for the 29th Nov., notice is given of another special meeting, to be held on 18th Dec., at 24, Rue des Douze Apôtres, Brussels. The chief business is the reduction of the nominal capital.

AWARDS AT TURIN.—In addition to the ordinary medals awarded by the jury of the Turin Exhibition, four gold medals of higher value have been placed at their disposal by the Italian Minister of Public Instruction. One has been given to Professor Ragona, director of the Modena Observatory, for the electrical instruments invented and exhibited by him.

ELECTRIC SEARCH LIGHTS BEFORE SUAKIM.—Our Paris contemporary *L'Electricité*, which often gives a view of some application of the electric light, gave last week a representation of the powerful search light on board one of H.M. ships,

Digitized by Google

which rendered great service in repelling night attacks, in avoiding shoals, and in aiding the gunners to direct their fire.

PNEUMATIC TELEGRAMS IN PARIS.—The telegraph service within the Paris fortifications will be performed entirely by pneumatic tubes from 15th inst. Messages must be written on stamped forms, at the following prices:—Card-telegram, 30c. (3d.); ditto with answer prepaid, 60c. (6d.); closed telegram of any number of words, 50c. (5d.); ditto with reply prepaid, 1f. (10d.).

THE TELEGRAPH IN HUNGARY.—It appears from the returns of the Minister of Communications that the length of telegraph lines in Hungary at the end of last year was 16,223 kilometres (10,080 miles), the wire measuring 59,149 kilometres (36,754 miles). There were 542 State telegraph offices and 706 belonging to railway companies. The persons employed numbered 1,442 men and 223 women.

ELECTRIC LIGHT IN AUSTRIA.—It is reported that the Oesterreichische Nordwestbahn is about to adopt the electric light at Königsgrätz Station, which is 1,100 metres (3,280ft.) long. The cost of installing twelve 1,000 candle arc lamps is estimated at 24,000 florins (£2,400); and the expense of maintenance at 5,800 florins (£580) yearly, while a hundred paraffin lamps giving a light of 2,400 candles cost 6,500 florins (£650).

INVENTORS' INSTITUTE AND THE PATENT ACT.—The meeting on Monday next, 8th inst., will be devoted to the discussion of the Patent Act of 1883, section by section, commencing with Part I., Section I., the chair being taken at 8 p.m. by Vice-President Admiral Selwyn. The discussion will be continued on 12th Jan., 1885. Gentlemen, not being members, who wish to attend should apply to the Secretary, Inventors' Institute, Lonsdale-chambers, Chancery-lane, W.C.

WEATHER FORECASTS BY TELEPHONE.—*Le Franklin* says that, by observing and comparing the sounds emitted by a telephone connected by leads with two iron bars, stuck into the ground a few metres apart, it is possible to have an indication of the coming weather, sometimes ten to twenty hours in advance. In the case of a thunderstorm, especially, a noise like that of shrivelling leaves increases until a flash of lightning occurs, when it resembles that of rain or hail falling on glass.

CATALOGUE.—We have received the monthly price list of new machinery issued by Duncan Brothers, engineers, 32, Queen Victoria-street, E.C.; it is now illustrated by permanent carbon photos. This firm recommends the use of the "A B C Telegraphic Code Book" to firms ordering in a hurry by cable. By permission of the publishers, they give a table of code words for several banks, and selected phrases applicable to the list, as well as a code word for each of their specialities.

ELECTRIC LIGHT IN CARRIAGES.—This application of electric light, which has frequently been seen in Paris lately, has now been imported into England, as we read that a private one-horse brougham, well equipped, drove along one of the principal thoroughfares in London on Wednesday evening, lighted throughout by means of electricity. A brilliant star shone on the horse's forehead, another on the coachman's hat, and a third at the back of the carriage. If we mistake not these are Trouvé's lamps, recently noticed in this journal.

UNIT OF ELECTRICAL RESISTANCE.—For the time being, as decided by the International Congress of Electricians, which met at Paris on 3rd May last, the ohm, or unit of electrical resistance, is the resistance of a column of mercury 1 square mm. in sectional area and 106 centimetres long, at the temperature of melting ice. M. Jamin has brought to the notice of the Paris Academy of Science an instrument, devised by M. René Benoît at the instance of the Minister of Posts and Telegraphs, for giving the exact dimensions of the tube containing the column of mercury.

PARIS ELECTRICAL EXHIBITION, 1885.—By way of completing the note in last issue, this exhibition will be held at the Paris Observatory in a series of rooms which the director, Admiral Mouchez, has placed at the disposal of the Société Internationale des Electriciens. French and foreign electricians, whether members of the society or not, are invited to exhibit; and there will be no expense beyond the carriage and arrangement of articles sent. Applications for space must be made by 25th inst. to the President of the Société Internationale des Electriciens, 3, Rue Séguier, Paris.

SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS.—The annual general meeting for the election of council and officers for 1885 will be held at the Institution of Civil Engineers on Thursday, December 11, when a paper will be read on "Electricity in America," by W. H. Preece, F.R.S., Past President. The new officers for election at the next meeting are:—President, C. E. Spagnoletti, M. Inst., C.E. Members of Council: Major R. Y. Armstrong, R.E., Professor George Forbes, F.R.S.E., and Joseph W. Swan. Associate Members of Council: Lieut-Colonel A. C. Hamilton, R.E., O. E. Woodhouse, and Alexander Pelham Trotter.

FOLLY, OR GLORY?—In the telegram containing the text of Lord Wolseley's address to the troops, Colonel Stewart's ill-fated enterprise is spoken of as one of "unusual danger and folly." Obviously there is some mistake here; and the *Pall Mall* suggests that "peril" is probably meant, as it might "easily be read for 'folly' in Morse code." Our contemporary is misinformed. These two words have not the remotest likeness in Morse code, besides constituting a tautology not likely to be committed by Lord Wolseley. We suspect that the error is one of sound, in which case "glory" would be the most probable correction. Even in Morse code "glory" is much more like "folly" than "peril."

RAPID INSTALLATION.—The ease and celerity with which temporary installations of electric light can be made has just been exemplified by Messrs. Woodhouse and Rawson, who recently lighted up Lady Filmer's residence at Maidenhead, utilising Colonel Fremantle's dynamo and engine, a quarter of a mile distant. The work was only commenced at about eleven o'clock on the preceding morning; but the whole of the cable was run and the lamps were fitted up in time for the dance without any hitch, the lighting being perfectly steady during the whole evening. People having their houses permanently lighted by electricity can thus, by lending their currents on occasion, confer a considerable benefit upon their friends, as the electric light, owing to the absence of heat, greatly enhances the comfort of the guests at a dance, besides adding brilliancy to the decorations.

PARIS EXHIBITION, 1889.—The President of the French Republic has issued a decree that a universal and international exhibition of industrial products shall be held in Paris from 5th May to 31st October, 1889. A second decree appoints a commission of thirty-three members for carrying the scheme into effect, with M. Antonin Proust as president, and M. Tesserenc de Bort and M. Eugène Spuller as vice-presidents, the other members being high functionaries and the presidents of

Digitized by Google

large syndical associations. A project has been submitted to the commission for including in the area of the exhibition, not only the Champ de Mars and the Trocadero, but also the Esplanade des Invalides and the Palais de l'Industrie, giving a space of 400,000 square metres (4,305,720 square feet) more than in 1878. It is said that Germany will not only participate, but has also used its good offices to secure the participation of other countries.

THE CREIL EXPERIMENTS.—It has been decided to use a cable, with core of silicious bronze, supplied by M. Lazare Weiller, manufactured under the Berthoud and Borel patents, of which the Kinetic Engineering Company are the sole licensees in England. An order has been given for 78,000 metres (49 miles) of this cable to be delivered as soon as possible. It is calculated to carry a current of 20 amperes with an E.M.F. of 7,500 volts, equal to 150,000 watts or 200 horse-power. We learn from the *Bulletin* of the Cie Internationale des Téléphones that testing some of the machines has shown the necessity for modifying the collectors, which did not answer their purpose with the currents of high tension employed. The weight of steel and cast iron in each receiver is about 4 tons, independently of the coil; and M. Marcel Deprez has found that the friction of the shaft alone, running light, absorbs 20 horse-power.

IMITATION OF ELECTRICAL PHENOMENA.—In an article in the *Journal de Physique* on "Imitation by Liquid or Gaseous Currents of Electrical and Magnetic Phenomena," M. C. Decharme, after passing in review the mechanical, physical, chemical, and physiological effects of these currents, comes to the following conclusion:—After having initiated, by means of liquid or gaseous currents, in numerous experiments, the principal phenomena of static or dynamic electricity of electro-chemistry, and even of electro-physiology, I feel justified, from analogy of the effects, in believing the analogy of the causes; for instance, that the electrical (or magnetic) phenomena are assimilable to hydro-dynamical phenomena; that is to say, electricity, under the form of current (of ether or of ponderable matter) is analogous to a liquid current, and, in the state of tension, is analogous to a certain quantity of liquid issuing in the form of a jet.

TECHNICAL HANDBOOKS.—Messrs. Symons and Company, of Bouverie-street, E.C., are bringing out some new hand-books for students and practical engineers, called "The Specialist's Series," edited by Dr. Paget Higgs and Professor Charles Forbes. It is intended to impart information on recent technical subjects, in a manner suited to the average intelligence, and in language "to be understanded of the common people." Each volume is to be written, as far as possible, by an independent author, "unflavoured with the taint of commercial advocacy," and giving the results of practical experience. Vol. 1, on Dynamo and Magneto-Electric Machines, by Paget Higgs, LL.D., D.Sc., is now ready, and contains observations on electrical storage, so far as it may be considered as an auxiliary in regulating the current of dynamo-electric and magneto-electric machines. Other volumes on gas engines, ballooning, primary batteries, and arc and incandescent lamps will shortly be issued.

ELECTRIC LIGHT IN MILLS.—The *Journal of the Society of Dyers and Colourists* says:—"It is interesting to know that the electric light is gradually being introduced into the mills and dye-houses in Bradford. At the wool scouring works, where the men have to work all night, the light is greatly appreciated, not only on account of the better light which they have to work by, but also because the air is so much cooler and purer than when gas is burning. In the dye-houses the arc light is used chiefly for 'matching shades,' and is, as a rule, very reliable, especially if none but good carbons be used, as a bad carbon causes sputtering and flickering which makes the light change from a white to a violet tone, and *vice versâ*, and so gives a wrong impression of shade to the dyer. The incandescent lamp is not much used for matching shades, as the light is too yellow, but it is very useful in grey rooms, cleaning rooms, &c., where benzine is used, and in any place where there is much danger of fire."

TELEPHONE DEVELOPMENT.—On Tuesday afternoon, the Postmaster-General received in the Conference Room of the House of Commons a deputation consisting of Sir Massey Lopes, M.P.; Mr. Macliver, M.P.; Mr. Puleston, M.P.; and Mr. Clarke, Q.C., M.P., on the above subject. Memorials were presented on behalf of the Port of Plymouth Incorporated Chambers of Commerce, the Plymouth Mercantile Association, and the Devonport Mercantile Association. The memorialists comprised merchants and traders carrying on business in Plymouth, Stonehouse, and Devonport, and it was pointed out that the present exchange at Plymouth had only forty-two subscribers, and was therefore of little or no use to them. They desired that Stonehouse and Devonport, with Plymouth, should be considered one town for telephonic purposes. The Postmaster-General replied that he had no doubt the department would send some one to the places mentioned to make inquiries, and that he would give the matter due attention.

SCIENCE AND RELIGION.—A company is at present fixing a number of microphones in Dr. Talmage's Tabernacle, Brooklyn. They are to be connected by wire with the houses of certain members of his flock, who will thus be enabled to hear the discourses of the great "pounder and expounder," as an American journal calls him, when circumstances prevent them from being personally present among the congregation. Dr. Talmage possesses a voice of uncommon power, and it has been calculated that with the aid of a sufficient supply of microphones he would be quite capable of filling the Brooklyn Academy of Music, Plymouth Church, Madison-square Gardens, and three other auditoriums, in addition to his own tabernacle. One of the promoters of the undertaking thinks it is destined to inaugurate a revolution in the "preaching trade." Every other trade, he says, has to compete with machinery, and all skilled labour has thereby advanced; "while religion has stood under the old rule of one minister to one church." The time is near at hand, he predicts, when twelve clergymen to each denomination "will cover Brooklyn thoroughly;" and when Dr. Talmage, in particular, will be preaching to twenty congregations every Sunday.

NEW YORK.—The first experiment with electricity as a motive power on the elevated railroads will be made on the Second Avenue line. A central rail twenty pounds heavier than those now in use will be laid between the rails from Chatham-square to the Harlem River terminus. Current will be conducted from the dynamos to the central rail by a large wire. The rail will be insulated, but the present track will remain as at present. All the electric railway companies will be allowed equal facilities for experiments with the motors, and the expense of laying the third rail will be divided between them. A commission to be selected by the companies will decide on the relative merits of the inventions. The regulation of the speed of trains, it is said, will be less difficult with electricity than with steam. Trains can be stopped more quickly, and at all

Digitized by Google

times will be under more perfect control. They will be run with increased safety and less noise, while smoke and cinders will be avoided altogether. The cost of working the roads will be greatly reduced by the use of electricity if the experiments should be successful. Representatives of the electric railway companies say that it will not take more than two months to prepare for the proposed test on the Second Avenue line.

THE ORIENTAL TELEPHONE COMPANY.—An extraordinary general meeting of this company, convened by requisition of the shareholders, is to be held at noon on 22nd inst., at Cannon-street Hotel, with the following objects, viz. :—(1.) To consider the propriety of appointing, and if thought desirable, to appoint a committee of investigation, to examine into the affairs of the company, with power to inquire into and report upon all agreements effected with subsidiary and other companies. (2.) To increase the number of directors by appointing five additional directors or any less number, such increase not to involve any increase of the directors' remuneration. To meet this action on the part of the shareholders the directors propose to submit the following resolution :—"That Clause 58 of the company's Articles of Association be repealed, and that in lieu thereof the following shall henceforth stand and be Article 58," that is to say, "The remuneration of the directors shall be £500 per annum, and in any year in which an annual dividend of over 5 per cent. per annum is paid upon the amount of the capital, for the time being paid up, or deemed and taken as paid up and entitled to dividend, an additional sum of £250 for every one per cent. per annum of dividend paid over and above said dividend of 5 per cent. ; provided always that in no event shall the remuneration of the directors exceed the sum of £2,500 per annum. The remuneration shall be divisible among the directors as they shall determine."

THE GULCHER COMPANY.—This company has lately installed twenty-four 800-candle and two 2,000-candle arc lamps, supplied by a No. 5 dynamo, for Messrs. A. Ransome and Co., of Chelsea ; and ten 800-candle and six 2,000-candle arc lamps, supplied by a No. 4 machine, in the foundry of Messrs. Ransome, Josselyn, and Woods, of Battersea. The gas has been entirely superseded in the large erecting shop (180ft. long by 40ft. wide) of the Coalbrookdale Company, by one 3,000-candle and two 1,000-candle arc lamps, supplied by a No. 1 dynamo ; and although the latter is driven by the same engine as the shafting, the power absorbed by which is not at all constant, the light is remarkably regular. The Gülcher Company has added to the electric lighting plant of the Patent Shaft and Axletree Company, Wednesbury, which now consists of five 3,000-candle and six 2,000-candle arc lamps supplied by a No. 4 dynamo. The same company is lighting a pit mouth of the Tir Pentwys Colliery Company in Wales with a 3,000-candle arc light, which has taken the place of large fires consuming from 10 to 15 cwt. of coal nightly, while the offices are lighted by incandescent lamps, all being supplied by a No. 1 compound-wound dynamo. The rag-sorting department of Messrs. E. Fox and Sons' paper mills at Dewsbury is lighted by thirty-two 20 candle incandescent lamps, supplied by a No. 1 dynamo, while the yard is illuminated by an arc light. The Gülcher Company has also been instructed to light with incandescent lamps the saw mill of Messrs. J. and C. S. Young, of Salisbury, who have ample power and anticipate a great saving of expense.

DEATH AT THE WIRE.—Two cases of telegraph operators dying at their posts have lately been reported from America in the unsentimental phraseology peculiar to Transatlantic journalism. "Ned" Cummins, employed in an office in Virginia, was engaged in "receiving" a press report when he signalled to the operator at the other end : "Been spitting blood, take it easy." Directly afterwards the poor fellow dropped from his chair dead, but—if it be not brutal to say so—there was no great delay to the press report, for very shortly afterwards another hand was secured, who wired to the "sending" clerk these words :—"Cummins just died ; I'm his substitute ; go ahead after 'address,'" this being the last word written by Cummins when the grim ferryman beckoned him. The other case was of one Monk Monroe, who finding himself in the middle of his work stricken by the "blindness of death," had just time to signal along the wire, "Send a doctor, I am going up the hill," and he was "relieved" for ever. He was found with his hand upon the "key." We believe that this evil is a growing one, especially as three cases of insanity are reported by a Scotch contemporary to have occurred at the Edinburgh office only this year. We also believe that it arises chiefly from the concentration of the mind necessary in taking down by sound. Human beings are capable of concentrated effort for a certain length of time, but cannot, like machines, or Tennyson's brook, "go on for ever." The remedy is to be found in reasonable hours, change of occupation, and one good holiday in a year to recharge the human battery.

ELECTRICITY AND DENTISTRY.—Electricity has become such a useful aid to the dentist, chiefly in America, where the chief applications have been invented, that many leading practitioners now regard it as indispensable. The electric mallet, invented by Dr. Bonwill, has now been in use about ten years, and it has lately been improved by Dr. Webb. It is actuated by a special four-cell battery exactly adapted to the power required, and has the great advantage that the blow is delivered upon the packing instrument (for stopping teeth) just at the point where its force is greatest, because the attraction of the magnets constantly increases, as the mallet approaches them, until the circuit is broken. An electric dental engine, for drilling, filing, and polishing teeth to be stopped, has lately come into use, driven by the Electro-Dynamic Company's double-induction electric-motor and automatic battery. It is stated that, with sufficient battery current, the motor is so powerful as to be able to lift two thousand times its own weight one foot per minute, and that the drill may be rotated at 10,000 revolutions per minute. The battery consists of six 1-gallon cells with two carbons and one zinc in each, and an automatic device for removing the electrodes from the fluid when not in use. A switch-board is provided for those who run the drill and the mallet with the same battery. But what will probably be found the electrical invention of the greatest use to dentists is the mouth lamp and mirror. This consists of a small incandescent lamp, fixed in a resistance handle for regulating the current, and fitted with a non-conducting shield, which prevents the radiation of heat, and directs the light to any point desired. The lamp throws such a strong light on the teeth as to render them transparent, when the slightest speck of decay may be at once detected. To develop the full capacity of the lamps requires from 3½ to 4½ volts, that is to say, the current of two to three cells of a Bunsen, or three or four cells of a bichromate battery. A modification of this instrument also serves as a laryngoscope.

EDWARD DAVY AND THE TELEGRAPH.—The following communication as to Mr. Edward Davy's claim to the invention of the electric telegraph has been sent to the Agent-General for

Digitized by Google

Australia by the Premier of the Colony:—"Premier's Office, Melbourne, Sept. 8, 1884.—Sir: I had the honour of receiving, on the 27th August, a deputation from the Royal Society of Victoria, bringing under my notice the claims of Mr. Edward Davy, M.R.C.S., as one of the earliest inventors of the method of using dynamic electricity for telegraphic purposes. From the representations of the gentlemen forming the deputation, it would seem that, though Mr. Davy's claims have for very many years escaped recognition, he is genuinely entitled to the gratitude and consideration of the civilised world. Mr. Davy's claims being thus of world-wide bearing, I at first thought that it might seem presumptuous in me to take the lead in acknowledging them, but it was represented that the fact of Mr. Davy's being domiciled in Victoria gave us a title to move in the matter, and I therefore consented to place the sum of £100 on the estimates for this year, merely as an initiatory step in recognition of his services. The deputation also requested me to assist them in an application to the Imperial Government to get Mr. Davy's name placed on the civil list. I pointed out that an application under this head would come with greater force from scientific bodies, and the deputation accepted my suggestion to move in this respect through the Royal Society of London. I promised, however, to communicate with you, and request you to support in every way in which you can the recognition of Mr. Davy, and this I now beg to do. I enclose for your information a few copies of a printed statement which were left with me by the deputation, and a newspaper cutting, and would refer you for fuller information to articles by Mr. J. J. Fahie and Mr. H. Davy, in *The Electrician*, Vol. XI., 1883. Each of these articles has been issued in the form of a separate pamphlet from the office of *The Electrician*. I feel sure that the matter is one which will gain your interest and attention.—I am, &c., JAS. SERVICE. R. Murray Smith, Esq., Agent-General, London."

REPULSION BETWEEN MAGNETIC LINES OF FORCE.—The following letter, by Mr. R. H. M. Bosanquet, appears in the current number of the *Phil. Mag.*:—The idea of a repulsion between magnetic lines of force was derived by Faraday from the repulsion which exists between two magnetic needles placed "side by side with like poles in the same direction" ("Exp. Res." Vol. III., p. 419). In the deduction of the forces which accompany lines of force, Maxwell reduces them to a tension along the lines of force, combined with a pressure in all directions at right angles to them. Now it is easy to show experimentally, and indeed it is well known, that rings magnetised by means of a continuous coil uniformly wound round them present no external magnetic action, though they may be the seat of closed circuits of magnetic lines of force of very great intensity. It is clear that in this case we may suppose the ring divided into a number of separate rings, each containing lines of force, and that such rings will be wholly without action on one another. If, then, such similar rings be placed parallel and close to each other, they do not repel each other, as they should do if there existed a repulsion between parallel lines of force. Practically, it is impossible to obtain rings so uniformly forged and wound as to be entirely without external magnetic action. This usually manifests itself as a slight polarity, which is easily recognised by a compass-needle, the poles being at the extremities of a diameter. But in my rings this polarity has always been small, even when the induction in the ring was 10,000 or thereabouts. I have suspended two such rings parallel to each other by strings, and made the contacts by the ends of the coils dipping into mercury. But neither by reversing the magnetism of the rings relatively to each other, nor by make or break have I ever been able to cause the smallest movement of the nature of approach or recess of the rings with reference to each other; and this was only to be expected from what is well known. We may notice that, in the illustration of Faraday, the movement of the system of two parallel needles due to their repulsion leads to a redistribution of the lines of force. It appears, therefore, that the repulsion here observed must depend upon this redistribution. To illustrate what is meant, suppose the lines of force to exert their tension like elastic bands on a mechanical system such that, when yielding to the tension takes place, the needles are separated. In this case, whenever the lines of force are prevented from changing their form, the repulsion at right angles to them must disappear; and this appears to be what actually happens.

ADVANTAGES OF COMPOUND DYNAMOS.—With reference to the arguments against compound dynamos, put forth by the *Zeitschrift für Elektrotechnik*, and reproduced in *The Electrician* of 29th November, Herr Uppenborn says that they only have the appearance of being warranted. Thus, it is neither necessary nor possible to attain constancy within 1 per cent. In practice, incandescent lamps constructed for a difference of potential of 100 volts require tensions differing 5 per cent. for being raised to the same temperature. The manufacture of these lamps has not yet attained so high a degree of perfection that such precision may be relied upon. The manufacturer does not employ the same measuring instruments as the engineer charged with the installation, and differences of 4 and 5 per cent. may readily be admitted. Besides, laboratory instruments could not well be put into the hands of a workman. Nor is it true that a compound, for an increase of intensity of 20 per cent. manifests a difference of potential of 3 per cent. A Schuckert machine only shows a variation of 3 per cent., the intensity varying from zero to the maximum. If so satisfactory a result cannot be attained generally, it is at least possible to approach it very nearly. The heating of the machine is not of great importance. Let it be so with a compound, of which the induced has a resistance of 0·31 ohm up to 28 amperes. The resistance of copper increases 0·4 per cent. for every centigrade degree. Let a deviation of temperature be supposed of 20°C., which corresponds with an increased resistance of 8 per cent., or 0·025 ohm. The product of the maximum intensity, 28 amperes by 0·25 ohm, gives 0·7 volt. The inductors of the compounds are, besides, so constructed as to have slight resistance and to heat very little, so that the influence of heating is infinitesimal. A shunt dynamo, *cæteris paribus*, cannot present the same constancy as a compound; and the statement that the difference of potential at the terminals of an Edison dynamo is only 1 per cent. for an increased intensity of 50 per cent. must be taken *cum grano salis*. But supposing this strictly true, it only proves that the dimensions of an Edison machine are quite abnormal. The inductors are excessively large with respect to the induced, especially in the original American type. The machines which gave the diagrams instanced are, on the other hand, almost of the same dimensions, and it is rational to compare them. Now, in this case, the maximum production of the intensity by the difference of potential at the terminals is obtained when R = 26 ohms, and from 30 to 40 ohms the tension increases about 25 per cent. This shows conclusively that it is more advantageous to construct a compound dynamo with an equal quantity of copper, because, under however bad conditions such a machine may be put down, it will never show differences of 20 per cent.

CHARLES FRANCIS BRUSH.

BRUSH, CHARLES FRANCIS, M.E., Ph.D., Electrical Engineer, Cleveland, U.S.A.; born March 17th, 1849, and grew to energetic boyhood. His parents were of old Eastern stock, and they gave their son a goodly bodily and mental heritage for his start in the battle of life. The early days of Mr. Brush were spent on the farm, after which he entered the public schools, his parents taking particular advantage of the excellent school system at Cleveland, where much better opportunities were afforded than nearer his home. While quite young the natural bent of the mind of the future inventor began to manifest itself, and he devised experiments at home and at school that indicated his special taste and aptitude for chemistry, physics, and engineering. In chemistry and natural philosophy, as indeed in his other studies at school, young Brush was very proficient. In 1862, while aged but thirteen years, he made his first experiments with magnets and batteries, and while at the High School, in 1864, he became much interested in the subject of microscopes and telescopes, making a number of them for himself and his companions. He constructed every part of these instruments, even to grinding the lenses. In the same year he devised a plan for turning gas on the street lamps, lighting it, and then turning it off again, by electricity. He also constructed a number of induction coils, and greatly amused himself and his school-mates by experiments with them. Having graduated in a four-years' course at the Cleveland High School in two and a half years, and continuing to show a fondness for physics and other studies of a similar nature, Mr. Brush entered the University of Michigan at Ann Arbor, where he took up a course of study particularly suited to his tastes, and by diligent attention to his tasks he graduated as a Mining Engineer in 1869, being one year in advance of his class. Returning to Cleveland from college, he organised a laboratory and conducted the business of an analytical chemist for about three years, becoming noted for the accuracy of his work and the skill displayed in his manipulations. Immediately after this he engaged in the iron business, in which he remained four years. He was married October 6th, 1875, to Miss Mary E. Morris, of Cleveland. In 1875 the attention of Mr. Brush was especially called to the subject of electric lighting, by experiments tried in Paris and London, and in a conversation with Mr. George W. Stockly, vice-president of the Telegraph Supply Company, the question came up as to whether there was not likely to be a demand for a dynamo machine of an entirely different construction to the Gramme and Siemens machines. Since the times of Volta and Faraday, the problem of using electricity as a cheap and practical illuminator had engaged the attention of the best inventive talent in the world. Although many steps in the right direction were taken, the results that were demanded seemed as far distant as ever, until many of those best posted gave up, and declared success to be impossible. Two things had to be invented. First, a dynamo machine that could generate the proper amount and kind of electrical current for operating a number of lamps in a single circuit. Second, a lamp that could successfully work upon a circuit with a large number of other lamps, so that all would burn uniformly. These two things must be produced, and simplified to such a degree as to make electric light cheaper than large quanties of any other artificial illuminant. As a result of the conversation with Mr. Stockly, it was arranged that Mr. Brush should be afforded any facilities that he might need in the factory of the Company at Cleveland, and if he produced such a machine as was required, the Telegraph Supply Company would undertake its manufacture and introduction. Mr. Brush departed without making any pledges, and constructed his machine in private, at his leisure. It is quite probable that he had already pretty thoroughly worked out the problem in his mind. In less than two months from the time mentioned, Mr. Brush brought his machine to the factory on Champlain-street. It was set up in the shop, connected by wires to an old clockwork electric lamp with carbon points, and by a belt with the main shaft. The brushes were adjusted, the armature revolved, the current of electricity was generated, and the lamp gave forth its brilliant light. It was a complete and gratifying success. Of course many mechanical and a few electrical changes in Brush machines have since been made, and the immense sixty-five light machine of the present, absorbing forty-five horse-power, is not to be compared with the infant of three hundred candle-power. But the invention was substantially completed and embodied in this first essay, and has not been departed from materially since. The machine having been obtained, now for the lamp! Mr. Brush believed that he could make a satisfactory commercial lamp as well as a practical machine, and he proceeded to his second task. This was accomplished within a few weeks. The lamp proved to be an invention almost equal to the machine itself, and as at present constructed it is substantially the same in form and principle as the one first produced. At this time Mr. Brush was less than twenty-eight years of age, but had achieved the beginning of the great success that the world now appreciates and enjoys. The capital now invested in the electrical business as an outcome of the Brush light and its accessories is estimated at over twenty-five million dollars, and the amount is growing larger every day. The most prominent of the inventions of Mr. Brush, manufactured by the Brush Electric Company, are the dynamo electric machines, electric lamps, automatic current governors, carbons, batteries for the storage of electricity, apparatus for electroplating, apparatus for producing power from electricity, &c. Mr. Brush possesses an accurate and available scientific knowledge unsurpassed by that of any inventor. He is a self-taught mechanic, and is able to do shop work equal to the best trained men. He is intensely practical, never sanguine, with no disposition to over estimate his work, and is an excellent business man in the management of his own affairs. If an exceedingly delicate or accurate piece of work is to be done for the first time, he will probably do it with his own hands in his laboratory. He usually spends from 10 o'clock a.m. to five p.m. in his sanctum, busily engaged in one of his numerous undertakings or investigations. With the whole resources of a large manufacturing establishment, filled with the most costly and convenient machinery at his command, he probably has the best facilities for experiment and demonstration of any living inventor in the electrical field. In 1869 the University of Michigan conferred upon him the degree of M.E. In 1880 the Western Reserve University invested him with the degree of Ph.D.; and in 1881, in connection with the Electrical Exposition held in Paris in that year, the French Government, in honour of his distinguished inventions, services, and contributions to the world of science, decorated him Chevalier of the Legion of Honour. At the Michigan University he was a member of that famous college society, Δ K. E.

OLD CABLE STORIES RETOLD.—VII.

BY F. C. WEBB.

(CONTINUED FROM PAGE 511, VOL. XIII.)

THE RED SEA AND INDIA CABLE OF 1859—1860.

The British Government never took any very deep interest in Atlantic cables, but they were very anxious, even as early as 1858, for telegraphic communication with India, and in 1859 a company had been formed for laying cables from Suez to India, having a guarantee of 4 per cent. for fifty years, whether the cable worked or not, for no money could be raised then on a guarantee conditional on the cable working. The cable was to start from Suez, and touch at Cosipe, Suakim, Aden, Kooria-Mooria Islands and Muscat, ending at Kurrachee.

Messrs. Newall and Co. had the contract for making and laying the cables, and by the middle of 1859 the sections from Suez to Aden had been laid from the steamers "Imperidor" and "Imperatrix."

Towards the latter part of 1859 I was engaged by the Red Sea Telegraph Company to proceed to India and test the sections about to be laid from Aden to Kurrachee, and on the 9th of November I started for India *viâ* Paris. On the 10th I was assisted in getting my instruments, &c., passed through the Custom House at Paris by my old friend Mr. Spiers (father of the Mr. Spiers of refreshment room improvement celebrity). Mr. Spiers always knew the best piece to see at the theatres, and where best to dine. That day we dined together at Vefours. He was a Director of the Submarine Telegraph Company, and so knew something of submarine cables, and as he was agent to the London General Steam Navigation Company he was well known by the Custom House authorities. He gave me letters to friends at Marseilles to facilitate the clearance of my instruments there. He was a genial, kind-hearted man and good man of business, and I never used to pass through Paris on any of my trips without calling on him, but can do so no more, as he died some three years ago. I arrived at Marseilles on the 11th. The English mail "Vectis" was quite full, so I had to take passage for Alexandria in the Messagerie Imperiale steamer "Danube," which started on the 13th. During my stay at the Hotel des Ambassadeurs I made acquaintance with Mr. Stanley, the Consul at Jeddah, in the Red Sea, and soon found he was another of my old Brussels schoolfellows. Jeddah had some months before been the scene of a massacre; the English Consul had been killed, and H.M.S. "Cyclops" had been ordered to bombard the town. Then this order was countermanded, but the ship carrying the message of countermand in some way passed the "Cyclops" in the night, and went on past Jeddah, and the "Cyclops" arrived and bombarded, but did it in a merciful way, for after the first few shots they slung a 68-pounder and fired right over the town to show what they could do if they liked. The "Cyclops" had been taking soundings in the Red Sea, &c., for the cable, and was one of the ships that I was afterwards on board for a month.

We arrived at Alexandria on the 20th. Mr. Brunton (formerly under Mr. Statham at the Gutta Percha Works, Wharf-road) was the general manager of the line, and was at Alexandria, and I reported myself to him. Mr. (now Captain) Mayes, R.N., was also there. He had been master of the "Cyclops," but was at the time I allude to in the service of the Red Sea Telegraph Company, and was to have the command of the repairing ship. This ship had not arrived out up to the time I left the whole work, and I am not sure that she ever came out at all. I don't know what her name was or who fitted her up, or when she was bought. She seemed to me a kind of "Mrs. Harris," although, I suppose, she must have had some sort of existence. Mr. Gisborne (a relative of Mr. Lionel Gisborne, the engineer) was the superintendent at Alexandria, and I lunched at his house on the 22nd. He had a beautiful little tame gazelle that strolled about in the dining room.

On the 23rd I went on to Cairo. For some distance from Alexandria one of the land lines had L. Clark's double cup insulators. I put up, of course, at Shepherd's. On the 24th I did the Pyramids with two American gentlemen named Fetridge and Millar, who had been fellow passengers with me from Malta. I could have got up to the top of Cheops without any great stress of muscle or breath, but that the Arabs who drag and pull and push at you got singing such ridiculous bits of broken English, ending each stanza with "Oh! Englishman very good man. He give backsheesh when he get to the top!" that I got into a fit of laughter, and the more I laughed the faster they pulled, so that when I did get to the top I had no breath left at all, and could only lie down on my back and pant for a good ten minutes. A lady who was at the top said that all the others that came up were red in the face, whereas I was deadly pale. The fact was, I believe a little more and the Arabs would have been dragging up a smiling corpse. I made a sketch of the other pyramid from the top of Cheops, and have it now. After lunch we went inside the king and queen's chambers, and then looked at sphinx, and I took a sketch of that. Then back to Shepherd's by 7 p.m. to dinner. When chatting with my two American friends one said, in the course of a political question, "Why on earth don't you Britishers take Egypt and have done with it?" I thought it a very good idea, though I don't know that it was a very novel one, and have no doubt if we had taken it in '59 or '60 the country would have been by this time in a respectable and settled state.

On the 25th I did the mosque, &c. In the evening the passengers from Bombay arrived, and I suppose it would be difficult to find any hotel where passengers arrive in such great crowds all at once as at Shepherd's. It was a very curious scene of confusion, bustle, and jabber, with a band playing outside to add to the general noise. It may be more so now, or less if there are more hotels, that I cannot say, but at that time it was one of the most curious sights I had ever seen.

I started for Suez on the 26th, at 8 a.m., by a train that was not taking the eastward general flood of passengers through. There was only one second class carriage, and no first class. My two American friends, two French ditto, Mr. Stanley, and Mr. Sheath (formerly clerk in charge at the Hague) were with me. A water train broke down in front of us when we were about half way to Suez, and stopped us for an hour. There were four railway wires, with Edwin Clark's zinc cap insulators. The Red Sea telegraph line had Siemens and Halske insulators, and this line did not keep to the railway, but made short cuts in different places. We got on to a station in the desert, and had some lunch at this station. It was only a station; there were no houses or huts. I found there a telegraph clerk who I had known in the Electric Telegraph Company. It was quite delightful to find a friend in such a lonely place. We got to Suez about 2 p.m., and I saw my friend Mr. Stanley start off for Jeddah in an Egyptian steamer.

The hotel at Suez was a very different place to what I expect they have there now, and there were very few people in it. In the evening we were smoking a cigar in the proprietor's room. There was an English baronet, who was on his way to New Zealand, and he had about a dozen partridges that he was taking out to his lands there. He had started from England with seventeen more, all of which had died up to that time. The remainder were therefore getting very precious, considering the percentage that had died and the distance still to be traversed to New Zealand. The birds were in cases with a kind of cage-front made of battens, and had been brought up into this room and placed with the battens against the wall. Now the master of the hotel had a tame mongoose. The little creature had been running about the table and amusing us with his pranks. He had disappeared, and we were chatting, when suddenly the baronet jumped to his feet, rushed like a maniac at his cages, tore off some battens, and the next instant the mongoose was high in the air describing a trajectory to the other end of the room. But five more of the partridges had gone the way of their own majority. The little sly wretch of a mongoose had got in between the wall and the cage and then between the battens, and would have slaughtered the whole lot had not the owner of the partridges heard a faint cry from the fifth. I always wondered, firstly, how it was the baronet did not get bitten, for he had seized the mongoose regardless of consequences;

Digitized by Google

secondly, how it was the mongoose was not killed when he struck earth (or floor); and lastly, I always wondered whether the baronet ever got a single partridge to New Zealand. I hope he got a brace there, for he was a very nice fellow, and I had travelled with him from Marseilles; but his case was not hopeful at Suez. In fact, from the above particulars I should estimate, as an engineer, that to get a couple of brace of partridges to New Zealand from England you ought to start with at least a thousand.

I am afraid this is scarcely about cables, but you must recollect, Mr. Editor, that I am, or was, waiting at Suez for a ship to take me on to Bombay. On the 27th I went with my American friends, Fetridge and Millar, in a boat to Moses's Well, about ten miles down the Red Sea, on the Arabian coast. It was a Sunday morning, and one of the Americans was of a rather serious turn of mind, and wore spectacles, and he took his Bible with him, and as we sailed along endeavoured to glean from the Arab boatmen something about any traditions that might exist as to where the Israelites crossed the Red Sea. He had his Bible open, and was constantly asking questions of the boatmen, who gave answers which, as far as we could make out, gave us no information, indeed continued to puzzle us more and more. At last the less serious of my two friends said, "Now, let me try to get at it;" then to the Arabs, "Now, look here, *who was it* that were after the *Israelites?*" There was instantly a chorus of "*Rascally Bedouins, sar!*" They thought we were talking of a murder that had taken place three weeks ago, when some poor traveller was murdered by some Bedouin Arabs. The serious American shut up his Bible, and his friend indulged in a tremendous fit of laughter, and afterwards wrote in the visitors' book at Suez Hotel, "Discovered that the Israelites were not pursued by the Egyptians, but by rascally Bedouins," and signed it "A Seeker after Knowledge." There was not much to see at the wells. There are fifteen wells with the crazy picturesque water wheels carrying an endless rope with small earthenware pots to bring up the water. There were two or three huts there, but one of these we could not go into, because some ladies from a harem were there. A jolly old Arab lent us two camels to ride back to the boat, and the jovial American and I rode on one, and we were greatly amused at the peculiar motion and the groans the animal uttered when made to lie down by the Arab in charge.

ELECTRIC LIGHTING IN AMERICA.*

BY W. H. PREECE, F.R.S.

Electric lighting is flourishing in America much more than at home. There are, probably, 90,000 arc lamps alight every night in the States, and there are many central stations working regularly, both with arc and with glow lamps. I know nothing more dismal than to be transplanted from the brilliantly illuminated avenues of New York to the dull and dark streets of London. This has happened to me very recently. On the evening of October 21st, I drove from the Windsor Hotel, New York, to the Cunard Wharf, a distance of about four miles, through streets entirely lighted by electricity. On October 30, I drove from Euston to Waterloo without seeing a single electric light, having been on the ocean during the intervening period. I visited Montreal, Philadelphia, Buffalo, Cleveland, Chicago, St. Louis, Indianapolis, Boston, and New York; finding in each city the principal streets and warehouses, as well as stores and places of public resort, lighted by arc lamps. After so much brilliance in these cities, the return to dull gas has a most depressing influence. It is with arc lighting that the greatest advances have been made in the States. One manufacturer alone told me that he was turning out 800,000 carbons for arc lamps per month, and another said that his output of plant was fifty arc lamps and three dynamos per day; and while I was present at a third factory, an order was received for an electric lighting plant of 330 arc lamps requiring fourteen 24-light dynamo machines, intended for an installation to light up a driving park in the environs of Chicago. As an instance of the growth of electric lighting, I may mention that in Chicago the number of arc lamps installed has doubled, viz., from 1,000 to 2,000, during the past twelve months, and the number increases daily. More than one electric light company pays dividends to its shareholders, and all of the manufacturers as well as the lighting companies seem to be full of work. The principal systems in use are, for arc lamps—the Brush, the Weston, the Thomson-Houston; but there are other arc systems, not so well known on this side of the Atlantic, such as the Hochhausen, the Van de Poel, the Western Electric, the Fuller, the Sperry, &c. For glow lamps—the Edison, and the Weston. I will describe briefly the systems I saw in use, dividing them into (1) arc systems and (2) incandescent systems.

* Paper read at Society of Arts on Wednesday, December 3.

I.—Arc Systems.

The Brush System is so well known that it scarcely needs any reference, excepting to point out that a very considerable improvement has recently been made in the dynamo machine, which has very largely increased its capacity and output. The new Brush armature consists of layers of thin sheet iron, insulated from each other. By this arrangement induced currents—improperly called "Foucault" currents, for they were fully described by Joule as far back as 1843—which produce heat, and thereby diminish the efficiency of the machine, are prevented from being formed; and, further, should heat arise through excess of current, thorough ventilation is effected to carry it away by convection. Brush dynamos, which previously, with the old armature, lighted sixteen and forty lamps respectively, now, with the new armature, excite thirty lamps and sixty-five lamps; so that it will be seen that the improvement is very considerable.

The Weston System.—This system, looked at from a mechanical point of view, strikes one as being probably the best in use in the States. The machine itself is of the Siemens form, but the armature is made up of discs stamped out of thin sheet iron, and separated from each other by washers. By this method, first suggested by Joule in 1843, those disturbing induced currents are entirely checked, and thereby the undue heating of the armature prevented. Mr. Weston appears to have been the first to have practically carried out this very sensible idea, and it is being rapidly adopted by other makers of dynamo machines. I have mentioned that Mr. Brush has followed out the same idea. The commutator in the Weston machine differs from most American commutators, in that it has no less than 140 segments, which tend to prevent "sparking," a very disturbing element in the action of dynamos. In fact, the absence of sparks is one of the striking features of this machine. There are standard Weston machines for working arc lamps, and also for working glow lamps. Both kinds are shunt wound, the former being supplied with a most sensitive and extremely ingenious regulator, which adjusts the strength of the shunt current or field magnets, so as to maintain the current in the main line constant. The 200-lighter Weston dynamo for glow lamps is peculiar in the extreme lowness of the resistance of the armature, which is only ·0011 ohm, while the resistance of the shunt is 24 ohms, thus having a ratio between them of 1 to 2,182. The result of this lowness of resistance is such that the resistance of the armature may be neglected, and therefore the dynamo becomes self-regulating. I saw 199 lamps out of 200 suddenly extinguished, without producing any apparent change in the incandescence of the one glow lamp left. The electromotive force of this machine is seventy volts when rotated at 1,000 revolutions per minute. The arc lamps of the Weston type do not call for special notice, excepting to record the remarkable steadiness of their burning. They are fed on the differential principle, but they owe their steadiness and good working to the perfection of workmanship and the mechanical finish of their parts. The beautiful suspension bridge at Brooklyn is lighted entirely by eighty-two Weston lamps. This is done by the bridge trustees themselves, and the view of this bridge at night from Staten Island and from the magnificent harbour of New York is one of the prettiest optical effects I have ever seen. New York harbour will soon be so brilliantly illuminated by electric lights that one of the enterprising ferry companies contemplates having nightly excursions, which it is intended to advertise as the "Theatre of New York Harbour by Electric Light; price of admission 10 cents." Local companies using the Weston arc system are successfully operating central stations, supplying a large number of lights for rental at Boston; Springfield, Manchester; Providence, Rhode Island; Newport, Rhode Island; New York City, Rochester; Elmira and Glen Falls, New York; Newark, Cape May; Atlantic City, &c.

The Thomson-Houston System.—This system is unknown at present in England. It contains some considerable and ingenious novelties. The armature is spherical, and is almost entirely encased by the field-magnets; the magnetic field thereby becomes enclosed, and is very intense. The dynamo is series wound. The commutator consists of only three sections, and there are only two pairs of brushes. It has an automatic governor, which adjusts the lead of the brushes to positions of varying electromotive force as the work itself varies, so that, however much the number of lamps may change, the current remains steady. It has a peculiar air-blast device, to prevent undue sparking at the brushes; strong currents or puffs of air prevent the formation of those lines of minute conducting particles which bridge across the air spaces at the commutator, and whose presence forms one cause of so-called "flashing," and they blow out the sparks which would form at the brushes. The arrangement also admits of the free oiling of the commutator, a point of very considerable importance, at a place where there is so much wear, and a peculiarity of this dynamo. The ordinary size Thomson-Houston dynamo lights up twenty-five arc lamps, and it has 225lb. of copper on the armature, and 700lb. on the field-magnet. When rotated at the ordinary speed of about 900 revolutions per minute, it acquires an electromotive force of 1,200 volts, and generates a current of 9·8 amperes in the lamp current. The lamps have an average resistance of 4·5 ohms, and the electromotive force that each lamp takes is 45 volts. A 25-lamp circuit absorbs 23·25 horse-power. The commercial efficiency of this machine is therefore 80 per cent. Frequently as many as seven of these dynamos are joined up in series. An interesting example of lighting is that of a new swing bridge crossing the river at Rush, near Chicago, which is moved with promptitude and lighted with brilliance by steam engines fixed in the centre of the bridge. All connection with the shore is cut off, but the whole thing works with great steadiness, although a heavy traffic, four abreast, is maintained all day long.

The Hochhausen System.—This is slightly known in England, from its employment in the recent International Health Exhibition to light up the tall mast in the centre of the gardens, but it has scarcely received the

Digitized by Google

attention that it merits. It is doing a large business, but I did not visit any places worked by it.

Central Stations.—I visited the central station of the Thomson-Houston Company at Montreal. It was opened on the 14th March last, and on September 3rd, when I was there, there were 164 arc lamps alight in the public streets and shops of the town. The wires through the town were all of copper, principally No. 6 gauge, covered with cotton and asbestos, and were in all cases carried through the streets on unsightly posts. The rate charged is 50 cents per lamp per night, the lamps being lighted from dark to midnight; this means over £35 per lamp per annum. I visited other central stations worked on this system, and I learned that it was decided to light up the public streets of Ottawa entirely by the Thomson-Houston system. In that case the power will be obtained from the celebrated Chandére Falls, that add so much picturesqueness to the position of Ottawa and wealth of its inhabitants, for it is the great source of power used to carry on the timber trade of the place. Another central station that I inspected was that of the Brush system, at Philadelphia; there 1,200 horse-power was employed in supplying electricity for nearly 1,000 lamps. As in Montreal, open wires are used, supplying 25 circuits, some of which are four miles long. The charge for each lamp is 25 dollars per month, which is equal to £60 per lamp per annum. The Brush people have also two central stations at Boston, lighting up 816 arc lamps; in fact few towns of any consequence in the States do not possess central stations worked by the Brush Company. There are, probably, 25,000 Brush arc lamps in use in the States. At Chicago there are now over 2,000 arc lamps going, and they are increasing in number every day. The Lincoln Park has all its drives lighted by arc lamps, with very great effect, especially on the unique drive skirting the shore of Lake Michigan. There are several central stations belonging to various companies in Chicago, viz., the Western Electric, the Van de Poel, the Fuller, and the Sperry Company; while the Hochhausen system is about to be started with a central station for several hundred lamps. I did not observe any particular novelty in the form of lamps used, and the impression I gained was that there were some European lamps that far surpassed the American ones in steadiness and efficacy.

Street Lighting.—I did not see in the States one single instance of street lighting by glow lamps. In every case arc lamps were used for this purpose, and they were usually fixed on much taller posts than we are accustomed to see in England, arranged in zigzag fashion along the streets, at a distance from each other of about fifty yards. Although the effect of this street lighting by arc lamps was brilliant, it was by no means perfect, and no effort seems to have been made to distribute the light uniformly, as has been done in England by Mr. Trotter; and, in fact, the question does not seem to have been attacked at all from a scientific point of view; the commercial spirit alone appears to have been exercised in developing this enterprise. An interesting experiment has been tried in Cleveland, where eight Brush lamps are fixed upon the tops of four iron masts, each about 250ft. high, fixed in prominent positions in the city. These masts were made of riveted boiler plate. They were erected *in situ*, and raised by jacks as they were made. The diameter is 8in. at the top and 3ft. at the bottom; they cost £800 each. I am bound to say that, to me, the effect was very poor; the streets were illuminated only by a light equal to a very pale moonlight, concentrated, as it were, at one end only. There are 300 other arc lamps in Cleveland. At St. Louis, the Court House in the centre of the town was surrounded by permanent arc lamps, but except for illuminating the dome of the Court House itself, the effect upon the contiguous streets was poor. Here one of the streets was lighted by two arc lamps on each pole on one side of the street, and the effect was certainly indifferent, and gave one the idea of a great waste of light. Washington has been experimentally illuminated by the Brush-Swan Electric Light Company, by very large arc lamps, 4,000 candle-power each, fitted with large conical reflectors, throwing a great body of light down the streets to be illuminated. The various avenues radiating from the Capitol are thus lighted, and a circle of 14 lights, without reflectors, surrounds the top of the Capitol, the effect of which, I am told, is certainly very fine. I have since learned, however, that, after an experimental run of 45 days of these lights, the commissioners empowered to decide upon the success of the experiment have given their veto against its continuance. It is, perhaps, interesting to point out that the price paid in New York is 70 cents per night, or £50 per annum for each arc lamp; but a fine is inflicted on the lighting company of 1·40 dols. for each time that each lamp is reported to have been out; a healthy check is thus kept upon the good working of the system.

(TO BE CONTINUED.)

FATAL ACCIDENT FROM AN ARC LAMP.

At the inquest held on the unfortunate lad, William Moore, aged 19, who was killed by an electric shock through touching a Brush lamp at Bolckow, Vaughan, and Co.'s steelworks, Eston, Middlesbro', on 25th November, the following facts were elicited:—

William Broughton, an engineman, deposed that early on Tuesday morning deceased, who was employed at the works as oiler and cleaner, called his attention to a hot bearing, and, while he went to look at it, he heard him call out "Oh, Bill!" On looking round, he saw a number of men, who had rushed to the spot, picking up the deceased, who seemed quite dead. The electric wires were about 3ft. over the men's heads; and it was no part of the business of either witness or deceased to interfere in any way with the light. If it should go out they were instructed to send to the electrician's office, and a man would be sent to re-start it. Notices were posted in all available places in the works warning men not to touch the lamps or the wires. When the light goes down, a tap or two with a stick would bring it up again.

George William Parker, engineman, stated that he saw the deceased on the engine house stage. When the electric lamps went out, deceased picked up a piece of stick and tried to light the lamp. Deceased seemed to place his hand on one of the rods, when a connection seemed to be made. Witness was running towards the electric engine to get it stopped when deceased fell. He did not see deceased take hold of any other part of the lamp. Witness had seen the notices warning men of the danger of touching the wire.

Walter Blower, electrician for Messrs. Bolckow, Vaughan, and Co., said that the following notice was posted all over the works:—"Danger. We caution the workmen not to interfere with or touch the wires, lamps, or connections of any kind belonging to the electric lighting. By order." He knew the deceased, but had not seen him interfere with any wire. He was constantly cautioning the men, and on Thursday last, while in the engine house, he cautioned the deceased and the witnesses. By taking hold of the bar mentioned by the last witness, one came in contact with the circuit, and the effect of that was seen by the death of the deceased. Witness saw deceased after the accident, and noticed that his right hand was scorched, which proved that he had made the circuit.

Dr. John Glen said he had made a post mortem examination of the body of deceased. There were no external marks of violence, only slight abrasions of the skin. The palm of the right hand was scorched, as though deceased had taken hold of a red hot bar. Upon making an examination, he found all the internal organs healthy, but highly congested; the brain was also perfectly healthy. From that examination he came to the conclusion that the cause of death was a violent shock, owing to coming in contact with electricity. The effect was very similar to lightning; but in this case he should say that there must have been actual contact.

The jury returned a verdict that deceased had died from a shock received through his having taken hold of the wire attached to the electric light.

In this case, both lamps and wires are evidently placed out of the ordinary reach of the workmen, and abundant warning given not to touch them. The deceased met with his death through interfering with what not only did not concern him, but what he had been warned in every way not to meddle with.

PARLIAMENTARY NOTICES FOR NEXT SESSION.

The Corporation of Ramsgate, in the Bill which they have notified their intention of introducing in the next Session of Parliament, ask for powers authorising them to provide and maintain for their establishments or offices telegraphic or telephonic communication between any parts of the borough, and for such purposes to incorporate, extend, or apply all or some of the provisions of the Telegraph Act, 1863, or any other Act or Act amending the same.

The Corporation of Hastings will ask for powers in the Act for which they intend to apply to provide for the regulation, alteration, and removal of pipes, tubes, wires, and other apparatus connected with telegraphic, pneumatic, telephonic, electric, and other purposes within the borough, and to establish communication by any such means between the Town Hall and the several offices of the Corporation.

Authority will be asked for in the Act which the Corporation of Wigan will apply for empowering them to prohibit or regulate by license or otherwise "the placing or maintaining of wires, conductors, cables, tubes, or other projections, works, or things, over, above, along, across, or beneath streets or other public places within the borough."

In the Bill which the Corporation of Bradford notify their intention of applying for clauses will be inserted empowering them to erect and maintain electric lines and works, and to supply electricity within the borough.

By the Act which will be applied for to extend the limits of the Local District Board, or (as the case may be) the Municipal Borough of Mossley, provisions will be made "for licensing, regulating, and otherwise in relation to the fixing, placing, or attaching of telegraphic wires, tubes, and apparatus."

The Corportion of Lincoln intend asking for leave to introduce a Bill authorising them to acquire the undertaking of the Lincoln Gaslight and Coke Company, and to empower them "and (if deemed expedient) to the exclusion of any other person or company (*a*) to produce, store, distribute, and supply, for public or private purposes, within the gas supply district of the Corporation, light, heat, or motive power by means of electricity or any light (other than gas) produced by artificial means or power, and for those purposes, or any of them, (*b*) to exercise all or any of the existing powers of the Company or the Corporation relative to lighting by gas, or oil, or such other powers, rights, and privileges as may be conferred by the Bill," &c.

The Chelsea Electricity Supply Company (Limited) notify their intention of applying to the Board of Trade, on or before the 20th inst., under the provision of the Electric Lighting Act, 1882, for a provisonal order empowering them to produce, store, and supply electricity within the parish of Chelsea. For these purposes authority will be asked for "to enter upon, break up, and interfere with," all streets, railways, tramways, gas and water pipes, telegraph and other wires and pipes, &c., and to enable the Company to manufacture, hire, sell, and let all necessary machines, plant, &c., required for the purposes of the order; to acquire land, levy rates, &c.

ANSWER TO CORRESPONDENT.

J. H. D. (Moscow).—*Your letter has been handed to a gentleman who will write you fully on the subject.*

THE JOURNAL OF PATENTED INVENTIONS.

We have looked forward with some impatience to the publication of the illustrated journal which, under the provisions of the Patent Law Amendment Act, was to be issued from the Patent Office for the information of the patent-loving public; and we have at length received the first number. Upon a very cursory examination of its contents we find many things to speak about; but, first of all, we desire to give it a welcome none the less hearty because of the faults we have to find with it, and the delay which has occurred in its publication. It bears date November 28th, and brings its information down only to February 11th; but as it is to be issued weekly the lost time, perhaps, may be soon made up. When we ourselves, in common with other technical journals, essayed to summarise and illustrate inventions even of a limited and special kind we found it impossible to keep up the pace; and for this and other reasons the attempts have generally been abandoned. The official journal is now to assume the task on a broader basis; and in the hope that it may be performed in a thoroughly satisfactory manner we take leave to offer some friendly criticisms on the first number.

At the outset we must protest against the price of the *Journal*. A shilling is, from every point of view, twice as much as it is worth, and is, we apprehend, prohibitive; whereas at fourpence or sixpence it might stand a chance of paying for its production. Subscribers at a guinea a year might be reckoned by hundreds, where a subscription of two and a half guineas will be counted by tens. In this connection we would suggest a small addition to the outlay upon the Index. It seems to have occurred to the compiler at the last moment that an index is demanded nowadays with any book pretending to completeness; and he has given us one—one that is unique of its kind. It is an index, not to the subjects of the inventions, as would naturally be looked for, but to the numbers borne by the patents relating to them. Thus we are informed that patent No. 1,692 will be found at page 19, a piece of help which nobody needs, seeing that the numbers are arranged consecutively. A blunder of this kind is characteristic of the official mind. In the routine atmosphere of the Patent Office an invention appears to be like a convict in penal servitude, it becomes a mere number, a thing to be traced, but not to be recognised. We would say to the ingenious compiler, A fig for your numbers; let us know what they stand for!

Turning to the contents of the journal, there is evidence of the same unpractical mind at work. Prominence is here again given, quite unnecessarily we think, to the number. It is of no more importance than the date, which ought certainly to come last, whereas it immediately follows the initial number. The title of the patent is in prominent type, which is good; but why is it relegated to a third place? It ought to be most prominent of all, and as far as type can make it, no fault can be found on this score. But the effect of giving it a third place and generally to split it up into two lines is not only "spotty" from a printer's point of view, but confusing to the reader—or rather searcher, for we are dealing with what is essentially a book of reference, where every trifling detail should conduce to the easy finding of what is being sought. Taking examples at random, what can be more vexatious than the splitting up of titles in this manner:— **Regulating flow; Packings for; Pruning or bill**—all of which occur on page 25, to say nothing of **Window venti-**, the context of which may perhaps be guessed at without diving into the next line. The titles are uniformly short, and they ought to appropriate the first line as a distinct heading. **Automatic spe-** (page 22), **Balanced ther-** (page 14), are inexcusable divisions; and **Adjustable chin, Preserving, &c.,** on page 6, are absurd. Speculum and thermometers, we may explain, are the words needlessly severed; and the adjustable chin has nothing to do with anatomy, but relates to a chin-holder for violins; whilst the fourth example refers, not to preserving of either jams or *etceteras*, as a first glance might lead us to suppose, but to the preserving bottoms of ships. A first glance ought to suffice; the compiler of the *Patent Journal* compels us in most instances to take two.

With the wood cuts which profusely illustrate the *Journal* we have no fault to find on the score of workmanship. As a rule, they are admirably done, and like the letterpress, are excellently printed. But the engravings are not all of equal merit, and one or two of them are a disfigurement. This much for the engraver. But who is responsible for the respective space assigned to each figure? Not the engraver, we feel certain, for he would never sacrifice clearness to economy in the way it has been sacrificed over and over again in these pages. For the original drawing the office is, no doubt, indebted to the patentee; but we may be sure he made his meaning clear, if he had any. To look at some of these diminished reproductions one would suppose he had none. At least twenty per cent. of them are utterly unintelligible; and, for all the light they throw upon the text, the money spent

Digitized by Google

on engraving them is clean wasted. No discrimination appears to have been exercised in this particular. Take for example, again at random, page 3. There is the outline of a Shirt, the essential point about which might be indicated within the area of a lady's finger nail; yet it occupies space half as big again as that allowed to a Burglar Alarm, with complicated details which nobody can follow on such a reduced scale. A Tobacco Pouch on page 4 is favoured like the Shirt, and so is a certain, or rather uncertain, Egg-cup which we decline to advertise more particularly; whilst a Weighing Machine and a Padlock, on page 15, are obscured by unnecessary detail, or detail too minutely traced to be followed. On the same page is a picture of a bookbinding press, the like of which we hope never to see repeated. It is a picture, and that is all.

We have left ourselves no space to speak of the inventions which these pages are intended to usefully make known to the world. As a first instalment of the new patent law they do not strike us as particularly startling in anything but their numbers, which on the 11th February had reached 3,094. This at least represents the number of applications during the first six weeks of the present year. As to the amount of inventiveness disclosed we cannot at present form any positive opinion; but we are certain that we shaved our editorial chin —not adjustable—fifteen years ago with the identical razor depicted on page 15 as a new invention; and it cuts our corns fairly well even now.

CORRESPONDENCE.

THE SILENT ELECTRIC ARC.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The very interesting paper on the silent electric arc in your last impression needs, I venture to say, some explanation, which the author will perhaps give.

I have made hundreds of experiments in arc lighting, and I can corroborate much that Mr. White says, but not all. I find, for example, that too many amperes will cause carbons to hiss, no matter what the arc; also that only good carbons are silent, no matter what the arc. I may perhaps add that the author has not explained why an arc is silent.

But the point on which I want information is this: All my experience with self-exciting Gramme machines is that as the length of the one increases so does the E.M.F., while the number of amperes decreases. This is not the result got at by Mr. White. For example take Table I.; we have amperes 10·59, volts 39·94, amperes 13·59, volts 40·61, and so on. Furthermore, it appears that as the distance between the carbons is augmented the resistance diminishes; my experience is that it augments. If not, will Mr. White kindly explain to me why it is that, as the carbons burn further apart, the number of amperes steadily diminishes, and that just the same result can be brought about by putting a resistance into the circuit. One of the lamps with which I have experimented depends for its action entirely on the diminution in the number of amperes as the carbons burn away, and it works perfectly; but I need not argue the point, for Mr. White's own figures prove the diminution, only he leaves the volts unaltered.

Not to take up more of your valuable space, I venture to ask why it is that doubling the distance between a pair of carbons will reduce the resistance of the coil from 6·23 ohms to 2·07 ohms? In the first case, too, we have 5·94 ampere and 37 volts. Now $5{\cdot}94 \times 37 = 219{\cdot}78$ watts, the separation being 1¼mm, or say $\frac{1}{20}$th of an inch. In the second case we have 20·3 ampere and 42·15 volts and $20{\cdot}3 \times 42{\cdot}15 = 855{\cdot}64$ watts. This is an exceedingly puzzling statement as it stands. The separation of the carbons was 2·77mm., or say ·108 inch in the last case. Are we to understand that this great increase in electrial energy was due to the burning further apart of the carbons—that, in short, it resulted from the descent of the resistance from 6·23 ohms to 2·07 ohms?

My own experience has always been that the shorter the arc the greater the load thrown on the engine, for obvious reasons. In the case cited, however, it would seem that the longer the arc the greater the work thrown on the engine.

I never yet succeeded in getting a silent arc with a separation of less than 0·1in., and some of my best results have been with an arc of $\frac{3}{16}$in., about 42 volts, and 11 to 12 amperes for 11mm. carbons.

Great thanks are due to Mr. White for his very original work in a new field of research. I am sure that if he will favour your readers with the explanation I ask for others will be grateful as well as—Yours, &c.,

Dec. 2, 1884. A PRACTICAL ARC.

SELF-REGULATING MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue I see that my friend, Mr. William Macgregor, has been taking up the cudgels on my behalf in the matter of compound-wound machines. In the main his statements are correct (except some amusing vagaries of the printer's devil as to proper names). Your editorial note, however, contains news to me, that there is claimed for Mr. Edison compound winding as his prior invention. As a fact, though, I do not think my claim to be the first to apply double winding *to the definite purpose of supplying the current at a practically constant electromotive force* has been successfully set aside, even by Mr. Edison's claim. For I pointed out in my book on electric lighting, published in 1879 (and written in 1878), in describing Mr. Brush's "teaser" arrangement, that there were other useful applications than to the purposes of plating; and I had in mind in writing that sentence (p. 83) the double winding I afterwards developed. Any claim of Mr. Edison's was quite unknown, it would seem, to the U.S. Patent Office Examiners in 1881, as no reference was made thereto by them in their examination of the claims for my patents, although many instances of *merely* double winding were adduced by them, some of these being now nearly thirty years old. However, as I say, I still believe I have been the first to practically carry out double winding with the definite law and purpose of supplying parallel circuits at a constant electromotive force. But I have no desire to be too persistent in what has now chiefly a bibliographic value, for compound wound machines have, as to true economy in electric lighting, only a limited use. It is amply proved by the performance of Mr. Weston's recently introduced dynamos that, given a sufficiently powerful field and a very low resistance, armature simple shunt-wound machines are self-regulating. The ends to be attained satisfactorily by compound machines are supplying current to a small number of lights in parallel circuit, where the resistance of the armature as determined by the dimensions of the machine must be comparatively high, or to the supply of several branch circuits in the electrical transmission of power to a considerable distance from one generator. As to the supplying of current for incandescent lighting with true economy as a whole system, I have had a painful experience that it is not to be done with any method employing the power obtained from engines directly; because the variation in the speed of the engine is in itself too great for long life of the delicate filaments of the lamps. In the case of the very admirable Edison installation in New York, we are told that the lamps average only 400 hours of lighting, although here probably the greatest care practicable has been taken to ensure steady running and a low incandescence of the lamps. It is a matter of common knowledge to electricians to suppose that lamps run from a machine direct blacken or break much sooner than those in circuits in which accumulators are interposed. In my professional practice I have during the last two years been in charge as consulting engineer of a large installation, partly run from dynamos with accumulators, and parly from dynamos directly, and both parts from the same source, a very excellent steam engine. In the

Digitized by Google

one case no lamps have been broken, except by accident; in the other renewals of lamps are the rule. It is for these reasons as to the fallibility of any mode of winding that I hope you will absolve me from undue pertinacity in my claim as to compound winding.

Will you permit me to add a few words in conclusion? I do not think compound-wound machines have been generally constructed on the best principle. It seems to have been overlooked, that with both shunt and main coils wound on the same limb of the electro-magnet, an excess of iron in the electro-magnet core is in practice necessary to secure proper regulation [flatness of curve in diagram]. In the method of winding on separate limbs proposed by myself this excess of iron is avoided or is afforded by the arrangement of the mass of iron of the main magnet core. Further, in the "tripolar" electro-magnets, common to the Gramme and other machines, when the separate cores are each devoted to its circuit [and consequent as well upon what has just been stated] there can be used comparatively much lighter electro-magnets with the same armature, in small machines, without danger of sparking; because, instead of need of shifting the brushes around the commutator, *the point of greatest concentration of magnetic field in the pole pieces is made to shift relatively to the armature* by the increase of magnetism of the main circuit core. Another advantage of the separate system is that fewer turns of main-magnet wire, and consequently less resistance, are needed in the main circuit. Whilst only few lamps are alight, the shunt magnets are partly muffled by the inert mass of the main magnet cores; when more lights are switched in and more current passes around the main coils, these cores become somewhat abruptly converted from (so to say) keepers to the shunt-magnets into magnets, and their rise of magnetism is at nearer saturation somewhat rapid. I think Dr. Ernst Richter has obtained similarly better results with separately wound machines, although the machines he tested were not in the best proportion, as far as may be judged by his figures.

Mr. Macgregor adverts to my earlier endeavours to make a machine self-regulating in series. This has long been a hobby of mine, but I have only recently attained practical success.

My object has been to charge several batteries of accumulators at different stations in series, and to be independent of all switches, which do not always perform their duty.—Yours, &c.,

PAGET HIGGS.

MEASURING THE EARTH-RESISTANCE OF LIGHTNING CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On various occasions much interesting and valuable information has appeared in the columns of *The Electrician* on the subject of the testing of lightning conductors; but there is one point which, to the best of my recollection, has not been referred to—viz., the correction or elimination of the effects of the current due to the difference of potential of the earth plates.

For example, suppose the conductor has a copper earth-plate, and the earth-wire from the Wheatstone bridge is fastened to the iron water or gas pipes, then owing to iron being electro-positive to copper—on completing the circuit—a current will flow from the iron, through the ground to the copper, and thence through the leads-bridge, &c., back to the iron "earth."

If a galvanometer be placed in this circuit the unsteadiness of the deflection will not only show the presence of this current, but also the variation in its strength due to polarisation of the earth plates.

Hence, the way in which we connect up the testing battery becomes of importance. With the earth plates above mentioned, we should, by joining the battery so as to put copper to earth (*i.e.*, iron water pipe) and zinc to line and conductor, reinforce the E.M.F. of what I may be allowed to call the earth battery; while by reversing the testing battery, so as to put copper to conductor and zinc to earth, we should oppose, and, in fact, overcome this counter E.M.F. of the earth plates.

In short, in the first position the available E.M.F. would be the sum, and in the second the difference of the testing and earth batteries respectively.

Figs. 1 and 2 will make this apparent, where the *thin* arrows show the direction of the current due to earth plates, and the *thick* arrows that due to the testing battery.

In the series of measurements tabulated below—the ordinary form of Post Office bridge, a Wheatstone-Daniel cell, and a Thomson reflecting galvanometer of low resistance being employed—I obtained the following values:—

	I.	II.	III.
With iron water pipes for testing "earth":—	Ohms.	Ohms.	Ohms.
Copper to earth	31	46	24
Zn to earth	97	50	35
With iron gas pipes for testing "earth":—			
Copper to earth	35	44	22
Zn to earth	100	44	36
Resistance of water and gas main:—			
Copper to gas	2·54	2·54	1·6
Zn to gas	1·76	1·76	1·3

I. Brass rod driven deep into moist earth, to represent conductor and its earth plate.
II. Iron rod substituted for brass one in I.
III. Actual lightning conductor of copper rope, several feet being buried in moist earth, but no plate.

Of course the reason for taking three sets of measurements, viz., firstly, of the conductor with water main for earth; secondly, with gas main for earth; and, lastly, of the water and gas mains together, is to obtain the actual resistance in ohms to earth of the conductor.

FIG 1

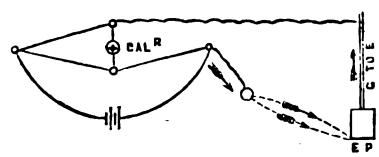

FIG 2

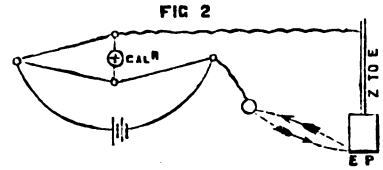

But the object of my writing is not to deal with this part of the subject, but to inquire what value are we to take as correct in such a case as Example I. Where we get with copper to earth 31 ohms, and with zinc 97 ohms, would it be safe for practical purposes to take the mean?

The case is somewhat analogous to a telegraph line traversed by an earth current, and for testing the resistance of such a line or cable Mr. Kempe, in his "Handbook of Electrical Testing," gives an elaborate formula, adding, "that several modifications of this formula have been suggested, but are only applicable under certain conditions (not stated), and as the formula is seldom required it is better to use the one given." But I venture to suggest that the data given above show that in testing lightning conductors some such formula will be in constant requisition, and my object is to ask Mr. Kempe or some other reader of "ours" to kindly favour me with a simple and yet approximately correct formula for calculating the true resistance from the observed.

I am aware of the method mentioned by Mr. Kempe of opposing this E.M.F. of the earth plates by interposing a standard Daniell cell with large plates shunted down till no current flows in the circuit in its normal state; but although I have obtained fairly good results with it, it is, to say the least, somewhat cumbersome when employed away from home Besides, the change produced by polarisation of the earth plates renders necessary a constant alteration of the "shunt." Apologising for the length of my letter—Yours, &c,

W. H. WHITEHOUSE.

Midland Institute, Birmingham.

P.S.—Since writing above I find that your correspondent "A. J.," page 109, Vol. XI., incidently refers to this subject,

Digitized by Google

and states that galvanometer must be balanced to "false zero." Would he kindly explain the method?

INDUCTION IN TELEPHONE CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your last issue an article entitled "Induction in Telephone Circuits," by Mr. F. W. Neale, of Stoke-on-Trent, in which the writer details the results of experiments made by him with induction coils placed mid-way in telephonic wires, with the object of neutralising the effects of induction to and from neighbouring conductors.

I am sorry to disturb the gratification that Mr. Neale probably experiences in having brought his two years' labour to a successful issue, and I am far from questioning the perfect independence of his invention, for I know how liable are two minds, when working with the same end in view, to coincide in their conclusions; but if he will refer to my patent, No. 4,428, of 1881, he will find the invention described and figured substantially as in his article. In that patent three plans are set forth for neutralising the effects of induction in parallel wires. Of these, Mr. Neale's is the second, and is marked Fig. 5 on the sheet of engravings. Even the methods he describes of ringing through and past the translator, although not included in the patent, have all been anticipated. The patent is now the property of the Electromotive Force Company (Limited), of 6, Hanover-street, Glasgow, with whom Nr. Neale will doubtless have to arrange if he wishes to continue the use of the apparatus.—Yours, &c.,

A. R. BENNETT.

National Telephone Company (Limited),
8A, Royal Exchange, Glasgow.
December 1st, 1884.

PAYING FOR SPECIFICATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to trespass on your valuable space to draw attention to the latest phase of the confidence trick as applied to electric lighting.

One of the most recently-established firms of electrical engineers and consulting electricians are asking, under the powers vested in them by the Grosvenor Gallery proprietors, three guineas for their specification, which three guineas are not returnable. We believe that people asking for estimates for electric lighting should be prepared to pay from one guinea to twenty guineas, according to the amount of trouble involved in the estimate, but this newly-formed firm seems to think that other electrical engineers are in such a scramble for work that they will in the aggregate part with a nice 100 guineas for the pleasure of competing for a new job.

I have declined to be a party to this arrangement, and I trust all other electrical engineers will join us in our decision.—Yours, &c.,

ENGINEER.

[We should be glad to know if the general feeling of electric light engineers is against payment for specifications, and willingly open our columns for a discussion of this question.—ED. *E.*]

A GENERAL INDEX.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A correspondent in your issue of November 22nd makes suggestions for further facilities for reference to back volumes of *The Electrician*. I would add a suggestion referring to back numbers of the current volumes.

Until the volume is completed by the appearance of the index with the final number, a reader wishing to refer back to any article is obliged to turn to the middle of each number for the table of contents, unless he has made special notes for himself on the outer sheet.

I would suggest that the headings of the principal contents should be placed in three or four lines at the top of the outer sheet, above the title of the paper (as, for example, Mr. Proctor now does in *Knowledge*, with so much advantage to his readers). This would enable a reader rapidly to pick out any desired article, without opening and turning over many numbers in his search.

Failing this, the removal of the "Contents" to the first page of "Notes" might be an advantage, though as it would require the reader to first take off the advertisement sheets, the facilities for rapid reference would be reduced.—Yours, &c.,

SUBSCRIBER.

December 3rd, 1884.

"DIE ELEKTRISCHE BELEUCHTUNG."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. J. Springer, publisher, Berlin, has sent you a copy for review of my recent work on electric lighting, and I beg to draw your attention to a mistake which has escaped correction. At page 41, line eight from bottom, instead of "Gleich" read *Klein im vergleich zu.*

In the event of your reviewing my work, will you have the kindness to point out the mistake to the reviewer, and to make the correction?—Yours, &c.,

PROFESSOR DOCTOR E. HAGEN.

Dresden, Altstadt, 27, Lindenau-strasse, Nov. 24, 1884.

[Our notice of this book will be found on p. 571, Vol. XIII. —ED. *E.*

THE LIGHTING AT THE VICTORIA STATION.

One of the finest metropolitan installations is now in working order. There has been no public announcement of its opening, but as descriptions of it have commenced in contemporary publications we do not feel bound to the silence hitherto kept, in deference to wishes conveyed to us some time ago when inquiring into details of the installation for publication. The arrangements for lighting the Victoria Station by means of electricity were settled with the Swan Company, and carried out by Messrs. Crompton and Co. The work, of course, has been under the United Edison and Swan Company, since the amalgamation. We have often referred to examples of Messrs. Crompton's installations, but we do not think that any of their work contains greater proof than this Victoria installation of the ability of the firm to carry out in the best possible manner the work entrusted to their charge.

An electric light installation consists of three parts. The first supplying the motive power, in this case steam; the second generating the electrical energy; and the third distributing and utilising that energy. Taking the Victoria installation in this order, the steam required for the engines is generated in three boilers of the locomotive type, illustrated below. These large locomotive boilers were designed at Mr. Crompton's request for this special purpose by Mr. W. H. Maw, C.E., who designed the boilers at the *Daily Telegraph* offices, and who has probably had more experience on this class of boiler than any other engineer in England. The objects of the design were to get into a small space of 20ft., over all length, by 5ft. wide and 8ft. high, a boiler capable of generating steam sufficient for 200 horse-power with great ease and economy. This these boilers have certainly succeeded in doing. Repeated trials have shown that they evaporate from 9·06 to 9·08 of water per lb. of Welsh coal, and this without any sensible priming. The power of each boiler is fully 230 horse-power—that is to say, they are capable of evaporating about 90 cubic feet of water per hour with the natural draught. Steam can be got up in about 35 miuutes, if the power is suddenly called for The whole of the fittings have been very carefully thought out by Mr. Maw; the water gauges have Dewrance's patent asbestos packed cocks, and they are in duplicate, and can be worked from either side by levers extending across the front of the boiler. This is a great convenience in the case of the

gauge glass breaking. The lever safety valves, back-pressure valves, and many other of the fittings are of special design, and not being a regular article of manufacture, had to be made specially by Messrs. Crompton themselves. The draught is supplied by an octagonal chimney, 5ft. internal diameter, 129ft. high. This gives ample natural draught for the present requirements, but if at a later period the boilers are required to supply steam for additional engines, they have been so

arranged that the Willans patent fan draught can be applied to them, which will increase their evaporating power sufficiently to make them equal to nearly double their present output of power. The makers are Messrs. Hick and Hargreaves, of Boulton, and the material of the plates is mild steel specially tested. Strips were cut from every plate, and subjected to very severe tests, and the test strips have in all cases been preserved. Altogether we may consider the boilers as very favourable examples of the most recent practice in this particular line. The following details will be interesting to all engineers :—

THE ALTERNATE-CURRENT MACHINE AS A MOTOR.*

BY PROFESSOR W. GRYLLS ADAMS, F.R.S., PRESIDENT.

In July last, whilst engaged in testing the efficiency of alternate-current magneto machines at the South Foreland, for the Elder Brethren of the Trinity House, it was suggested to me by Dr. Hopkinson to try the experiment, which was shown by him to be possible in his lecture before the Institution of Civil Engineers last year, viz., the running of two alternate-current magneto machines together, without clutching them on the same axis, in order to supply current to an external circuit.

The machines now being tested at the South Foreland are three De Meritens alternate-current magneto machines of the largest size made by him, having 60 permanent magnets, arranged in 5 rings of 12 magnets and 24 coils on each ring of the revolving armature. Each coil consists of four layers of wire, and is 27 millimetres deep and about 100 millimetres wide. The 120 coils when arranged in parallel circuit for lighthouse work have a resistance of about one-twentieth of an ohm. The internal resistances of the three machines are ·044 ohm, ·049 ohm, and ·056 ohm.

The five rings of coils on each of the machines are connected in parallel circuit when all the brushes are down, but the collectors and brushes on each machine are made in three sections, so that it is possible to employ one ring only of magnets and coils, or two rings only, or the remaining three rings, or the whole five rings together, by bringing the respective brushes in contact with their own collectors, which are insulated from one another by ebonite rings or flanges on the ebonite axis which insulates the collectors from the axis of the machine. The diameter of the armature carrying the revolving coils is 2ft. 6in., or 760 millimetres, and the driving pulley is about 16in., or 400 millimetres, in diameter.

When revolving at the normal speed, 600 revolutions per minute, the magneto machines have been found to work with very great steadiness and with great efficiency. The electro-

* Paper read before the Society of Telegraph Engineers and Electricians on Thursday, Nov. 13th, 1884.

Digitized by Google

motive force is about 75 volts and $\frac{2\pi\gamma}{T} = \cdot 3$ ohm nearly. When running with the circuit open, a very considerable amount of work is spent on the friction and internal work within the machine, but on closing the circuit this is greatly diminished, and the output of the machines, or the electrical energy in the external circuit, exceeds the *additional* work done to produce it. Thus a single machine absorbs 4·2 horse-power when running at 600 revolutions with the circuit open, yet only absorbs 10·4 horse-power with the circuit closed with one arc lamp in circuit, when it yields in electrical energy 6,000 watts, or 8 horse-power, in the external circuit. These watts are obtained by multiplying the average electromotive force, as given by Cardew's voltmeter, by the average current as given by Siemens' electro-dynamometer. This product will give a result which, according to Dr. J. Hopkinson's calculations, is above the true value.

The electromotive force was also determined by a quadrant electrometer, by joining the needle to one pair of quadrants, when the expression for the electromotive force becomes $(V - V_1)^2 = E^2 = \frac{2d}{k}$, where d is the deflection, and k the constant of the electrometer.

The method of determining the work done in the arc by joining the pairs of quadrants of the electrometer to the two ends of a known resistance placed in the circuit, according to the formula

$$d_1 = k\,(V_1 - V_2)\left(V - \frac{V_1 + V_2}{2}\right) = k\,C\,r\left(V - \frac{V_1 + V_2}{2}\right),$$

was also tried, but the introduction of even a small resistance, r, materially altered the electromotive force and also the current in the circuit, and the method was not sufficiently sensitive. Thus, when the deflection by the first method, or $\frac{k}{2}(V - V_1)^2$, was 120 divisions of the scale for an electromotive force of 57 volts, the deflection by the second method was only about 30 divisions when r was about one-fifteenth of an ohm. The addition of this resistance considerably increased the electromotive force, and diminished the current in the circuit.

At the South Foreland the leads from the machines to the arc lamps in the experimental tower have a resistance of ·066 of an ohm, and when two machines were clutched together and working in series, so as to supply two arcs in series, the yield of electrical energy per second was about 10,200 watts in the external circuit; whereas, when working in parallel circuits through the same leads to one arc lamp, the yield was only about 8,600 watts in the external circuit.

To test whether alternate-current machines would work in harmony without being rigidly made fast on the same axis, two machines which are usually clutched together were set running, being joined in parallel circuit, and when they had attained their usual speed of about 600 revolutions a minute they were unclutched, and each was driven only by its own belt. The two machines continued to run together very steadily, mutually governing one another; the electromotive force remained steady at 75 volts on open circuit, the same as the electromotive force of one of the machines which had been previously tested.

The machines were not quite equal in efficiency, for before this experiment one of the single machines had given a current of 135 amperes, and the other 165 amperes, with electromotive force of 37 volts, at the normal speed of 600 revolutions; now on closing the circuit from the two machines through the arc, the electromotive force became steady at 40 volts, and there was a current of 221 amperes, giving 8,800 watts in the external circuit, and the machines continued to run as steadily as if they had been clutched.

The lamp was now put out of the circuit and the machines short circuited upon one another, without the slightest danger to the machines, owing to their high coefficient of self-induction. The belt was then thrown off one machine, when it continued to run at the same uniform speed, being driven as a motor by the electric current from the other single machine, and the electromotive force was equal to the electromotive force of the machine on open circuit.

An attempt was now made to introduce an arc into the circuit, but the motor immediately began to lose its speed and the arc became fitful with long beats, as in two musical instruments getting out of harmony, the beats increasing as the speed fell and the machine stopped.

A third machine similar to the others, but not placed on the same axis and having no mechanical connection with them, was also driven as a motor by one of the other two machines.

These experiments were repeated, and some other interesting experiments made, on October 18th, when Dr. J. Hopkinson went with me to the South Foreland.

Two machines were started together, but independently, each being driven by its own belt, and they increased their speed in harmony, always going together until they reached their normal speed, when the electromotive force rose to 80 volts. The belt was now thrown off one of the machines, when the electromotive force at the terminals of the driving machine remained at 80 volts. A strap was placed round the pulley of the motor machine, and a weight of 14lb. was hung on the strap; the machines continued to run together, but the electromotive force oscillated from 80 to 78 volts as the weight rose and fell with the pull on the strap, being not heavy enough to give a steady pull. Thus one machine was being driven as a motor by another equal machine, and was doing work which was measured by the friction brake. The pulley was 16in. in diameter, and the speed 600 revolutions, giving 35,200 foot-pounds per minute, or more than 1 horse-power.

On putting on 28lb. on the pulley of the motor, the electromotive force was reduced from 80 volts to 78 volts, and remained steady, and the machines still ran together. On putting 42lb. on the brake on the pulley of the motor, the electromotive force was reduced to 76 volts, and then 56lb. was put on, when the motor continued to run at the same rate as the generator, and the electromotive force was steady at 74 volts.

On account of the heating of the extemporised brake strap, it was not thought advisable to continue the experiments by adding heavier weights, although there seemed to be every probability that the machines would continue to run together at the same speed, the one as generator and the other as motor and doing work. The above experiments show that the work done on the brake was 140,000 foot-pounds per minute, or more than 4 horse-power.

In another experiment the three machines were started together, and run up to their usual speed of 600 revolutions per minute, each machine being driven by its own belt. The belts were then thrown off two of the machines, and they were driven as motors by the current from the third machine, the electromotive force at the terminals of the third machine being the same as when the three were running together in parallel circuit.

(TO BE CONTINUED.)

ON THE ELECTRIC LIGHT.*

BY ALFRED RICHARD SENNETT, A.M.I.C.E.

(CONTINUED FROM PAGE 60.)

Before considering the other apparatus employed in electric lighting, it will be interesting to glance at the relation which lighting by the electric arc bears to other methods of illumination. As regards—

Heating.—The thermal effects of the electric arc, as of all other sources of light, are due far more to the rays of longer than to those of shorter wave-length, but with the electric light it is very pronounced. The ratio of the invisible to the visible radiant energy of the sun is about as 2 to 1, whilst in the electric arc it is nearly as 8 to 1 (Tyndall). The area of the incandescent body in the electric arc is so diminutive when compared with the area necessary to produce an equal amount of light from gas, oil, or other source, that although the temperature of the former is so much more elevated than that of the latter, yet the rise in the temperature of the surrounding air, due to convection, is infinitesimal when compared with that due to gas and other sources of illumination producing a light of equal power. In order to illustrate this, the electric arc may be viewed as an ordinary domestic fire, from which nearly

* Paper read at a Supplementary Meeting of the Institution of Civil Engineers.

Digitized by Google

the whole of the air deriving its heat by convection passes away by the chimney, since in the arc the heating by convection may be nearly neglected. The remaining energy is spent in communicating oscillatory movements to the luminiferous ether. The waves thus produced do not heat the air in their passage through it, but are converted into heat only when they traverse an absorbent medium, or impinge upon the walls, ceiling, floor, &c., of the apartment, and it is from these latter that the air derives its increase of temperature. The heating effect, then, of the electric light in an open space may be said to be *nil*. In a confined space, a rise in the temperature of the air will take place proportional to the energy expended in the arc. Since, however, the amount of light produced per unit of heat so expended is so much greater than by other means, the air will receive a much smaller increment of heat by this than by other methods of illumination. For the purpose of comparison imagine a chamber, say 50ft. square by 20ft. high, from which no loss of heat can take place, to be illuminated for ten hours by a light equal to that given by 4,000 standard candles, the light being produced respectively by the electric arc, by incandescent electric lamps, by gas, and by candles. At the end of the ten hours the temperature of the atmosphere of the chamber would be raised :—

	Centigrade. °	Fahrenheit. °
By the Electric Arc	0·706	1·27
By Incandescent Electric Lamps	7·0	12·6
By Gas	78·4	141·0
By Candles	190·0	342·0

In other words if, at the commencement of the ten hours, the atmosphere of the chamber had been at the ordinary temperature (16° Centigrade, or 60°·9 Fahrenheit), then at the expiration of the ten hours it would have been raised :—

	Cent. °	Fahr. °	Cent. °	Fahr. °
By the Electric Arc from	16 or	60·9 to	16·7 or	62·1
By Incandescent Electric Lamps	16 ,,	60·9 ,,	23 ,,	72·9
By Gas	16 ,,	60·9 ,,	98·4 ,,	201·8
By Candles	16 ,,	60·9 ,,	206 ,,	402·8

Secondly, as regards the products of combustion :—

Vitiation of the Atmosphere, due to various methods of Illumination.—Compared with other methods of illumination the products of combustion from the electric arc are very small. In order to obtain a comparative review of the amount of defedation consequent upon the employment of the more important illuminants, reference will be made to the before-mentioned 4,000 candle power and to the hypothetical chamber. The amount of carbon consumed during the ten hours would be about 1,750 grains, and this, combining with the oxygen of the atmosphere, would yield 6,413 grains of carbonic anhydride (CO_2)=7·4 cubic feet (barometer 30in). There would also be a small amount of nitrous acid as nitrites, probably about 771-5 grains of nitrous anhydride.

The amount of these products will depend upon the position of the arc, whether it is confined or if the air is permitted to play freely around the poles, also whether the carbons be placed horizontally or vertically; if placed horizontally the amount of the products will be much greater. There will also be a slight trace of sulphur, as the author has found this in all the well-known carbons ; it will probably be given off as sulphurous anhydride (SO_2). In order to facilitate comparison, the author has drawn up the following table, showing the carbonic anhydride, &c., produced per hour from an equal amount of light derived from the sources mentioned :—

PRODUCTS OF COMBUSTION FROM VARIOUS ILLUMINANTS.

* Combines with O to form SO_2, and this, combining with O and H_2O, forms H_2SO_4.

It will be observed that no absolute value can be given to express the relation between the electric arc and other methods of illumination as regards their effect upon the purity of the atmosphere, since the efficiency of the arc (in respect of illumination) varies with the amount of electrical energy passing between the electrodes ; whilst the amount of light obtained from the combustion of a given volume of gas depends upon its quality, upon the burner or manner in which the chemical combination is accomplished, and upon the temperature at which the chemical combination is effected. With regard to oil and candles, doubtless the effect of concentration of heat in varying the propertion of luminous to obscure radiation will hold good in these cases also ; for although a given weight of paraffin or stearine can only potentiate a definite amount of energy, there are several forms in which this energy may be taken from it.

Referring again to the hypothetical chamber, it would have been necessary, in order to reduce the amount of defedation of the air as regards CO_2 to the standard of that of the air of a manufacturing town, to have changed the whole of the air in the chamber during the ten hours, as given in the second column. The first column showing the relative amounts of CO_2.

Actinic Power of the Electric Arc.—The spectrum of the electric arc is very long, due to prolongation both at the infra red, and ultra violet ends, but its length varies with the length of arc. The spectrum of the incandescent electric light is similar to that of candles, &c. ; but it varies greatly with the temperature to which the filament is raised, the proportion of luminous to obscure rays being in the arc about 1 to 9 (Tyndall 50 groves), in gas 1 to 24, in white hot platinum wire 1 to 23.

The actinic effect of the electric arc depends on three factors, one of which is constant and the other two variable. The constant factor depends on the current, since it varies with the area of the crater ; the other variables depend on the kind of carbon employed for the electrodes and upon the length of the arc.

The author thinks it advisable to point out the conditions which he has found favourable to the development of actinic action on a given surface.

First, a very long arc should be employed.

Secondly, a line normal to the plane of the specimen should form an angle of from 30° to 50° with the axis of the carbons, if these are placed vertically and the axis of one carbon is coincident with the axis of the other. He has found it more convenient, however, in many cases to arrange the carbons as in military and naval lighting, by which the rays of greater refrangibility proceeding directly from the crater are utilised. The observance of these conditions is obviously of great importance, when it is required to obtain the maximum speed from a given arc in the printing of photographic transfers, &c. Upon plotting a number of results it was found that the curve of actinic effect was practically coincident (especially for moderate powers) with that of illuminating power.

Penetrative Power of the Electric Arc.—There appears to be a marked distinction between the quantity and intensity of a light. Just as by increasing the velocity of the armature of a dynamo-electrical machine an increase occurs in the quantity and (to use an obsolete expression) the intensity of the current, so in augmenting the temperature of an incandescent body both the quantity and the intensity of the light increase. An analogy may be drawn from a musical sound, a vibrating string for example. In a musical sound the timbre or character of the sound is dependent upon the character and number of sounds of different and shorter wave-length which are combined with the fundamental sound, whilst the character of a light is dependent upon the character and number of rays of different and shorter wave-length combined with that of the principle wave-length or fundamental light. In the former, by striking the string with varied force and in a different manner the proportion of these sounds of various wave-length to the fundamental wave-length may be altered, and with it the character of the sound produced. So, by increasing the temperature of an incandescent body, the proportion which the rays of various and shorter wave-length bear to the fundamental wave-length is altered, and with it the character of the light. That is to say, while the amplitude of original vibrations is increased, new ones of shorter wave-length are produced, and thus the light changes in character and becomes more intense. But does this increase in intensity signify increase in penetrative power ? or rather, is the amplification in the power of penetration

Digitized by Google

due to increased power on the part of the slower vibrations, or to the introduction of the new and more rapid ones? This will depend upon the character of the obscuring medium; for it must be remembered that the more rapid the vibrations, the more refrangible are the rays they produce, and hence it may be that one set of vibrations or character of light may be suitable for traversing a dry obscuring medium, such as smoke, and another series may be more adapted to the permeation of a humid medium, a fog or mist for example.

In a damp obscuring medium, such as fog, the rays of shorter wave-length have the greater penetrative power. One method of observing this is to mount an eminence and look along a straight road lighted by gas or electric lamps. It will be observed that each successive light farther from the observer has a more yellow, and in the remote ones a more ruddy, tinge than the preceding ones, and that the farthest light will be of a decided red as compared with the nearest. The great change in colour in the rising moon on misty evenings may be cited as another example. These facts go to show that the beacon fires employed in olden times were well adapted to fulfil their requirements, and also that for light-house illumination and other positions where penetrability is the desideratum, very strong currents producing large masses of heated pole, a short arc, and a small difference of potential between the poles (say 60 volts), should be employed.

Distribution of Light from the Electric Arc.—As in almost every source of illumination, the light produced by the electric arc is

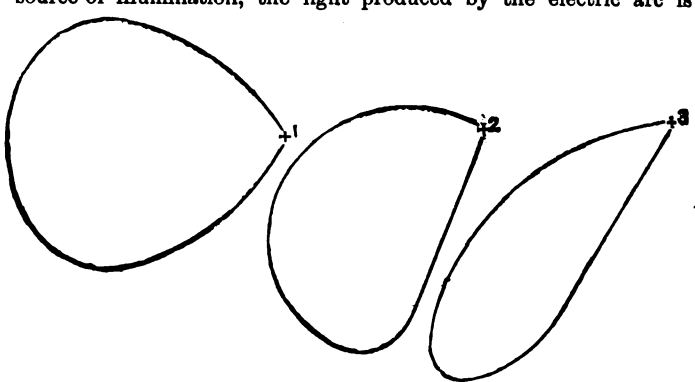

Fig. 7.

not emitted uniformly in all directions, its amount, colour, and distribution depending upon several conditions. The amount depends on the electrical energy in the arc, the length of arc, and the chemical composition of the electrodes; the colour on the length of arc, the character of current employed, and the composition and density of the carbons; the distribution on the length of arc, the character of the current, and on the carbons themselves. The annexed diagram (Fig. 7), show the distribution of light from various arcs: 1, when an alternating current is used; 2, an arc of moderate size produced by a uni-directional current; 3, a short arc and small uni-directional current.

For general illnmination and industrial purposes the positive electrode is usually placed above the negative, its axis being vertical and forming a prolongation of the axis of the negative; but for special purposes it is sometimes advantageous otherwise to dispose the electrodes. In search lights, for example, the upper carbon is generally placed in the rear of the lower, so as to expose the crater toward the front. For lighting with vertical carbons, the author prefers to employ an upper carbon of about 3 or 4 millimetres greater diameter than the lower.

LEGAL.

Important Decision as to Rating Telephones.

THE LANCASHIRE AND CHESHIRE TELEPHONIC EXCHANGE COMPANY (APPELLANTS) AND THE OVERSEERS OF THE POOR OF THE TOWNSHIP OF MANCHESTER (RESPONDENTS).

(Before the MASTER of the ROLLS and Lord Justice LINDLEY.)

This was an appeal from the judgment of Mr. Justice Mathew and Mr. Justice Day, in the Divisional Court of Queen's Bench, on the 3rd July, 1884, on a case stated to them, the facts being these:—

The Lancashire and Cheshire Telephonic Exchange Company were incorporated under the Companies Acts on the 21st May, 1881, for the establishment and maintenance of a telephonic exchange by means of which any one subscribing to the exchange could communicate privately by telephone with any other subscriber, and for the supply and erection generally of wires and telephonic apparatus not in connection with the telephonic exchange, for the private use of firms and individuals paying a rent for the same. The company acquired by purchase the local telephonic business of Messrs. David Moseley and Sons and the Edison Telephonic Company, and for the purpose of their undertaking laid wires, some underground and some overhead, which latter were supported by poles and standards and other attachments to the houses, the company entering into an agreement with the owners, by which they paid a nominal rent for leave to make the attachments, and undertook to remove them when required by notice so to do. In June, 1883, the respondents, the overseers of the poor for Manchester, made an assessment rating the company as occupiers of their offices in Falconer-street, Manchester, and of land, telephone posts, and wires in the township, at a gross rental of £2,400, and a rateable value of £2,000. The company admitted liability with respect to their land and premises, but not as to the wires. On the special case it was argued on behalf of the company that the wires and supports did not create such an occupancy by the company as to be rateable; while for the overseers it was contended that, following the decision in the Salford case (Exch. 11), there was such an occupancy as to be rateable under the statute of Elizabeth. The Divisional Court took this latter view, and decided for the rate. Against that decision the Telephone Company now appealed.

Mr. Collins, Q.C., and Mr. Webster, Q.C., appeared for the appellants; and Mr. Ambrose, Q.C., Mr. Smyley and Mr. Overend Evans for the respondents.

Mr. COLLINS, for the appellants, argued that the mere fixing of the wires to the roof of a house did not create any tenancy in the land or the premises, and distinguished the case from that of telegraph posts, because of there being no demise, but simply a license revocable by notice to affix the supports, which made an easement, but not one that was rateable. In support of this view he cited a case where mooring a barge to a wharf by license was held not to create a rateable occupancy. Referring to the case of Smith's bookstalls, which were held not to be liable, he argued the case of the wires was similar in not, from the terms of user, creating a rateable tenancy. The case of Willing's advertising boards was even more in point, for there certain things were fixed to walls, and it was held they did not create a liability. For the purposes of a rate there must be an exclusive and separate occupancy, which he maintained could not be proved, or even if it existed it could not be attributed to the Company.

Mr. AMBROSE, for the overseers, submitted that however the wires might be fixed they were in the sole and exclusive occupation of the Company, and created an occupancy by them in the premises and land underneath which supported them. The telegraph posts were rateable in consequence of the user of the land, even though that was subject to notice by the railway companies by the side of whose lines they were placed; and the fastenings of the telephone wires were in the same position. He further maintained that the sole occupancy of the wires created a rateable occupancy by the company in all that was underneath them, whether fixed or not.

The MASTER OF THE ROLLS, in giving judgment, said the real question was with regard to the spikes and saddles and brackets fixed to the houses for the purpose of carrying the wires, and it was obvious that the wires were accessories, so that the company were liable in respect of the things fixed to the house. The wires were fixed to the brickwork or to the wooden roof, and were part of so much of the roof as was necessary to support them; for, take away the rest of the roof, and you will have a certain support. They were supported by the building, which was supported by the soil, and were therefore supported by the soil, and so much of the soil as was necessary to support the wires was occupied by them. It was not like the right to hang things to something fixed to the soil for the purpose. There were things which might be the subject matter of the occupation by the persons occupying them. Who was in the occupation of the wires? They were the property of the company, the exclusive property, and used exclusively by them as between the company and the owners of the houses, solely for the benefit of the company and not for the benefit of the owners. It seemed that the company was in occupation of every part of the house which could be made use of for the wires, and they were in occupation of what was rateable. The attachments had become part of the realty by the manner in which they were fixed to it. It never was intended that any copartnery should exist, or that these things should ever belong to the owner of the house, the exclusive ownership and right to deal with them being in the company. The case was like that of the telegraph posts, and there was no reason why the rule laid down in the Salford case should not govern it. The appeal must be diemissed with costs.

Lord Justice LINDLEY concurred, and the appeal was accordingly dismissed.

Mr. COLLINS gave notice of appeal to the House of Lords.

COMPANIES' MEETINGS & REPORTS.

The Gulcher Electric Light and Power Company (Limited).

The second ordinary general meeting of this Company was held at the Offices of the Company, 4, Coleman-street, Bank, on the 4th inst. Mr. Daniel de Castro presided.

The SECRETARY (Mr. Russell Day) read the minutes of the last meeting, which were confirmed, and the notice convening the present meeting.

The CHAIRMAN said the resolution he had to propose was in rather an unusual form. It was as follows:—"That the report and accounts of the Directors as presented to the members at this meeting be adopted and approved; and that the sum of £162 11s. 2d., part of the £1,776 18s. 10d. standing on the 30th September, 1884, to the credit of the trade and other

Digitized by Google

debts, and the sums of £880 12s. 6d., £125, and £85 11s. 7d., part of the sum of £1,963 19s. 1d. respectively standing in the books of the Company to the credit of Directors' fees, Mr. H. Crookes' salary account, and W. Crookes, Esq.'s, F.R.S., loan and interest account, be treated as claims only." He then referred, in explanation of the unusual character of the resolution, to the position of the previous report and accounts, and to the opposition which he made to the passing of those accounts; and afterwards stated that he asked them now not to treat all the credits which appeared in the books of the Company as credits, but to treat some of them as claims only. On the 30th of June, 1883, the accounts showed that their capital was £168,000, their liabilities £172,000, and they had £19,000 of creditors. Their stock and plant together were less than £20,000; their trade debtors were £1,100, and their cash was £2,560. It was not until the 28th September, 1883, that the new Directors were elected, and at that date the position was a very different one indeed from that represented by that balance sheet. When they came into power Mr. Crookes was their Chairman, and with one exception, his (the speaker's) co-Directors supported Mr. Crookes. Their liabilities at that date were greater than the £19,000 mentioned. There was a bill of sale over their property for over £11,000; and the cash balance, instead of being £2,600 odd, was only £227, out of which they had to pay £170 for wages of the week on the Tuesday when they took office. When they took office the debts of the Company were twice—and a great deal more—what they were now; and the cash balance was £50. The fifth call had been made, and it had been mortgaged to the same gentleman who held a bill of sale over their property. There was £1,000 carried to the credit of the Company as a deposit on a concession sold to a Scotch Gülcher. With £57 in the bank, the bill of sale hanging over them, not a "rag" of their property that they could call their own, before the new Directors had been in office three weeks they were told by an award of an arbitrator that they were to pay £1,000 and costs within ten days. That £1,000, it appeared, had been a subject of arbitration, of which the shareholders had heard nothing. He confessed that at the time he never dreamt that they would be able to pull through the almost impossible position in which they found the Company, but the Directors were a shareholders' Board—they were all *bonâ fide* shareholders, and they represented the *bonâ fide* shareholders. They resolved to go round to the *bonâ fide* shareholders, to state candidly the position of the Company, to tell them that if they wound up it seemed to him that they would lose everything, and to ask them whether they would make any advances to give the Directors time to try and pull the Company out of the mess in which they had found it. They concealed nothing. The result was that from a number of their powerful shareholders they received unlimited support, and with the money so obtained the Company had been placed in its present position. In ascertaining the real position of the Company he received great assistance from the late secretary of the Company. He got in that manner at the origin of the Company, and the result was that within three months all the shareholders against whom he had protested "threw up the sponge." They gave up £75,000 on account —£70,000 absolutely of the purchase money, which was supposed to have gone into the pockets of poor Mr. Gülcher; and they then thought that they saw a possibility for the Company. Mr. Crookes confessed that his position was so much improved by the result of the negotiations with the promoters of the Company that he unreservedly gave up £10,000 of his shares to further reduce the liability of capital hanging over them. Mr. Gülcher and Mr. Groth responded in an equally handsome manner. Their capital, by these negotiations, had been reduced, if he remembered rightly, from £196,000 to about £90,200. This reduction was not, however, yet absolutely completed. The balance-sheet now before the shareholders—going up to the 30th September last—was a miserable affair, but it was honest. It was, too, better than it looked. At some length he pointed to the position which it disclosed. The amount at that time acutally paid into the coffers of the Company by *bonâ fide* shareholders was £54,910, and the capital of the Company was then £108,653 11s. 8d., plus two amounts of calls in arrear, bringing the capital up to £116,000 or £117,000. At the time the sixth call was made he determined that if possible there should not be another call for at least twelve months, thus giving the poorer shareholders breathing time. The richer ones assisted him, as before, and paid their calls in advance, and others took debentures secured on unpaid calls; and authority was obtained from the shareholders to raise £10,000 on debentures. On the other side they had patents—after writing off nearly £20,000—standing at £55,000, and plant and tools £5,800. They knew the value of such assets in the event of a compulsory sale. Then their convertible assets were £125, a bill; £1,447 trade debts; and cash in the bank £17 7s. Since then the arrears of calls had been gradually reducing; and before the litigation there had been received on that account £1,350, £250 on account of the debentures issued but not yet allotted; and of the trade debts they had received at the date of litigation about £1,200. That was all the result of six weeks; and against the £1,200 received on account of trade debts they had added £1,034 new assets. Their liabilties at the 30th September certainly amounted to £3,924, but of that sum the trade creditors were £1,776, and Directors' fees, salaries, loan, and interest, £1,953. In the six weeks, instead of having serious liabilities they had reduced the trade liabilities to less than £1,200; their disputed liabilities were still £1,343, and they had assets equal to their admitted liabilities, and without treating their patents or their plant as worth a snap of the finger, they had £527 to the good at the bank. An approximate balance-sheet had been made up to the 30th of November, and at that date they owed £9,950 to debenture holders, and about £106,000 to their shareholders, and they had no other debt in the world that he knew of. There was receivable upon a bill £125, £1,180 was due to them from trade debtors, and they had now at the bank £769. He had treated the patents as worth nothing, but he believed the Gülcher patents to be of great value. The stock stood at £18,000, and about one-third of it was earning income on hire. If the Company lasted over that day they had on their shelves now about £2,800 of stock, which he believed within a few days of the passing of the accounts would be earning the Company £25 a week. Therefore, £6,000 of their stock, if the Company continued, would be earning them at the rate of £2,000 a year. Their stock was appreciated by the Health Exhibition Commissioners, and he had been invited to apply for a better position in the Patents Exhibition of next year than they had hitherto occupied, and he thought of that stock they would be able to put out another £2,500, with very little expense, which would earn more than £900. There was a hope yet for the Gülcher Company. He next alluded to the legal proceedings against the Company by Mr. Crookes, Mr. Henry Crookes, and Mr. Norton. He warmly denied the allegations made by the last two gentlemen that the Company was insolvent, and strongly criticised the nature of the petition presented by both of them. Having spoken of the changes which had been made in the conduct of the business, and the economies thus effected, he stated unhesitatingly that more than half the losses of the Company had been due to the incandescent lamp department. They had, however, done all they could to make the Crookes lamp a success. It had at length been decided to bring an action against Mr. Crookes for misrepresentation. He put the case to Mr. Crookes thus:—If you had been a common grocer, and had sold me a chest of tea honestly believing it was sound, and it is discovered to be damaged, or that no tea can be made out of it, is it decent for you to refuse to return to us—even the money. But I do not ask for that. I ask for half the money, and take back your chest of tea. That was the position the Directors had taken up with Mr. Crookes, and that position he recommended them to pursue to the end. If there had been an obstacle to the success of the Company it had been the Crookes lamp.

Major COTTON seconded the motion.

A long discussion followed, and the CHAIRMAN replied *seriatim* to the questions asked. In answer to one gentleman he stated that the action against Mr. Crookes was for the return of his purchase money and the rescision of his contract on the ground of misrepresentation before entering into it, and consequential damages.

Mr. REEVES stated that he was the largest shareholder of the Company, and he moved an amendment that the accounts and report be received, but not adopted or approved, and that the meeting do stand adjourned to this day five weeks, and that a committee of the shareholders be appointed.

Mr. DAVIDSON seconded the amendment.

The CHAIRMAN, in the course of reply, and in answer to further questions, said that during the last six weeks there had been an unusual development of the inquiries as to the Company's light and of orders; and they were very much more inclined now than they were a few weeks ago to think that those inquiries might be developed into orders. He did not think that the litigation in connection with the Company would be endless, but he would say no more on that point. A five weeks' adjournment would ruin them.

He put the amendment and declared it lost.

Mr. DAVIDSON then demanded a poll.

On this demand considerable discussion followed, as to whether there were votes representing a fifth of the capital, which was necessary to support the demand.

The CHAIRMAN said that he was not going to burke an inquiry, but the capital of the Company was £22,572, and votes to represent a fifth of that amount must be held before he would grant the demand for a poll.

It was then found that with Mr. G. Monkland's proxy Mr. Davidson held sufficient voting power to demand a poll; and

The CHAIRMAN stated that the meeting would be adjourned for a week for the poll to be taken.

A letter was then handed up to the Chairman from Mr. Monkland, stating that he could not come to the meeting, and that under the circumstances he was not disposed to vote at all, adding that he had not been at the meeting, as stated, through a misapprehension by Mr. Davidson.

The CHAIRMAN on this (Mr. Davidson dissenting) ruled that there was no proper demand for a poll, which he would not grant. He afterwards put the original resolution, and declared it carried.

The Directors were afterwards re-elected; and Mr. Jackson was appointed Auditor.

A vote of thanks to the Chairman and Directors closed the meeting.

Railway and Electric Appliances Company, Limited.

An extraordinary general meeting of this Company was held on Thursday, at the Cannon-street Hotel. Colonel R. Jackson in the chair.

Mr. W. SHEPHERD (the Secretary) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, I shall endeavour to occupy as little of your time as possible in my preliminary remarks, but I shall afterwards be prepared to answer any questions that may be put by any shareholder, and to deal with any matters that may be brought before the meeting The object that the Directors have had in view in negotiating the arrangement which you are asked to confirm is to take one more important step in connection with getting the Company out of the realm of litigation which has been the bane of its career hitherto, and this compromise together with the compromise which you agreed to on the 18th April will have the effect of making a material change in the capital position of the Company. The shares which will be cancelled by the compromise which you are asked to sanction number 41,681, and the capital paid upon them has been £20,975 12s. 6d. You are asked, by the payment of £4,000 to get rid of the liability of £20,975 12s. 6d. If you agree to the proposal, the capital position of the Company will be as follows:—There will be 28,450 fully paid-up shares, and 50,051 ordinary shares,

Digitized by Google

upon which 12s. 6d. has been paid, the share capital of the Company being £78,501 against £172,232, which it stood at before the two compromises, and the capital which would rank for dividend, or for participation in the assets of the Company in case of liquidation, will be £60,256 7s. 6d., against £131,282. You will see, therefore, that the two compromises will materially improve the position of the shareholders who remain. I am sorry to say that the Directors have reason to be extremely earnest in urging you to get your affairs out of the hands of the lawyers. They attend meeting after meeting, and a large portion of their time is devoted to dealing with matters of litigation instead of the business proper of the Company, and it is most sickening to have to see what probably might be made a good business injured and depressed by the quarrels amongst ourselves, and what I cannot help characterising as needless and ruinous obstruction. Gentlemen, I will now move the following resolution :—"That the Directors be authorised and requested to compromise all or any of the actions pending against the Company on such terms as they deem expedient, including the removal of the plaintiffs, or any of them, from the register of members, and the payment out of the funds of the Company of a sum not exceeding £4,000 in respect to the compromise of claims of £20,000 or upwards." Gentlemen, I content myself with that.

Admiral INGLEFIELD seconded the motion.

Mr. MURRAY asked whether they were parting with any of their patents in this compromise?

The CHAIRMAN replied that the compromise bore only on the questions between the Company and the litigant shareholders, and it did not bear in any sense upon the right of the Company to its patents.

Admiral INGLEFIELD said that it would be satisfactory to know what funds they had in hand.

The CHAIRMAN replied the total assets amounted to £20,170, and there were liabilities amounting to £8,474, including the £4,000, so that there was a considerable balance in favour of the Company, independent of the uncalled capital, which they hoped not to have to trespass upon, and which would amount to about £19,000.

In reply to a further question,

The CHAIRMAN said that in addition to what he had mentioned they had the works at Palmadie, which were free from mortgage, and on which they could obtain a mortgage of from £2,000 to £3,000.

Admiral INGLEFIELD: What are the annual expenses of the staff?

The CHAIRMAN: The expenses at the works were, in salaries, £2,100, and they are now reduced about £600.

Admiral INGLEFIELD: Is any profitable business being done?

The CHAIRMAN: The position of the business is very materially altered in two or three respects. The Williams patents show now signs of becoming more valuable to the Company. I think there are indications that we may expect a business in the crossovers and other appliances of which we have the monopoly under the Williams patents. Then at the works there was lost nearly £6,600 a year, and over £9,800 in the eighteen months up to 30th June last. Since then in some months there has been a profit, and in some months there has been a loss; and on the balance for the last three months, including November, I am given to understand there will be no loss at all, so that we have been gradually and steadily improving the position of the Company, and I think if there were any improvement in trade, and if the expected demand for the Williams installation should increase, we may arrive at a period of profit at the Palmadie Works. In London the expenses have been very materially reduced. Formerly the expenses in London for office and salaries were £1,050, and for stationery £100, but now the amount is only £560. An arrangement has recently been made by which a reduction has been effected in the amount of the rent of the Company's offices to one-half. In addition to that another party has some accommodation in the office and pays half the rent, so that our rent will be reduced from about £400 a year to £100. I may add that some time back we bought a patent for the manufacture of waggon fasteners, and I am happy to be able to inform the shareholders that that has proved a very valuable patent. Our annual return from it will be considerably more than the amount we paid for it.

Admiral INGLEFIELD asked the amount of law expenses up to date.

The CHAIRMAN was afraid he could not answer that. There were about £1,500 to £2,000 outstanding.

The resolution was then put to the meeting, and carried with three dissentients.

Great Western Electric Light and Power Company.

The following notice has been sent to the shareholders of this Company, with a notice of an extraordinary general meeting:—

Gentlemen: Your Directors have convened an extraordinary general meeting of the Company to consider, and, if thought advisable, to confirm a provisional agreement entered into with the Anglo-American Brush Electric Light Corporation. This agreement embodies an offer, unexpectedly made by the Anglo-American Brush Electric Light Corporation, to take over your Company as a going concern, paying for each Great Western share 10s. in cash and 15s. in fully paid Anglo-American Brush shares at par. This offer your Directors consider a fair one under existing circumstances, but the responsibility of its acceptance or rejection must of course rest with the shareholders. It amounts briefly to this: you will receive the bulk of the cash now in hand, and you will receive in Anglo-American Brush shares at par the full face-value of all your plant, property, buildings, stock of materials, stores, &c., together with about £4,000 for the good-will of your business. You will thus become partners in the original Company, who have excellent works, a well-organised staff, and sufficient capital to carry out successfully contracts of a magnitude that your Company could not venture upon with the capital at their command. In order to ascertain the value of the Anglo-American Brush shares proposed to be taken in part payment, two of your Directors have had an interview with Lord Thurlow, the Chairman of the Anglo-American Brush Electric Light Corporation, at which the present financial position and future prospects of the Brush Corporation were fully disclosed; and these are, by your Directors, considered sufficiently good to warrant them in laying the present proposals before you. Should the proposed amalgamation be carried out, the distribution of 10s. per share in cash, and the issue of the fully paid Anglo-American Brush shares, will take place at an early date. Your Chairman, Mr. J. B. Braithwaite, jun., will also be invited to join the Board of the Anglo-American Brush Electric Light Corporation, and he will thus still have an opportunity of watching over your interests. Should you decide to reject the offer of the Anglo-American Brush Corporation, your Directors will continue to give their best attention to the affairs of your Company.

At the extraordinary general meeting of the Company, to be held at the Cannon-street Hotel, Cannon-street, on Monday, the 8th inst., at two o'clock, the subjoined resolutions, if deemed advisable, will be passed, which it is intended to submit to a subsequent general meeting for confirmation as special resolutions, viz. :—

1. That the conditional agreement submitted to this meeting, and made between this Company of the one part, and the Anglo-American Brush Electric Light Corporation (Limited), of the other part, be, and the same is hereby approved and sanctioned.

2. That with a view to carrying the said conditional agreement into effect, the Company be wound up voluntarily, and that Mr. Emile Garcke and Mr. F. W. Reynolds be, and they are hereby appointed liquidators for the purpose of such winding up.

3. That pursuant to the Companies Act, 1862, the said liquidators be, and they are hereby authorised and directed to adopt, on behalf of this Company, the said agreement, and to receive paid-up shares in the said Corporation, as consideration for the property thereby agreed to be sold in accordance with the terms of such agreement, and generally to carry the same into effect.

NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 5th Dec. amounted to £4,152.

PERSONAL.—Mr. Joseph S. Beeman, A.M.I.C.E., M.S.T.E., engineer and electrician, has opened offices for private practice at 48, Imperial-buildings, Ludgate Circus, London, E.C.

THE TELEPHONE IN FRANCE.—Between the 27th November and 4th December of this year, the Société Générale des Téléphones enrolled 25 new subscribers in Paris alone; and, between the 23rd and 29th November, four at Bordeaux, one at Marseilles, and one at Nantes.

ELECTRIC LIGHT IN THE HOUSE.—It was intended to considerably extend the partial use of the electric light in the House of Commons before next session; but the autumn session has prevented the work from being carried forward, and it is now indefinitely postponed.

HENLEY'S TELEGRAPH WORKS COMPANY.—This company has been awarded a bronze medal by the International Health Exhibition for their electric light cables. We have been given to understand that not a single fault has occurred in any of the cables during the whole time of the Exhibition.

ELECTRICITY AND THE FRENCH NAVY.—Lectures on electricity are given to officers of the French Navy twice a week at the Paris Observatory, where next year's Electrical Exhibition is to be held, under the auspices of the Société Internationale des Electricians, entries to which close on the 25th instant.

BOOKS RECEIVED.—"Magneto and Dynamo Machines," translated from the German of Glaser de Cew by F. Krohn, and specially edited, with additions, by Paget Higgs, LL.D., D.Sc. Symons and Co., 27, Bouverie-street, E.C.—"Electricity, Magnetism, and Electric Telegraphy," by Thomas D. Lockwood. D. Van Nostrand, New York.

THE TELEPHONE IN PORTUGAL.—According to *La Lumière Electrique*, the King of Portugal has placed the telegraph lines of his kingdom at the disposal of Herr Cornelius Herz, for experiments in long-distance telephoning, to be carried out with the co-operation of M. Marcel Deprez, who in France is identified with the electrical transmission of power.

FRENCH EDISON COMPANY.—The Société Electrique Edison has lately supplied 25 lamps to M. Francillon's dye-works at Puteaux, near Paris; 25 lamps to M. André's Tour-du-Pin works at Lyons; 100 lamps to M. Petit's spinning mill at Pont-Audemar; 40 lamps to M. Chatelard's lace factory at Tarare; and 500 lamps to the spinning mill of M. Droulers-Vernier at Lille.

OVERHEAD WIRES.—On Tuesday last Sir Charles Dilke authorised a statement to be made in his name to the Chelsea Vestry, of which he is a member, to the effect that the Local Government Board were pledged to move for a committee on the subject of overhead wires, and it was hoped that, on the report of that committee, a Bill would be brought in by the Government early next Session.

SMITHFIELD CATTLE SHOW.—This annual show was held during the past week in what is to be henceforth known as the "Royal" Agricultural Hall. It is a pity that the company did not celebrate the bestowal of such a title by illuminating the building in a right royal manner, and supersede the old rings of gas jets, which must exert a deleterious influence on the poor beasts during the last week of their existence.

PHOTOS OF ELECTRIC SPARKS.—At the last meeting of the French Academy of Science M. Jamin submitted to the members some photographs of electric sparks obtained by M. Ducretet directly, without object, by the passage of the spark on the sensitised film of the glass. At the same meeting M. Bochefontaine sent a note through M. Richet recalling his experiments on the diffusion of electric currents in the tissues of animals.

TELEGRAPH COMMUNICATION WITH WEST AFRICA.—The India Rubber, Gutta Percha, and Telegraph Works Company have received a telegram from their engineer, Mr. Robert Kaye Gray, announcing the completion of the Spanish National Telegraph Company's cable between Teneriffe and the French West African colony, Senegal, by which the latter is put into communication with Europe through the same company's existing cable from Cadiz to Teneriffe.

THE VAN RYSSELBERGHE SYSTEM.—With regard to this system of simultaneous telegraphy and telephony, the *Bulletin* of the Société Belge d'Electriciens remarks that it does not depend on the use of special microphones or telephones, as in the early experiments. Nor is it any longer necessary to amplify the telephonic voice so as to overcome the noises due to telegraph induction; on the contrary, this induction is annihilated by the graduation of the telegraph currents.

ELECTRICAL STANDARDS.—Mr. R. T. Glazebrook has had occasion to compare with ten standard B.A. units a coil which had been tested by Lord Rayleigh in 1882, the coil then being two years old. He found that its resistance was 9·98335 B.A.U. at 14°·05 C., while Lord Raylelgh found the value 9·98330 B.A.U. Thus, either the coil and the standards have changed by exactly the same amount, which is improbable, for they are wires of different thickness, or they have all remained permanent.—*Mechanical World.*

MODEL OF TRAIN WORKING.—A model has been exhibited at Berlin showing, on a small scale, all the trains running on a railway system. The object is to prevent collisions by having constant intelligence of the relative positions of the trains. The lines are shown on a plate of dull glass, the stations being numbered. Small arrows, representing the trains, are moved, by means of electric current and brushes on the engines making contact with zinc bands along the rails, exactly in ratio to the real progress of the trains.

TELEGRAPHIC COMMUNICATION WITH WEST AFRICA.—Mr. Wm. J. Tyler, secretary of the India Rubber, Gutta Percha, and Telegraph Works Company, 106, Cannon-street, E.C., received on Monday last a telegram from their engineer, Mr. Robert Kaye Gray, announcing the completion of the Spanish National Telegraph Company's cable between Teneriffe and the French West African colony Senegal, by which the latter is put into communication with Europe through the same company's existing cable from Cadiz to Teneriffe.

NIGHT SIGNALS IN THE FRENCH NAVY.—In a paper on this subject, read before the Société Internationale d'Electriciens, M. A. de Meritens described apparatus suitable for giving these signals electrically, and quoted the following sentence from the report of the committee on the subject, after 20 minutes of experimenting:—"This system of signalling must introduce such a change into naval tactics, that it is desirable that all the vessels should be provided with it."

ELECTRICAL TRANSMISSION OF POWER.—In a paper on this subject, by M. Hillairet, printed in the *Bulletin* of the Société Internationale d'Electriciens, he describes how an apparatus may be combined which will give immediately a true diagram of the dynamo employed. Such an apparatus would unite

Digitized by Google

the organs of a registering dynamometer with those of a tacheometer, the motions of which organs would give the variations of speed in *abscissæ* and the variations of moment in ordinates.

ELECTRO-CHEMICAL EQUIVALENTS.—In a note to the Académie des Sciences, Dr. Thommasi proposes to complete the tables of electro-chemical equivalents by an indication of the *calories*, or heat units, of combination, expressed in volts, of each compound. In this manner, it will be known, for instance, that for an amp-hour to be able to decompose 2·98 grammes of sulphate of copper or 3·02 grammes of sulphate of zinc, and so on, the current must have an E.M.F. at least equal to 1·4 volt for the former and 2·46 volt for the latter.

THE EASTERN TELEGRAPH COMPANY.—This company announces the payment, on 15th January next, of a dividend of 3s. per share on the preference shares of the company, less income-tax for the quarter ending 31st instant; and that an interim dividend of 2s. 6d. per share in respect of profits for the quarter ended the 30th September last, with a bonus of 1s. per share for the half year ending that date, on the ordinary shares of the company, free of income-tax, will also be paid on the same date, making a total dividend for the half year at the rate of 6 per cent. per annum.

CAPACITY OF A CONDENSER.—With reference to a formula by J. J. Thomson as to the capacity of a condenser and the number of vibrations of a diapason, M. Brillouin concludes a note in *L'Electricien* as follows :—"If the E.M.F. of the battery is not independent of its capacity, the equations of the variable condition are dependent upon the law of polarisation of the battery and the phenomena of induction ; the distribution of the quantities of electricity among the different wires no longer follows the same laws, and the problem becomes so complicated as to deprive it of all practical interest."

GROSVENOR GALLERY.—The selection of tenders for the work has been made, and the work commenced. Messrs. Marshall, Sons, and Co., of Gainsborough, have obtained the contract for the engines and boilers ; Messrs. Paterson and Cooper, of Little Britain, the contract for supplying and laying conductors, &c. ; while Messrs. Faraday and Sons, of Berners-street, have obtained the contract for fittings. The two main picture galleries will be lighted by Sun lamps supplied and erected by the Sun Electric Light Company. The whole installation is expected to be completed and at work in the course of three or four months.

INVERSION OF CURRENT BETWEEN DIFFERENT METALS.—In a paper before the Académie des Sciences, Paris, on "An experimental demonstration of the inversion of the electromotive force of iron and copper contact at a high temperature," M. F. E. Le Roux, continuing the investigation of a fact ascertained by the French *savan* Peltier, that the surface of contact of two heterogeneous metals becomes heated or cooled according to the direction of the electric current by which it is traversed, found that, at or about a temperature of 1,000deg. C., a current from copper to iron heated the surface of contact, but cooled it at the ordinary temperature.

LAWS OF FRICTION.—At the meeting of the French Academy of Science, on 17th Nov., M. Marcel Deprez, whose method of transmitting power by electric current is shortly to be put in practice between Creil and Paris, cited an experiment according to which the coefficient of friction, a function of the speed, diminished with great regularity in direct ratio with the speed, insomuch that its value varied as 5 : 1, while the speed fell from 550 to 145 revolutions per minute. From 145 to 120 revolutions per minute it remained practically constant, while it again increased rapidly in proportion as the speed approached zero. The absolute value of this coefficient is 0·025 for a speed of 550, and 0·005 for 145 revolutions per minute.

ELECTRIC LIGHTING AT THE SOCIETY OF ARTS.—Up to the ordinary meeting last week, the current has been obtained from a dynamo worked direct by a gas engine, the fluctuation in the lights being very perceptible. On Tuesday, December 2, the Electrical Power Storage Company received instructions to put in a set of their cells to act as a regulator; and by the next afternoon the cells were at work, supplying the lights in the committee room. During Mr. Preece's lecture on Wednesday evening, December 3, the large hall was lit from the gas engine and dynamo, with the cells on a "shunt." The lights were rendered absolutely steady, and the efficiency of cells used as a regulator in this way was clearly shown.

THE TELEPHONE IN THE NORTH.—At the special meeting of the Lancashire and Cheshire Telephonic Exchange Company, held in Manchester on Wednesday, it was announced that, under the new agreement made with the Post Office authorities, the business would be extended by opening "call" offices in various parts of Manchester and Liverpool and at the railway stations within the district, thus establishing communication between the principal towns of Lancashire, Cheshire, and Yorkshire by means of trunk lines, while offices for domestic subscribers would be opened in several portions of Manchester, Liverpool, and other towns. Arrangements were also being made by which subscribers could receive and despatch telegrams by means of the telephone.

SOUTH FORELAND LIGHT EXPERIMENTS.—The series of experiments at the South Foreland, with a view to determine the relative power of various illuminants, is now concluded ; and the experts employed by the Trinity House authorities are engaged in examining and summing up results. Besides the regular observations of their own *employés*, deputed to note the relative power and quality of the lights at certain times and at various points on the paths marked out for the purpose, an appeal was made to captains of vessels passing the Foreland to record their observations in books furnished to them for that purpose. A notice has now been issued to these captains asking them to forward the books containing their entries to the Trinity House without delay.

ELECTRICAL NOTATION.—At a recent meeting of the Société Internationale des Electriciens, M. Hospitalier read a paper on "Uniformity of Electrical Definitions, Conventions, Notations, and Symbols," at the end of which he moved the following resolution :—"We propose the nomination of a commission of electrical notation, charged with studying the question, and giving our proposition the sanction which seems best in the interest of electrical science." This was seconded by M. G. Cabanellas, and adopted unanimously, the following members being appointed to serve on the committee :—MM. Ed. Becquerel, E.-E. Blavier, Marié-Davy, Tresca, H. Becquerel, G. Cabanellas, J. Carpentier, Gauthier-Villars, E. Hospitalier, Maurice Lévy, G. Lippmann, Félix Lucas, Mercadier, De Méritens, D. Monnier, D. Napoli, Pollard, J. Raynaud, and V. Williot. The first meeting of the Electrical Notation Committee was fixed for the 10th inst.

CATALOGUE.—Messrs. King, Mendham, and Co., of the Western Electrical Works, Bristol, have sent us their new price list of electric and magnetic apparatus as supplied to the University Colleges of Bristol and Nottingham, and also to the Science and Art Department, South Kensington. It includes their improved pattern of the new self-exciting Wimshurst Influence Machine, which consists of two circular discs

Digitized by Google

of glass, rotated in opposite directions by a handle and pulleys below, one band being crossed to produce the requisite contrary motion. Upon each exterior face of the glass discs, strips of brass are fixed, which during a certain part of each revolution exert an influence upon those immediately opposite to them. The electricity is collected from these strips by wire brushes, fixed to forked conductors, whence it passes to two terminal electrodes above the machine. Both positive and negative electricity are collected from the machine, which enables the experimenter to obtain more intense results.

PRIMERS OF ELECTRICITY.—The "Primers of Electricity," by Professor E. J. Houston, now number twenty-five in all, and can be had upon application to the Librarian of the Franklin Institute. Price, 50 cents. Over 70,000 of these primers were sold during the exhibition. The following is a complete list of subjects represented:—

No. 1. Arc Lights.
,, 2. Incandescent Lights.
,, 3. Dynamo-Electric Machines.
,, 4. Voltaic Batteries.
,, 5. Electric Circuits.
,, 6. Effects of an Electric Current.
,, 7. Magnetism.
,, 8. Electro-Magnetism.
,, 9. Electricity produced by Friction.
,, 10. The Telephone.
,, 11. The Microphone.
,, 12. The Storage Battery.
,, 13. The Electric Telegraph.
,, 14. Electro-Metallurgy.
No. 15. Electric Motors.
,, 16. The Transmission of Energy.
,, 17. The Lightning Rod.
,, 18. The Galvanometer.
,, 19. Electric Measurements of Minute Time.
,, 20. Electric Clocks.
,, 21. Synchronous Multiplex Telegraphy.
,, 22. Electric Arc Lamps.
,, 23. The Ruhmkorff Induction Coil.
,, 24. The Jablochkoff Candle.
,, 25. Sources of Electricity.

STANDARDS OF RESISTANCE.—M. J. René-Benoît has constructed some standards, the resistance of which is equal to an ohm within one hundred-thousandth, which were submitted to the French Academy at the meeting of the 17th November. As these standards are too fragile and inconvenient for ordinary use, he has also made a certain number of copies, which give the same resistance in a more manageable form. They consist of columns of mercury, contained in tubes bent back symmetrically several times upon themselves, and dipping at the top into cups of sufficiently large diameter. The cups are connected with the tube by indiarubber rings and remain open, which facilitates adjustment and permits of renewing the mercury when occasion requires. The copies have been adjusted by comparison with the standards, by carefully grinding away the ends of the tube until they give the same resistance as the standards. They have always, like the standards themselves, been filled *in vacuo*.

ELECTRIC LIGHT ON THE G. E. R.—Electric light plant is being put down by Messrs. Heenan and Froude, of Manchester, for lighting railway carriages on the Great Eastern Railway. Seven trains have been running since the 1st October without a hitch. The dynamos are driven by Messrs. Heenan and Froude's high-speed spherical "Tower" engines, engine and dynamos being 3ft. 3in. long over all, by 13in. wide and 2ft. high. They are placed on the locomotive boiler behind the dome, and clear of the side view of the driver, as it occupies a centre position on the boiler. Steam is taken from the dome, and exhausts by the chimney. The dynamo used is that made by R. E. Crompton. The engine, which develops 10 horse-power and makes a thousand revolutions a minute, weighs only 57lb.; and the dynamo, engine and bed complete weigh 3½cwt. The wires and lamps are so arranged as not to prevent oil lamps from being put in at a moment's notice in the event of a train being divided from the main, and run on to a branch line; but the Great Eastern Railway Company contemplates applying the electric light to the whole of its trains.

INTERNATIONAL INVENTIONS EXHIBITION.—The applications for space have now all been examined by sub-committees of the council, and a selection has been made of the most promising. The number of applications has been so great that it has been decided to limit very strictly the admissions in those classes which may be considered to have been fully represented in the Exhibitions of the present and of the past year. The council will therefore be obliged to refuse many valuable exhibits in such classes as those relating to food, clothing, and building construction. It will even be a difficult matter to accommodate those which have been selected, and it is feared that the list will have to be still further reduced. As soon as possible, information will be sent to those who have applied for space; but the enormous number of applications, far in excess of what was expected, have made it impossible to do this up to the present. The Guarantee Fund now amounts to £48,280, a sum considerably in excess of that subscribed for the Health Exhibition, or for the Fisheries, the amount for the former being £26,518, and that for the latter £26,656.—*Journal of the Society of Arts.*

ELECTRIC HAIR AND FLESH BRUSH.—The *Scientific American* illustrates this application of electricity, made by the Harbach Electric Department, and consisting of an ordinary hair brush, with a small battery and induction coil attached to the back. The ebonite cell is held between contact springs at each end, and is provided with a screw plug, which is inserted in one end when the battery is not in use; but when in operation this is replaced by a plug carrying a bar of zinc. The current generated by the battery—the exciting fluid of which is bisulphate of mercury—is led to the induction coil, where the strength may be diminished or increased by a tube that slides in and out of the coil. One wire from the coil leads to a metal plate attached to the back of the handle; and the other leads to a plate in contact with bristles made of a suitable conducting material. When the brush is grasped in the hand, the current passes through the body to that point which is in contact with the bristles. It is said that this appliance may be used as a hair brush to relieve neuralgia, headache, and diseases of the scalp, and may also be applied to the body to alleviate rheumatism, paralysis, gout, &c.

SECRECY IN TELEPHONE MESSAGES.—In order to call one of its subscribers, without troubling the others, the Société Générale des Téléphones has hitherto placed, at each station and also at the central office, dials which work simultaneously when the first current is sent along the line, and show when to ring in order to call any particular subscriber. For this purpose, they work hands which move round circles divided into equal sectors, each of which corresponds with a station; and the call is heard at the station answering to the sector on which the index may rest when the call is made from the central office. This arrangement has the disadvantage of making known at all the stations, by the motion on the dials, that a message is about to be sent along the line, so that third parties may conceive the idea of listening. A recent improvement, due to one of the engineers of the Société Générale des Téléphones, permits of avoiding this difficulty. Instead of there being a dial at each station, one only is placed outside the subscribers' premises; and, in addition to the two wires which generally constitute the secondary circuit, there is a third, so arranged that, when the central office is in communication with one of the stations, this communication is interrupted as soon as a third subscriber takes up his telephone.

DAMAGE TO FIRE-ALARM POSTS.—At the Worship-street Police-court, last week, Henry F. Cross, warehouseman, of Lockhurst-road, Clapton; and Henry Weeks, clerk, of Glen-

Digitized by Google

arm-road, Clapton, were charged with wilfully damaging a fire-alarm post in Church-road, Hackney.—Inspector Hudson saw the prisoners walking away from a fire-alarm post, and observing that the glass face in front of it was broken, he accused the prisoners of having smashed it. Cross said that the glass was broken by accident, and he was willing to pay for the damage done.—Henry Bliss, the officer in charge of the Amhurst-road Fire Brigade Station, Hackney, stated that, since the alarm posts had been erected in the Hackney district, in March, 1882, thirty false alarms had been made by persons who played with the machines. Each false alarm had been the cause of bringing out 30 fire engines, 100 men, and 20 escapes, much inconvenience and waste of time being caused.—Mr. Hannay said that as far as he knew there was no special provision for punishment in these cases, and there was no evidence here that the glass was broken wilfully. He could therefore only order Cross to pay the amount of damage, 4d., and Weeks was dismissed.—It is not amiss, as the *Globe* remarks, that the readiness for an emergency of men and material should be tested; but this is rather a wanton and expensive way of doing it.

Progress of Science.—At the distribution, on the 10th inst., of prizes awarded by the Science and Art Department, at the Harris Institute, Preston, Professor Tyndall passed in review the advance made in scientific knowledge. In the course of his observations, the professor remarked that, coming near to our own time, we had the number 772 expressing the mechanical equivalent of heat, and in the whole range of science there was not a more important number than this, indissolubly associated with the name of James Prescott Joule. Based on Joule's equivalent of heat was the wider principle of the "conservation of energy," which affirmed the agencies of nature to be indestructible while they were mutually convertible. There was no such thing as the creation of energy in the universe, and, if a new form of energy should appear, the principle of conservation affirmed that some other form of energy must have disappeared to produce it. With Joule's equivalent in our hands we might go into the universe and calculate, as Meyer and Thompson had done, how suns might be generated by the collision of planetary masses, or, asking whence came the heat stored up in our wood and coal, reply that it was derived from the sun. We might pass from the vegetable to the animal world, and learn that all the energies of the latter were also derived from the sun. One could not lift the arm, nor use the voice, without bringing into play the law of "conservation of energy."

Internal Resistance of Dynamos.—M. G. Cabanellas lately read a paper before the French Academy, reproduced in the *Comptes Rendus* of 24th November, 1884, on "Dynamo-Electro Machines; experimental confirmations of two reactions in working, and the effective values of the internal resistance and of the induced magnetism." The paper contains a table of the results obtained from data of experiments made by M. Marcel Deprez with an A Gramme machine, with reinforced electros, running at 1,110 revolutions per minute. Decreasing resistances had been intercalated externally, so as to give increasing currents from 2 to 42 amperes inclusive. Formulæ in support of the figures in the table are also given. He adds:—"The numerical table possesses a special proving value, because it results rigorously from the electrical and mechanical measurements, taken by M. Deprez during the working of a dynamo, the electros of which were balanced on knife edges, so as to permit of direct electro-magnetic weighings. There can, therefore, be no doubt as to the values attributed to the *deficits* and the actual electromotive forces. The table confirms the reality of the two important secondary effects already pointed out and measured, viz., the increase of effective internal resistance, represented by a number of ohms or volts, and the increase of the revolving magnetic field with reference to the static field with the same currents. The detailed examination of the fluctuations shows to what point the intervening phenomena are intimately complex; and this is a proof *a posteriori* of the interest there was in considering and bringing into prominence, at the beginning of our investigations, the two dominants which incontestibly characterise the *ensemble* of the multiple reactions, magnetic, electro-dynamic, and electrostatic, some of which we have pointed out, taking good care not to state that the list should be regarded as complete."

Underground Wires in Washington.—In his annual report upon the streets of Washington, says the *Electrical World*, Captain F. V. Greene, of the corps of engineers, United States Army, pays much attention to the successful operation of underground electric wires in Washington. Substantial progress was made during the year, he says, 6·11 miles of line and 285 miles of wire being laid underground. The report says that the standard cables have been in constant use without a fault for telephone, telegraph, and fire alarm purposes for nearly a year. The telephone wires using the Western electric cables have also been in constant use for about six months, and are eminently successful. The Bankers' and Merchants' and Postal wires are also in daily and successful use. "The Western Union Company, which has one-half of all the mileage of overhead wire within the city limits," the report says, "is alone in refusing, or at least in neglecting, to take any steps towards burying its wires, although urged to do so by the Commissioners. All applications for new poles for the telegraph companies, or for removing their pole lines, have been uniformly refused. Their wires are now much interfered with by the growing trees, and in order to get their wires out of the foliage they have resorted to the expedient of splicing the tops of their poles. But the trees will soon overtake them, and this and the rotting of their poles will in a few years compel a settlement of the matter, even if legislation is not obtained requiring the removal of their main pole lines. . . . The close of this year will see about 300 miles of underground wires for telephone, telegraph, and electric light purposes in full and successful operation in this city. It would seem, therefore, that the day had passed for discussing the feasibility of underground wires, and the time has come for compelling the removal of all overhead trunk lines within a reasonable period."

Audi Alteram Partem.—A correspondent writes as follows to the *Scotsman*, under date Edinburgh, December 9th, 1884:—"The telephone companies appear to propose opening places of call where any person off the street may for a trifling payment—a penny is suggested in some cases—ring up any subscriber, and insist on holding a conversation with him. I do not think the subscribers have been consulted about this, and to me it seems so very objectionable that, convenient as the telephone is in some respects, there may be a balance of advantages in favour of ceasing to subscribe. Even as things are, the considerations are not all on one side. Whatever you are engaged in must be interrupted to attend to some one speaking through the telephone, although if he appeared in person he might have no claim to such prompt and exclusive attention. Then there are persons who insist on discussing important matters of business through this medium, which, at the best, involves a hurried and indistinct conversation, and considerable difficulty in the way of

Digitized by Google

a trustworthy record of what has passed. Subscribers have the security at present that none but subscribers can address them in this way, and that these are equally interested in the telephone not becoming a nuisance; but if everybody who has a penny or threepence to spare can insist on being listened to by any of the leading business establishments in a city, we shall only be able to protect ourselves against triflers and intruders by paying less regard to all telephone communications. I hope the project will be reconsidered." It will, no doubt, be necessary ere long to add to "Telephone No. ——" a notice to the effect that between certain hours only will communication be afforded. Prominent members of society will also be obliged, as they appoint a secretary to weed their correspondence, also to appoint a telephonist to sift the verbal communications.

National Telephone Company.—At the second Industrial and Art Exhibition, promoted by the Aberdeen United Trades Council, which was opened in that city on Saturday last, the National Telephone Company exhibited a complete telephone exchange in connection with the Aberdeen Exchange system, and opened an office for the transmission of messages from the public to any subscriber on payment of a small fee. The apparatus includes two standards for carrying wires, with the wires run and in use the same as adopted throughout the city in actual practice, specimens of all the line wire apparatus, such as bolts, swivels, stays, &c., with particulars of the test and strains to which each is submitted. The instruments comprise small switch-boards for connecting subscribers' lines, Bell telephones, Blake transmitters, magneto call bells, switches, automatic fire alarms, Gower-Bell telephones, the original Edison telephone with chalk receiver, Wheatstone testing apparatus, old forms of telephones, "Miller's intermediate switch," for use on switch lines, and a fire alarm call signal for the corners of principal streets. The stand was arranged and fitted up under the supervision of Mr. Jno. D. Miller, the district manager for the company in Aberdeen. Several "call" offices have lately been opened by the National Telephone Company in Aberdeen, where any non-subscriber may hold converse with any subscriber to the Exchange system (within a radius of six miles) on payment of a fee of threepence for three minutes' conversation, and one penny for each additional minute. The company is also prepared to establish branch exchanges in the towns surrounding Aberdeen—Inverurie, Stonehaven, &c.—with connection to the Aberdeen Exchange system. The company has also opened three "call" offices in Leith and Edinburgh, where the public may now hold conversation with any subscriber to the Edinburgh and Leith Telephone Exchange, on the same terms as at Aberdeen.

Electric Light at the Law Courts.—Visitors to the Law Courts during the last few days will doubtless have noticed (and that with pleasure) that our prophecy has been fulfilled, and that the electric light has shone forth before the end of the year. On Monday the lights were kept running until the rising of the judges. As, however, the old oil lamps are still hanging about the building, and as the electric spark, during Monday and Tuesday, has been coming and going at its own free will, without much regard to darkness or daylight, we suppose the running on those days may be considered as experimental only. Bearing in mind the amount of new machinery, belting, and shafting which were set in motion all at once, and the quantity of dust which a daily contemporary so graphically described, it will be evident to our readers that a considerable amount of adjustment was necessary, which could only be effected by practically running the plant. The site of the installation is the vaulted basement beneath the Great Hall, in which also is placed the ventilating and warming apparatus. The electrical plant consists of two single-cylinder Galloway engines, each capable of indicating 110 horse-power, and supplied with steam from two Lancashire boilers. The dynamos are of the Crompton-Bürgin type, self-exciting, and eight in number. One engine and one boiler only are employed in the lighting sevice; the other engine and boiler being in reserve, as is also one of the dynamos. Two machines are employed on the six Crompton arc lights which illuminate the Great Hall, and the other five supply current to the 600 incandescent lamps which light the various courts and corridors. The incandescents, of 20 candle-power each, are arranged in parallel; and, by an adjustment effected at the switch-board, the variation in their requirements is perfectly regulated. The arc lights are of 2,000 actual candle-power each. During the vacation, all the lamps and wires were overhauled and the circuits tested. When all the lights were switched on, on Monday evening, there were only some half a dozen lamps out of the total of over 600 which did not light up. The new Bürgin machines are working splendidly, and so is the engine.

Hammond Electrical College.—The annual *conversazione* of the Hammond Company Electrical Engineering College was held on Wednesday last at the College in Red Lion-square, W.C. The guests were received by the President, Mr. Robert Hammond, and the principal, Mr. Hugh Erat Harrison, B. Sc., many electrical and scientific instruments being explained by them and by Mr. Fred. C. Phillips, the electrical engineer. Although there was a Brush machine for arc lighting, it was not used on this occasion. The rooms were, however, brilliantly lighted by Swan incandescent lamps, with current from an alternate-current Siemens dynamo, excited by a shunt-wound direct-current Siemens machine, both driven by a 6 horse-power Otto gas-engine, capable of working up to 8 or 9 horse-power. In the cellars were thirty-eight 1 horse-power Faure-Sellon-Volckmar storage batteries, of a useful capacity of 100 amp.-hours, coupled in series. They fed 25 ship incandescent lights on the second floor, which shone with remarkable brilliancy, owing to the E.M.F. being rather in excess. On the first floor, Capt. Aylmer, M.P., showed the newest forms of Trouvé's portable lamps, which were illustrated in *The Electrician* a fortnight ago, and formed by no means the least of the evening's attractions. A number of radiant-matter tubes also created considerable interest. A Ferranti ship dynamo was shown in two parts, divided vertically, so that its construction could be examined. A small Victoria A dynamo, made at the Brush works, drove a sewing machine by means of Sir Wm. Thomson's electric motor. In the library, the Electric Apparatus Company had quite an exhibition of new electrical apparatus, including Sir Wm. Thomson's "mouse mill" electric lighter for gas, the sparks from which are produced entirely by friction, there being no battery. All the scientific apparatus belonging to the college was on view; a concert was given by Miss Marianne Fenna, Miss Marian Ellis, Mr. Reginald Groome, and Mr. George Basset, Mr. Thomas Physick presiding at the piano; and altogether a most interesting evening was spent. The membership of the college takes the form of a two years' apprenticeship to Mr. Hammond, the president of the college and managing director of the Hammond Electric Light and Power Supply Company, the course of instruction being arranged with a view to afford a complete theoretical and practical training to those who intend devoting themselves to the electrical engineering profession. Mr. Robert Hammond, who has electrically lighted his house at Highgate, has issued invitations to view the arrangements on Monday next.

THE STEAM ENGINE INDICATOR.—IV.

BY AMICE.

Kraft's indicator, to which we referred in our impression of the 6th inst., is illustrated by the accompanying perspective and sectional engravings (Figs. 11 and 12). As mentioned in our last, this was one of the first indicators made with a very light pencil arm having a free end. The other moving parts were also reduced to the smallest weight. In our engraving (Fig. 11), *a* is the steam cylinder, fitted with a piston, *b*, the piston being, as is usual in these instruments, made steam tight by a very accurate fit, the cylinder being very carefully bored. No rings or means of making the piston tight, except accuracy of workmanship, are ever used for indicator pistons. The upper part of the cylinder is slightly enlarged and closed by the cover *c*, while the lower part is firmly screwed into the tapered end piece *d*, which fits into the upper part of the indicator cock at *e*, where it is held by the hand nut *f*. The upper part of the cylinder

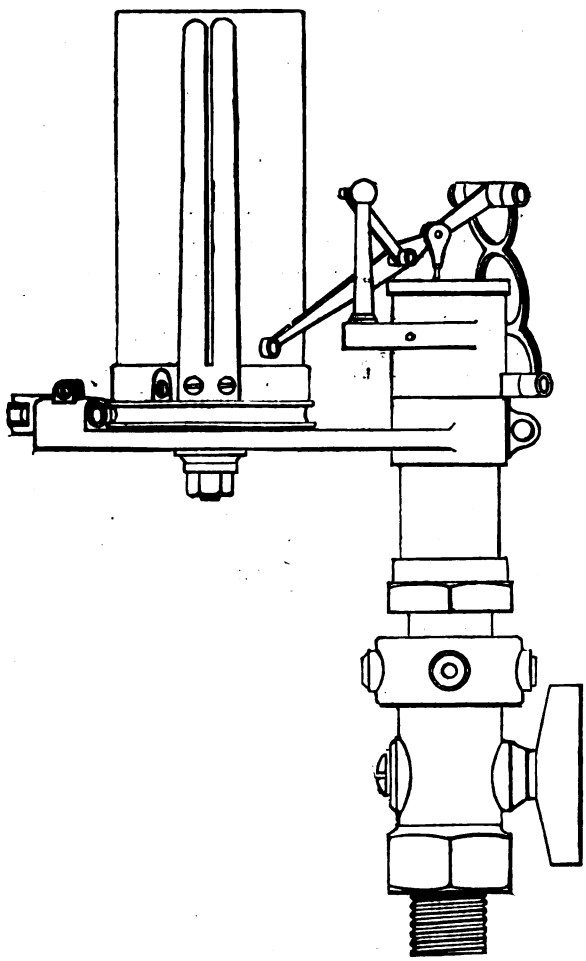

FIG. 11.

is surrounded by a collar, *h*, which carries an ear by which the standard *r* is supported, and a projection to which *q* is articulated, the right line motion of the pencil being obtained by the radius rod and the proportion between its length, the length of *q* and the position of the joints in the pencil arm *p*. To prevent water from sprinkling the diagram paper, as it does when holes for the admission of air above the piston are made in the top cover, they are in this indicator made below the piece *g* which carries the paper drum A. The piston rod *l* is of a trunk form at *m*. The spring, not shown, against the resistance of which the steam raises the piston, is of spiral form, and is provided with a nut at either end, by which it is screwed to the piston at *k* and to the inwardly projecting boss in the under side of the cover *c*. The trunk *m* or tubular part of the piston rod slides through the cover *c*. Within the trunk is the rod *o* jointed to the pencil arm *p*, the lower end of this rod having a ball and socket joint. Our engraving shows the indicator at half size, so that it will be seen that the moving parts are all light. The pencil arm is generally made to carry a metal pencil—for instance, soft brass, to mark on prepared diagram paper. It is, however, also made to take a very hard lead pencil, not only so that ordinary paper may be used, but because some German engineers consider that the friction of a hard lead pencil on glazed paper is less than that of a metal pencil on the prepared paper, known as metallic paper, which is more generally used. There is no doubt that the friction of a metal pencil is greater on the prepared paper than a hard graphite pencil on hard paper, especially when the prepared paper, which is much the more expensive, is in a steamy atmosphere.

The paper drum A moves upon a steel spindle V, screwed into the projection *g* by an ordinary nut. The tube V is loose upon this spindle, and is made in one piece with the pulley *y* and the box *t*, which contains a coiled spring. The piece W is a cover for the spring, and is held in place by the nut X. The drum A is fixed to the pulley *y*, round which is coiled the

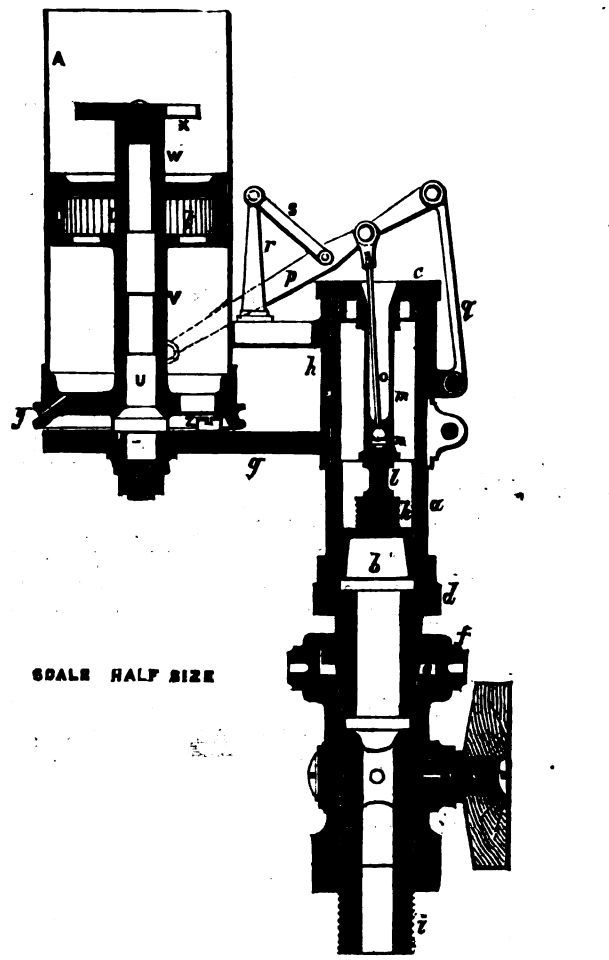

FIG. 12.

string, by which motion is given to the drum from some part of the steam engine. The string is guided to the pulley *y* by a pulley which may be set in any desired direction. The string pulls the drum round through about three-fourths of a revolution against the resistance of the spring at *t*, which forces it back as the string returns.

The plug of the cock to which the indicator is attached is drilled with holes in two directions, so that, as shown, steam may pass from the engine cylinder to the indicator piston, or by turning the cock in one direction steam may be allowed to blow through to the air from the pipe below the indicator, so that any water in the pipe connections may be blown away. If water is in these connections, especially if they are of any length, it will give to the diagram an irregular form, not representative of any action of the steam in the engine cylinder.

The piston springs constitute one of the most important parts of an indicator, and with these generally we shall deal specially when we have given the reader some further particu-

Digitized by Google

lars of the indicators most in favour. The next in order is the indicator invented by Mr. E. T. Darke, and which is illustrated by Figs. 13, 14, 15, 16, and 17. One of the most important features in this is the pencil motion, which consists of one steel arm pivotted at one end by

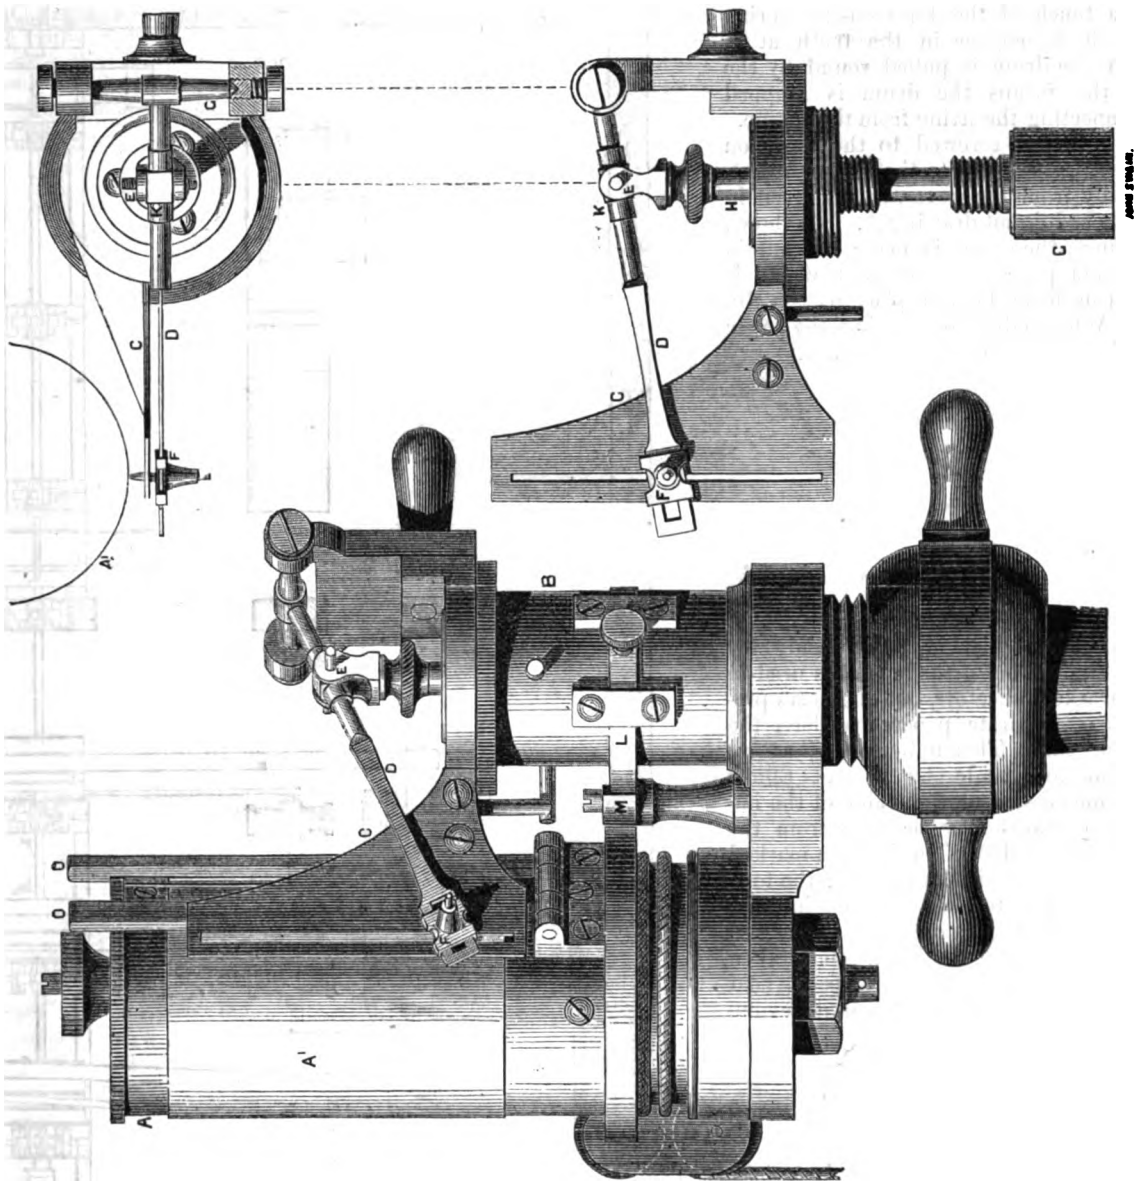

Fig. 15. Fig. 16. Fig. 13.

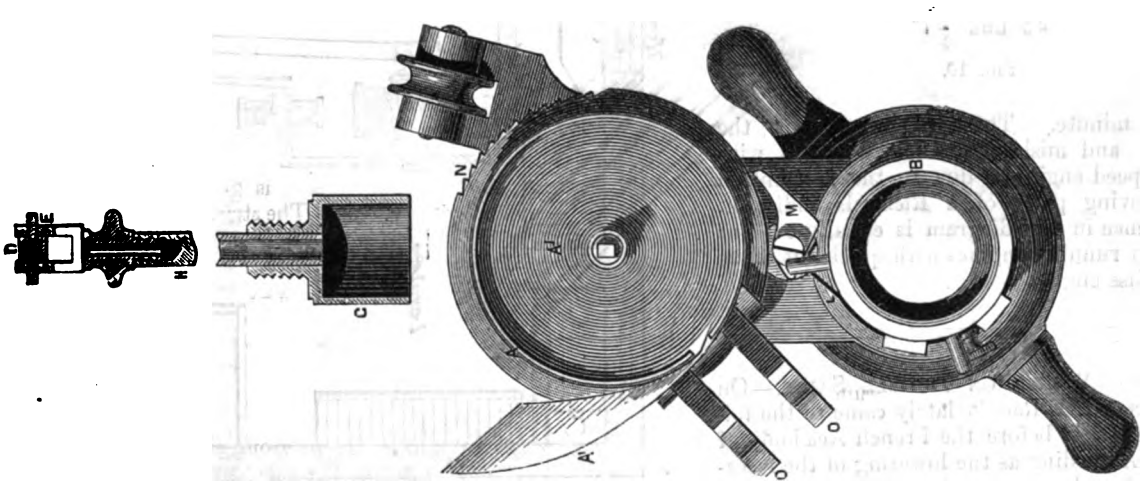

Fig. 17. Fig. 14.

centre points on the two ends of a T head, and carrying at the other a sliding piece, F, which is provided with a holder for a metallic pencil. The pencil is kept in a straight line parallel with the axis of the paper drum by being made to pass through a slot guide in a plate, C. The piston-rod head carries a jaw, E, and in this is a sleeve, K (Figs. 15, 16), which is an accurate but easy fit on the pencil arm, which is made round at this part. With the motion of the piston and the jaw E, the sleeve K is caused to slide through a small range on the pencil arm as the latter describes an arc on its pivots. The end of the pencil arm, also, in a similar way slides in the piece F, which is compelled by the slot to keep the straight line of the slot. Our engraving shows the indicator full size. The piston rod is hollow, see Fig. 17, the piston is made smaller and of shorter stroke than in the Richards,

Digitized by Google

and there are differences in the springs and also in the construction of the jaw head seen in Fig. 17, which we need not describe, as the forms adopted are so well shown in our engravings. In Figs. 13 and 14, Darke's detent gear, which we described in our last impression, is seen at M L, the pawl M being out of gear in Fig. 14, but a touch of the knob on the spring L will cause it to engage in the teeth at N (Fig. 14) when the drum is pulled round by the string. By this means the drum is stopped without disconnecting the string from the engine.

The piston spring is screwed to the screw on the piston G (Fig. 16), and to the screw projecting downwardly from the cover, as also seen in the same detached detail drawing A. As shown in our engravings, the drum is made to contain a roll of diagram paper, A', that part which is outside the drum being held in place by the clip springs O O. When a diagram is taken the paper containing it is torn off, the removal in this way

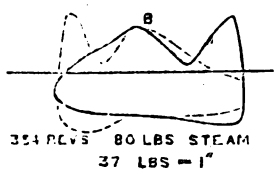

Fig. 18.

bringing forward and placing paper ready for the next diagram. This arrangement is used in most of the Darke indicators, but engineers preferring to put on separate papers may have the drum fitted for this. This indicator is, as we previously remarked, made by Messrs. Elliott Brothers, Charing-cross, and the value of the improvements it contains may be seen from the diagrams (Figs. 18 and 19). The diagram marked B is taken by a Richards indicator from the low-pressure cylinder of a torpedo boat engine, and that marked A from engines of similar construction working under similar conditions, but taken with a Darke's indicator. The torpedo boat engines were running at several hundred revolu-

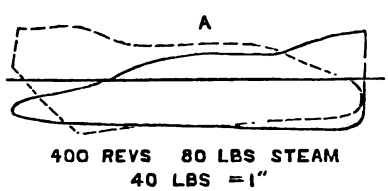

Fig. 19.

tions per minute. These diagrams show the very great and misleading effect obtained with the high speed engine as due to the momentum of the moving parts of a Richards indicator. The difference in the diagram is equally evident from slower running engines with quick cut off as in the Corliss engine.

Action of Water on Double Salts.—On this subject, F. M. Raoult lately came to the following conclusion before the French Academy of Science:—According as the lowering of the freezing point of a double salt, dissolved in water, is equal or inferior to the sum of the partial lowering of the freezing points of the simple salts composing it, it may be affirmed thatthe double salt is or is not entirely separated into its two generators.

VICTORIA INSTALLATION.

Our illustrations on this and the following page show, first, the arrangement of shafting and dynamos on the first floor; secondly, a section of the floors, showing position of boiler, engine, dynamos, &c.

ELECTRICITY IN EAST JAVA.

At the beginning of the present year Messrs. Zwieten and Co., of Malang, installed the electric light in the palace and gardens of Sultan H. B. VII., of Djokjakarta, with 200 Swan incandescent lamps (including four in engine room), and four 500-candle Siemens arc lamps, with Siemens dynamos, driven by a 30 horse-power Davy-Paxman engine, with multitubular boiler. After eight months' working the contractor has received a satisfactory testimonial of the results, notwithstanding the fact that the driving and superintendence was left to Java workmen.

In March last the same firm fitted the palace and gardens of Prince Prang Wedono, of Socrakarta, with electric light plant, consisting of five 500-candle Siemens arc lamps, and sixty 20-candle Swan lamps, with Siemens dynamo, driven by a 12 horse-power portable engine. The working of this plant gives every satisfaction; and it is stated that the common teak wood used here as fuel gives no trouble in raising or keeping steam for driving, it being used in portable engines constructed for coal burning.

The Socrabaja-Selosedjo sugar house was next fitted with 500-candle Siemens arc lights (one outside and four inside), and also 20-candle Swan lamps. The firm is now engaged in putting down a large plant, also for Prince Prang Wedono, at Socrakarta, with six arc lights and a hundred Swan lamps.

In sugar houses, the delicate mechanism of the Siemens lamps gives some trouble, owing to steam and dirt. Our correspondent states that next crushing season it is intended to try the Boston 60-candle lamps, some orders being already received; but the prices of sugar, regulated by law, are somewhat of a drawback to progress. As regards electrical transport, there will be much to do in small electric railways before long; and it is thought that a form of telpherage lines was specially invented for coffee planters' use.

In electric lighting there is, of course, a large field in Java, as gas costs 13s. 3d. per thousand cubic feet. This high price would not be maintained but for the slowness of the inhabitants to appreciate the advantages of electric light applied to houses. The monopoly of the gas company would soon be at an end if house-to-house lighting were carried out by means of small caloric engines, or, possibly, primary batteries, as the long distances, added to the great expense for wire, would be against the establishment of central stations.

EXPERTS ON THE ELECTRIC LIGHTING ACT.

A company of gentlemen calling themselves the "Dynamicables," have, we are informed, met together from time to time to discuss the fortunes and prospects of electric lighting. We may conjecture that the hopes which were nipped in the bud by the winter of 1882 have been trying to survive, if not exactly to bloom, in the more congenial atmosphere of convivial foregathering. Be this as it may, they have established themselves firmly as an authority on the practical and scientific bearings of electric lighting, and by mutual conference and discussion have arrived at clear views with regard to the business in which they are all directly or indirectly interested. The latest result of their deliberations has been the formation of a representative committee, who have drawn up a report on the Electric Lighting Act, embracing the views of the whole body. As might be expected from a company sufficiently good-humoured to discuss their differences round the social board, and sufficiently humorous to style themselves after the manner of the late Mr. Byron, their report is neither violent in its tone nor ridiculous in its conclusions. It does not sin on the side of being too exacting, nor is there any trace of that Philistinism which commonly disfigures such documents by failing to see the funny side of unreasonable pretensions. It is, in short, a plain business-like Report of considerable argumentative merit; and as it is put forward on the authority of the foremost men in the sphere of electric lighting enterprise, both theoretical and practical, it demands and deserves the highest consideration. It has yet to be discussed, we are told, by the whole band of Dynamicables; but except for the light thrown upon the subject by Mr. Chamberlain's recent declarations, no material modification is likely to be made in the Report.

The form of License granted by the Board of Trade for the lighting of Colchester, and the form of Provisional Order adopted by the Board in 1883, have enabled the Committee to see exactly the interpretation put upon the Act by the Board itself. This interpretation the Committee accept as decisive, although on the subject of licenses they think that a different rendering might have been permissible. Facing the situation, therefore, created by the authorities at the Board of Trade, the Committee set themselves to prove that the Act is unworkable as at present administered; secondly, that a few verbal alterations only would be needed to make it workable; and, lastly, that the required alterations are reasonable, just, and indispensable.

As regards the first-named contention, their task is perfectly easy. Events have settled that point for them—or, perhaps we should say, the absence of events, for the Act has literally destroyed what it ostensibly professed to promote. But the Committee have introduced some fresh argumentative matter into the discussion well worthy the consideration of the public as well as of the Board of Trade. It is pointed out that the Gas Companies hold their powers in perpetuity, and can afford to work at greatly diminished profits, which the law allows to be made up in after years by enhanced prices and increased returns. To compete with gas, therefore, any other system of lighting cannot hope to succeed if handicapped by conditions less favourable than those enjoyed by the existing system. In order to make its term of twenty-one years' existence at all remunerative the electric light would have to be charged for, not at a rate comparable with that of gas, but at a luxurious rate, the effect of which would be a restricted demand for it and attenuated profits. To get a fair commercial return within twenty-one years prices would have to be very high—so high as to prevent would-be consumers employing the electric light, and thus ensuring its failure at the very outset of its career.

If, however, the undertakers by low prices create an enlarged demand for their illuminant, they will invite their own ruin by attracting the cupidity of the Local Authorities, who are empowered to step in and buy up the concern. But we are wrong. They do not buy the "concern" in the business meaning of the term; they can force the sale of the plant at its then value, and appropriate the "concern" for nothing. This is a sort of bargain a parallel to which it would be difficult to find in the whole range of commercial experience. A near approach to it would be the compulsory sale of beer-barrels and bottles to the Blue Ribbonists, with no compensation for the publicans' "good will." To make the resemblance complete the buyers would have to step to the other side of the counter, doff their blue ribbons, and carry on the business on their own account. That very small profits even would tempt the Local Authorities to force the undertakers to part with their business is evident when we remember that money may be borrowed for local objects at 4 per cent. By availing themselves of the provisions of the Act they could thus do a good stroke for the ratepayers. The seven years' grace allowed in the event of escaping at the twenty-one does not mend matters in the least; if the undertaking has not become profitable in the longer period its efforts to recoup itself will be paralysed by the certainty of confiscation at the expiration of another seven years.

It was a parochial mind that framed this section, and it should be met by a firm resistance on the part of men who have business minds. Granting, for the sake of argument,

Digitized by Google

that the monopoly of Gas and Water companies has worked badly—though we by no means admit the assertion—the terms of compulsory sale, if a transfer is really necessary to prevent such monopoly, should be on a liberal basis; and the Committee of the Dynamicables are, we consider, very moderate in demanding a fair value for the undertaking *considered as a going concern*, a vastly different affair to selling its plant at a valuation. The only other acceptable alternative is a considerable extension of the working period. The Committee do not name an alternative to the twenty-one years fixed by Section 27, probably because it is impossible to make the calculation. It ought to be left for the next generation to determine.

Some modification in the conditions on which light is to be distributed under the Act is also asked for by the Committee. Gas companies, wherever they have supplied their customers without meter, have rightly been allowed to insist on the use of certain burners. The electric lighting undertakers, on the contrary, are required to permit the use of any lamps the users may choose—or, in other words, may consume the commodity as wastefully as they please. Mr. Preece tells us that the Edison meter answers well in New York and registers within about two per cent. But neither the Edison nor any known meter has yet been sufficiently well established to warrant a new undertaking supplying electricity in any other way than by hours, regulated by the lamps provided or approved by themselves. Clause 16 ought to be amended in this sense.

Further, the form of Provisional Order compels the laying down of mains, and additions to them, in such an arbitrary way, that the public have all the advantage and the undertaking all the risks. If the supply is to be compulsory, the price should be regulated by the quantity supplied. An intermittent demand should be met by proportionately high rates for the exceptional convenience and outlay. Lastly, as to licenses, the committee are of opinion that Section 3 of the Act has been erroneously interpreted; and that if the undertakers of limited schemes covered by Licenses are to incur obligations towards the public similar to those imposed in the case of Provisional Orders, legislation as to Licenses will, like all the rest of the Act, remain a dead letter.

CORRESPONDENCE.

PAYING FOR SPECIFICATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I observe in your issue of the 6th inst. a letter, signed "Engineer," accusing Messrs. Mackenzie and Brougham of making improper charges for specifications issued by them on my behalf for work to be done at the Grosvenor Gallery, in *re* electric lighting.

Messrs. Mackenzie and Brougham had my instructions to issue separate specifications and forms of tender for each branch of the work, and not to deal with it as a whole.

I also instructed them to divide the expense of preparing the specifications between me and those who should apply for them, my object being to lessen my own expense, and to limit the competition to those who acted with a *bonâ fide* intention of dealing with the matter.

Please insert this letter in your next issue.—Yours, &c.,

COUTTS LINDSAY.

11, Grosvenor-square, Dec. 9.

[We beg most emphatically to protest against this statement. Our correspondent did not accuse Messrs. Mackenzie and Brougham of making improper charges. Our correspondent's words are, "are asking, under the powers vested in them by the Grosvenor Gallery proprietors, &c." Sir Coutts Lindsay states that the charge was made according to his instructions, and we, in the interests of electric lighting, protest against such instructions in the strongest possible manner. The action of Sir Coutts Lindsay has been this, that almost every company and firm of repute has refused to tender, or has withdrawn its tender, a fact which furnishes a complete justification of our correspondent's remarks.—ED. *E.*]

To the Proprietor and Editor of *The Electrician*,
1, Salisbury-court, Fleet-street.

GENTLEMEN: We have been consulted by Messrs. Mackenzie and Brougham, of 15, Great George-street, with reference to a libel published by you on page 73 of the number of *The Electrician* issued on the 6th December, under the heading "Paying for Specifications."

In that letter you impute to them dishonest and improper practices; and as they have already applied to you for the name of the writer of that letter, which has not been furnished, we are instructed to inform you that unless an ample retraction and apology, to be settled by us, be published, together with payment of costs occasioned by the libel, we are to commence an action against you.—We are, yours obediently,

LEWIS AND LEWIS.

10 and 11, Ely-place, Holborn, London, E.C.
Dec. 10, 1884.

[Once again, it seems, in our endeavours to protect the true interests of electric lighting we are threatened with a libel suit. Our answer to Messrs. Lewis and Lewis, in this case, is furnished by Sir Coutts Lindsay's own letter above, and our remarks upon it. The statement that "dishonest" practices were imputed to Messrs. Lewis' clients is wholly unfounded. That is all we have to say.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "To be or not to be" (paid for)? "that is the question." Of course, no one will doubt the propriety of paying the consulting electricians for their work in getting out forms of stipulations, fines, &c., as people naturally expect to get paid for this kind of thing; but who is to pay them? One would think that those who engaged them and so received the benefit of their services would be willing to pay for the protection afforded; but still, when I think of that very interesting tale of the monkey and the cats I am fain to learn a lesson from it. The monkey, as you will no doubt remember, had a nibble *both ends* of the cheese, and what the cats got for their share was the rind, plus the trouble of getting it.

Another instance just occurs to me of a plan adopted by unprincipled surveyors of getting paid at a cheap rate to their employers, and no doubt if the case under consideration is allowed to pass unchallenged the same may be enacted in a more scientific branch of business. I refer to the position of the builder who, before he obtains an advance, is obliged to agree to a large percentage being paid to the surveyor, otherwise no certificate is forthcoming.

These are extreme cases of extortion, but they have small beginnings, and surely electric lighting is not coming to this. A contractor, after he has spent some ten or twenty pounds in getting out a tender and specification, with suitable tracings, ought certainly not to be mulcted in a payment of £3 for the schedule of restrictions, &c.

It is a well-known fact that however well the consulting engineers do their work, new specifications, designs, &c., have to be got out by the contractors for their particular class of machinery.

Could not some plan be devised by which the successful tenderers should pay an amount approximately equal to that which would be lost by returning the £3 each to those who are unsuccessful?

As the case in question appears to be the first of its kind in the electrical world, where the money paid for specifications is not returnable, the matter ought to be met at the outset, and united action on the part of the leading companies taken. If, then, an attempt at extortion be made in the future, it will be

Digitized by Google

well known that should any tenders be received they will be from none but second-rate contractors and treated accordingly.
—Yours, &c., JONATHAN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent "Engineer" in your last issue calls attention to the conduct of certain consulting engineers who, under the powers invested in them by the Grosvenor Gallery proprietors, asked three guineas for their specifications, and which sum is not returnable. Now, without endorsing the language of your correspondent, which I think is unnecessarily harsh (as, from my personal knowledge of the gentlemen referred to, I am certain that they had no such intention as he imputes to them), still, as you, sir, call for some expression of opinion on the subject, I take this opportunity of protesting against the proceeding. I think most engineers will back me up when I state that such fees for specifications are *always returnable* on receipt of a *bonâ fide* tender.

Electric light engineering is work of such a tentative class that all of us engaged in the trade are compelled to maintain an expensive staff of engineers and draughtsmen solely for the purpose of preparing a vast number of schemes, each consisting of reports, specifications, drawings, and estimates, the greater portion of which do not come to fruition solely because of the public belief that by waiting a "bit longer" some great and startling improvements will crop up which will enormously reduce the first cost of the plant.

As the cost of this estimating staff must eventually come out of the pockets of those who *do* purchase electric lighting plant, it is most undesirable in the interests of the public that it should be further increased in any way.

I addressed a circular letter to the trade on this subject, and I may say that in every instance save one I received replies agreeing with what I have above stated, the one exception being of course from the firm who was successful in obtaining the order.—Yours, &c., R. E. CROMPTON.

Mansion House-buildings, London, E.C.,
Dec. 11, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We fully endorse "Engineer's" opinion as expressed in last week's issue, and we think the fees should at least have been returned when the tenders were sent in, as is usual in most cases where a charge is made for a specification.

We can only hope that the Grosvenor Gallery proprietors will accept one of the tenders, so that some member of the profession will have the benefit, and that the trouble which many firms have taken will not be entirely lost.—Yours, &c.

OPPERMANN BROTHERS.

London and Chicago, Dec. 6, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We object to payment for the specifications referred to—not only because the attempted innovation is quite unsuited to the present position of the electric lighting business, but also because in the case of the Grosvenor Gallery the specifications were for part only of the electric lighting plant, the companies tendering having no voice in the selection of the dynamo machines to be employed. Furthermore the engineers informed me that the dynamo machines they intended to use would not be capable of charging storage batteries, for which no provision was made.

I think that electric lighting companies in tendering for any important work should be able to tender for a complete installation. It is all very well for the engineers who prepare specifications to assume all the responsibility; but, if the lighting be unsuccessful, depend upon it that the parties whose reputation is really at stake in the eyes of the public are those whose lamps go out, whatever the cause may be.—Yours, &c.,

GEO. OFFOR,
Manager of the Consolidated Electric Company (Limited).

67A, and 68A, Cow Cross-street, December 10th, 1884.

THE GULCHER ELECTRIC LIGHT COMPANY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your report in yesterday's *Electrician* of the meeting of the Gülcher Electric Light and Power Company (Limited) (the accuracy of which I do not question) states that "misrepresentation" has been applied to me with regard to transactions I have had with the company.

As the case is *sub judice*, I cannot ask you to allow me through your columns to vindicate myself, but as my silence under such an accusation may be open to misconstruction, I would ask you to permit me to say that I am advised that I have a most complete answer to the case which the company sets up against me, and that the chairman of the company, in his speech to the shareholders, forgot or omitted to mention (probably owing to his recent connection with the company) the sacrifices I have from time to time made in their interests, and the confirmation over and over again by the company of my past dealings with them, of which dealings they now for the first time complain.—Yours, &c., WILLIAM CROOKES.

London, Dec. 6, 1884.

ILLEGAL PRACTICES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We find that certain people have been making incandescent lamps, looking externally like ours, with the exception that the finish is not so good, and have been selling them as ours at a low price.

We should be much obliged if you would notice this in your next issue, calling attention to the fact, as, of course, it is doing us much damage, besides being unnecessarily disappointing to the purchasers of the lamps.—Yours, &c.,

WOODHOUSE AND RAWSON.

11, Queen Victoria-street, London, Nov. 28th.

ELECTRIC LIGHTING IN AMERICA.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The report of the meeting of the Society of Arts upon this subject must have aroused a feeling of shame and indignation in the minds of all your readers who are interested in electric light—shame, that as a nation we should be so far behind America in what is now admitted on all hands to be the most conspicuous improvement and advantage which modern ingenuity has devised; and indignation, that this result should have been brought about by the passing of an ill-digested Act of Parliament in a period of panic.

The public are now weary of the oft-repeated tale, which has been told *usque ad nauseam*, that "the whole thing was premature;" that "an attempt was being made to create another monopoly;" that "promoters had made large sums of money;" that "the object in view was the sale of worthless patents rather than the establishment of a valuable industry," &c. Be it so. But this fact remains, and cannot be gainsaid, that until the Electric Lighting Act be repealed or materially altered no rational men will now embark their money, nor will any honest and prudent Board of Directors lay out the money of their shareholders in electric lighting enterprises in this country.

In the neighbourhood where I live (Marylebone) the streets are simply unsafe after dusk on account of the feeble light from the gas lamps, except on moonlight evenings. At other times a torch or bull's eye lantern is almost a necessity in crossing the streets.

I am only one of tens of thousands in London who would gladly pay anything within reason to have the electric light inside, as well as outside, their houses. Gas is so injurious to health, and so detrimental to furniture, ceilings, pictures, &c., that I have resorted to the use of oil lamps and candles almost throughout my house.

Before Mr. Chamberlain's Act was passed I made two or three efforts to get the electric light introduced into the neighbourhood where I reside, and should probably have succeeded; but before I could bring these efforts to a successful issue the Act was passed, and the company with whom I was in treaty

Digitized by Google

and I myself saw that they were hopeless, and I abandoned them.

Is the foolish fear of a monopoly to stand any longer in the way of the successful prosecution of a discovery which is so beneficial to health, so preservative of property, and last, but not least, so conducive to public safety that the Chief of Police in New York has gone so far as to say that "every electric light erected means a policeman removed"?—Yours, &c.,

December 10, 1884. R. B.

[Owing to pressure on our space, we are compelled to leave over till our next issue letters from Mr. W. B. Esson and "Zero."]

THE ALTERNATE-CURRENT MACHINE AS A MOTOR.*

BY PROFESSOR W. GRYLLS ADAMS, F.R.S., PRESIDENT.

(CONCLUDED FROM PAGE 76.)

On November 10th, I again made further experiments with the three De Meritens magneto machines, and made measurements of the light given by the arc worked from the machines separately and combined in parallel circuit.

The resistance of the leads from the engine room to the photometric gallery in which the measurements were made was ·032 ohm (cold) and the leads were heated considerably, and where exposed became quite warm to the touch when carrying the current from two machines or from the three machines.

One machine alone gave a current of 175 amperes, with an electromotive force of 40 volts at the machine terminals, and an electromotive force of 33 volts at the extremities of the arc, giving 5,775 watts expended in the arc and 1,225 watts expended on the leads.

Two machines worked well together, being driven independently, and gave an average current of about 275 amperes, with an electromotive force of 47·5 volts at the machine terminals, and an electromotive force of 35·5 volts at the extremities of the arc, giving 9,750 watts expended in the arc and 3,300 watts expended on the leads.

Another experiment with two machines gave an average current of 278 amperes, with an electromotive force of 48 volts at the machine terminals, and an electromotive force of 36 volts at the extremities of the arc, giving 10,000 watts as the energy per second expended in the arc.

These experiments give for

(1) One machine—
7,000 watts (electrical energy in external circuit);
1,715 watts (electrical energy in internal circuit):
giving 8,715 watts as the total electrical energy per second.

The power absorbed, as shown by indicator diagrams, during this running was 13·8 horse-power, or 10,295 watts, giving an electrical efficiency of 84 per cent.

(2) Two machines—
13,300 watts in the external circuit;
1,800 watts in internal heating of coils;
giving 15,130 watts as the total electrical energy per second.

The power absorbed was 28·53 horse-power, or 21,280 watts, giving an electrical efficiency of 71 per cent.

The electromotive force and current remained as steady as when the two machines had been mechanically connected together by clutches, completely proving that with equal machines such mechanical connections are entirely unnecessary.

This we had also found to be the case in the experiments of October 18th, when experimenting with two machines, and also with the three machines running on the same parallel circuit. The third machine has no mechanical connection with the other two machines, except through the belting, being driven from the same countershaft. When run together, the three machines gave a steady current of 300 amperes through an arc with an electromotive force of 49 volts at the machine terminals, and of 37 volts at the extremities of the arc, giving 11,100 watts expended in the arc.

On account of the high resistance and consequent heating of parts of the lamp, and the irregularity of burning of the 40 millimetre carbons employed, the current from the three machines was only about 25 to 30 amperes greater than the current from the two machines.

The heating of the lamps was, however, greatly diminished by means of a by-pass, suggested by Dr. Hopkinson, from the conducting leads to the lower carbon, whereby a very considerable portion of the current was shunted past the lamp.

In the experiments on November 10th, with the three machines driven independently in parallel circuit, there was considerable variation in the mean electromotive force and in the mean current. The irregularity was due to the very unequal burning of the carbons, which was noticed at the time of the experiments, and not to any irregularity in the working of the three machines; for as the electromotive force increased the current diminished, and there was comparatively little variation in the rate of work done in the arc. In one set of experiments the electromotive force varied from 42 to 32 volts, and the current from 270 to 310 amperes, yet the product remained much more nearly constant, and the average was about 11,000 watts. In another set the electromotive force varied from 41 to 37 volts, and the current from 290 to 316 amperes, giving an average of 11,600 watts in the arc.

The belt was now thrown off the third machine, which still continued at the same uniform speed, being driven as a motor by the current from the other two machines, with the arc still in the external circuit. Thus, of three alternate-current machines arranged in parallel circuit to supply current to an external circuit, one may be run as a motor by the current from the other two, which will continue to supply an arc in the external circuit. The electromotive force at the extremities of the arc and the current through the arc were measured, and experienced wider variations than in the last experiment with three machines parallel, but the power in the arc remained very constant at about 12,000 watts, rather greater than when the three machines were driven directly from the engine. The arc also was observed to be steadier when the third machine was being driven as a motor, as though the motor acted as a governor on the circuit. The electromotive force at the extremities of the arc varied from 52 to 41 volts, with occasional readings outside these limits, and the current varied from 240 to 285 amperes, the electromotive force rising when the current diminished in such a way that the product remained very nearly constant. It would seem from these experiments that the work done in the arc with two machines combined in parallel circuit, without the third machine in the circuit at all, was considerably less than the work done when the two machines were supplying the arc, and at the same time driving the third machine as a motor.

Not only so, but when the machines were all three driven directly from the engine, the work done in the arc was rather less than the work done when the two machines were supplying the arc and at the same time driving the third machine as a motor. These remarkable results are also borne out by the photometric results obtained during these experiments.

With the kind assistance of Mr. Longford and two of my students, Messrs. Anderson and Wordingham, I was able to measure the current, the electromotive force at the terminals of the machine and at the terminals of the arc, as well as the candle-power throughout the experiments. The photometer employed was Dr. Hopkinson's dispersion photometer, in combination with a star disc and a paraffin lamp with a Methven slit which had been standardised, and gave an illumination of 1 candle at the distance of 1ft. Ruby glass and ammonia sulphate of copper solution placed before the eye were employed to compare the intensities of red and blue in the two sources of light. By the Hopkinson photometer an illuminating power of 16,000 candles was reduced to six candles within a distance of 100in. from the arc. The illuminating power given by the arc fed by the current from one machine was measured at a distance of 50in. from the arc, and was found to be, with red light, 8,000 times, and with blue light, 16,000 times the light of one candle.

At the same distance, the current from two machines gave 15,000 candles, as measured by red light. For these and

* Paper read before the Society of Telegraph Engineers and Electricians on Thursday, Nov. 13th, 1884.

Digitized by Google

higher candle-powers it was found convenient to remove the dispersion photometer to a distance of 100in. from the arc.

The illuminating powers given by the current from two machines were then found to be 13,500 candles by red light, and 23,200 candles by blue light.

The illuminating powers of the current from three machines driven in parallel circuit were 16,000 candles by red light, and 31,000 by blue light; and when the two machines fed the arc and drove the third machine as a motor, the illuminating power was 17,300 candles as measured by red light.

TABULAR STATEMENT OF RESULTS.

	E.M.F. at the arc.	Current.	Watts in the arc.	Candles.	
				By red light.	By blue light.
With 1 machine....	33	175	5,775	8,000	16,000
With 2 machines {	35·5	275	9,750	13,500	23,200
	36	278	10,000		
With 3 machines {	37	300	11,100	16,000	31,000
	42 to 32	300	11,000		
	41 to 37	310	11,600		
With 2 machines, driving the 3rd as a motor.....	52 to 41	240 to 285	12,000	17,300	

ON THE ELECTRIC LIGHT.*

BY ALFRED RICHARD SENNETT, A.M.I.C.E.

(CONTINUED FROM PAGE 78.)

It will be seen from the diagrams that whilst the addition of reflectors to the alternating-current lights would have a marked effect on the intensity of illumination of ground area, they would be of little service to moderately short arcs, produced by uni-directional currents; and also that the distribution of light from the former is far more uniform than from the latter, especially when very short arcs (such as the Brush) are employed, and the

FIG. 8.

FIG. 9.

arc is not situated far above the horizontal plane to be illuminated.

With regard to the fluctuations in the intensity of the light emitted by the electric arc, with alternating currents, and with uni-directional currents of feeble strength and great electromotive force, the arc is in incessant vibration and motion around the points in its endeavour to pass by the path of least resistance, and in this they present a marked contrast to the fixity of the light emitted from arcs produced by currents of great strength and of small electromotive force working with a moderate length of arc. With a long arc or feeble current the colour of the light is less pure, being more violet or purple as a greater amount is derived from the arc proper and less from the incandescent electrodes. In addition to the greater stability of currents of low electromotive force, the light emitted by arcs produced by them is less influenced by any momentary vacillations of the current or movement of the arc; since, with feeble currents, the electrodes become heated only in the immediate vicinity of the points where the arc leaves and enters them, whilst with powerful currents a comparatively large surface of the electrodes becomes incandescent. Figs. 8, 9, 10, 11, and 12 serve to give a general idea of the appearance of the arc, with various dispositions of the electrodes. In each case the same (powerful) current was employed.

FIG. 10.

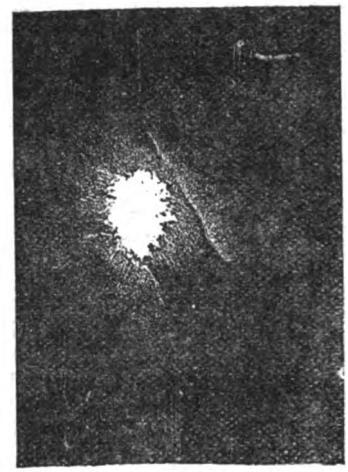

FIG. 11.

Fig. 8 is that of an arc of moderate length.

Fig. 9 represents an arc of the same power, slightly shorter, and with an upper carbon having a diameter 3 or 4 millimetres in excess of the lower one.

In Fig. 10 the front or crater side of an arc having the upper (positive) carbon about half its diameter in the rear of the lower as hereinafter explained.

In Fig. 11 the same disposition as seen from the side (=90° from the preceding view).

Fig. 12 is that of an arc set very short.

It will be observed (more especially in Fig. 12), how very much higher in temperature the positive carbon is than the negative.

For lighthouse purposes the arrangement of carbons already mentioned, namely, when the upper carbon is placed about half its diameter in the rear of the lower, so that its front edge nearly corresponds to a vertical line drawn through the axis of the lower, is generally employed. It is not of paramount importance that a lighthouse lamp should emit its maximum light in a perfectly horizontal plane, since the optical apparatus in which the lamp is situated has the effect of reducing to parallelism all the rays emitted; indeed, by placing the positive carbon below, a simplification of the apparatus is effected, for by thus giving the rays an upward direction, and throwing the chief work upon the upper catadioptric zones, a diminution in the number of lower catadioptric prisms is permissible. For military and naval purposes, however, it is necessary to have the maximum light in a horizontal direction, and for this purpose the carbons (arranged as previously described) are inclined at an angle of 20° with the vertical.

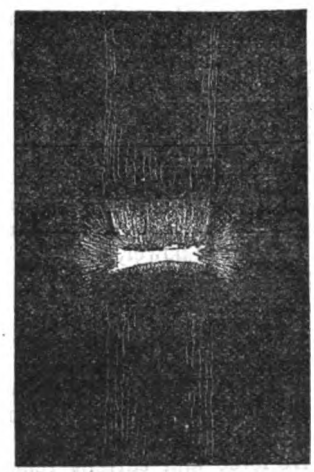

FIG. 12.

(TO BE CONTINUED.)

ELECTRIC LIGHTING IN AMERICA.*

BY W. H. PREECE, F.R.S.—*(Concluded from page 69.)*

II.—INCANDESCENT SYSTEMS.

Incandescent lighting in America does not seem to have flourished to the same extent as arc lighting, nor, indeed, has it been applied to private houses to the same extent that it has in England, although there are several central stations at work over there, which is not the case on this side of the water. The principal system in practical use is that of Edison. Some incandescent lamps have recently been introduced by Mr. Weston that promise to be very efficient indeed. They are made from a material that Mr. Weston calls "Tamadine," the result of some secret process upon nitro-cellulose. This tamadine is rolled out into very thin sheets, and the filament is stamped out in a wavy form by dies. It is then carbonised. Carbon is deposited upon this filament until it acquires a standard resistance, and the process self-acting, so that great regularity is maintained in the resistance of the filament. The whole process of manufacture is extremely ingenious, and I watched it in Weston's manufactory with great interest.

The Swan Lamp is extensively used, principally by the Brush Company.

The Bernstein, a new lamp, which was exhibited at the Health Exhibition, is also commencing to get a footing in the States.

House Lighting.—House lighting has been attacked principally by the Edison Company. The Edison Company have a grand central station in New York, which was opened on the 3rd September, 1882, and during the whole of the period that has elapsed from that time to the date of my visit there had been only two and a half hour's stoppage, that being due solely to carelessness. A commodious building in Pearl-street is applied to this purpose. There are now 587 subscribers, using altogether 12,764 lamps, served day and night; and the present arrangements of the Company are quite inadequate to supply all the applicants who desire the light. The price charged is the same as that which would be paid if gas were supplied at 7s. 9d. per 1,000 cubic feet, but there is every reason to believe that the rate is too small, and does not give a sufficient margin of profit. The price of gas is 9s. 2d. per 1,000 cubic feet. It is interesting, however, to know that the system is worked at a profit, and that during the past twelve months the balance on the right side has been sufficient to pay a dividend of 3 per cent. on the capital invested, but no dividend has yet been declared. The earnings per lamp-hour are 1·04 cents, while the cost of production for the same period is ·75 cents. The Board of Trade unit which was intended to form the basis of charges made for the supply of electricity under the hasty and abortive Act of 1882, in this country, was equal to 1,000 watt-power. Now an Edison 16-candle lamp absorbs 80 watts, and therefore 12·5 lamps alight for one hour would consume a B.T. unit. These lamps would cost in New York 15 cents. for that time, and therefore the charge made in New York is equivalent to 7½d. per B.T. unit. The average number of hours of lighting appears to be 2·4 per day per lamp. A record is kept of every lamp, so that the average life is known, and it comes out at about 477 hours. The consumption of coal is ·82lb. per lamp-hour, and there are five lamps per horse-power, rather a low result, due probably to the inefficiency of the old system of conductors. The average number of lamps per subscriber is twenty-one, while the average amount paid annually by each subscriber is £40. The difficulties that have occurred in practical working have arisen principally from a too free use of fuses, which have given much trouble by going when they ought not to go. The conductors have unfortunately been fitted with bad joints, and a good deal of annoyance has arisen from leaks in the mains; but all these effects are due to immature experience, and can readily be remedied in future extensions. The distribution of the currents is carried out by a network system of double mains which involves the use of an immense weight of copper. Dr. Hopkinson in England, and Mr. Edison in America, have shown how an economy of 60 per cent. in the weight of copper used can be effected by using three wires and two dynamos. This system is shown in Fig. 3, and it is now invariably used by Mr. Edison. The whole area of the portion of the city lighted by this system is about a quarter of a square mile, it covers fifty blocks of buildings and fifteen streets, and the capital invested is £200,000. It is intended to open two more central stations, of much larger dimensions, in the upper part of New York, and there is no doubt that with the experience gained, the troubles encountered in the old station will be remedied. At Roselle I saw an interesting installation. This is a small village in New Jersey. There 1,200 lamps were used, supplied by three dynamo machines joined up in series, the lamps also being worked in three series. Overhead wires were used, and the charge was 1 cent. per hour for each 10-candle lamp. This is equivalent to gas at 2·5dols. per 1,000 cubic feet.

Another very interesting central station, wired up on the new 3-wire system, was established at Brockton, a town about 17 miles from Boston. There were 2,090 lamps going, and 1,040 were about to be started. The station was installed in October, 1883, with 250 lamps, and the rate charged was 1 cent per hour for each 10-candle lamp. There were 108 subscribers. The capital of this company is 100,000 dols., 25 per cent. of which belongs to the parent company. The station has not yet carried a dividend, but the expenditure balances the receipts. The business is growing at such a rate that there is no doubt that at the end of the second year a handsome balance will be realised. It is in the hands of a very earnest worker, Mr. W. Lloyd Garrison, who is determined to faithfully test the commercial value of the new illuminant. I also inspected two large central stations in New York, worked on the Weston high tension system. One station worked 384 arc lamps, while the other was working 500 arcs and 1,750 glow lamps. All the details of these two stations manifested the same mechanical skill and solid appearance that I have already alluded to as indicative of the Weston system. In no instance could I perceive sufficient appreciation given to the value of a renewal fund to provide for depreciation. Some estimated the proper allowance for depreciation as low as 2½ per cent., and others at 5 per cent., but in no case did anybody exceed the latter figure. It is very questionable whether this is sufficient to allow for the decay and deterioration of electrical plant, especially of the conductors, which form such a very heavy item in the expenditure in England. I scarcely think less than 7½ per cent. should be allowed.

Conductors.—In all cases throughout the whole of the States, with the exception of the Edison system, the conductors are invariably aërial wires, generally of copper, protected to a certain extent with cotton or hemp covering, and supported by poles fixed along the kerbs of the streets. The high tension currents are always used, and up to the present moment the freedom from danger has been very marked. A considerable amount of trouble has been caused to the telegraph and telephone companies by these powerful electric light currents finding their way into the telephone and telegraph circuits by contacts. I traced no less than seven fires in offices which were undoubtedly due to these causes. The Edison Company have not yet established a central station in Chicago. The chief reason adduced for this is that they have not been able to obtain the consent of the Town Council to place their wires underground, although this same Town Council has ordered all the telegraph and telephone wires to be put underground.

Secondary Batteries.—The use of secondary batteries has not received so much attention in the States as on this side of the water. The form most generally in use is that of Mr. Brush, which is a modification of the Planté cells, and is said to give very good results. Another modified Planté I saw in use at Philadelphia, made by Dr. Starr. The positive plates were composed of a solid frame of lead, filled with thin inverted V plates arranged "herring-bone" fashion, the interstices between which were filled with fine lead shavings. These plates are specially prepared by some process that I did not learn, so as to save the time lost in preparing them as required by the Planté method. The experiments that have been made with the Faure secondary battery were not well spoken of.

Instruments for Measuring Purposes.—The point connected with electric lighting to which I devoted a considerable amount of attention was the practical working of Edison's method of measuring the current used, by the electrolytic action of a small portion of the current upon two zinc electrodes immersed in a solution of sulphate of zinc. In all the central station systems based on the Edison arrangement, this mode of measuring is adopted, and it is said to give reliable results. The measurements are undoubtedly based on accurate formulæ, and if all the conditions are fulfilled, the results must be perfectly true. It is scientifically accurate, and is based on the system used to standardise all current measurers. The bottles containing the solution and the zinc electrodes are collected every month, and, in the Edison district of New York, two men are employed whose sole duty it is to collect and measure these "meters." The plate which has suffered loss of zinc is removed from each bottle of the meter, dried, and carefully weighed. The mean between the two measurements is taken as the true one, and this weight of zinc lost, in milligrammes, multiplied by a coefficient, gives the number of dollars to be charged for the light consumed during the month. The charge made to the consumer, though based on the current supplied, is really charged on the light given, and it is 1 dol. per 1,000 candle-hours. The weight of zinc lost is made equivalent to so many candle-hours, and the subscribers therefore pay for the light they receive and not for the current they use. There are 1,160 bottles out, 50 of which are measured every day. No trouble whatever is experienced in measuring them, and they are unquestionably accurate within 1 per cent., which is more accurate than any existing gas meter. When a meter is taken away for measurement, it is immediately replaced by another one, so that there is no break in the record should consumption be going on. The charges to the consumers are based on these measurements. The consumers themselves have taken various steps to check the reliability of the meter returns, and the result has been that the public has gained confidence in the accuracy of the measurements and the charges made.

ELECTRIC LIGHTING OF SHIPS.

The electric light has been applied to a great extent to the lighting of ships. The great ferry boats of the Pennsylvania Railroad are so lighted. Those magnificent hotel steamers that ply between New York and Fall River, and those on Lake Superior, as well as those on the Mississippi and other large rivers, are either wholly illuminated or are gradually being fitted for that purpose. The fittings on such a steamer as the "Bristol" are very complete, and were carried out by the Edison Company. Special engine rooms are provided for the electric light machinery, and the fittings throughout contain all the most recent improvements, and form a very admirable installation. All the great passenger steamers crossing the Atlantic are being fitted, and the comfort of the passengers in consequence is inestimable.

GENERAL COMMERCIAL POSITION.

The problem as to whether electric lighting is practical, and as to whether that means of illumination can be made to pay, has been thoroughly solved in the United States. The great mistake that has been made there, as it has been made here, has been the attempt to enter into competition with gas. The Edison Company started on the basis of the charges made for gas, and the result of the two years' working has been to show that this was a financial mistake. Electricity must earn its future success entirely upon its merits and not on its economy. In the case of street lighting it has proved itself to be a good thing, and if once a thing is proved to be good in America, it is immediately taken up; "Progress" in that country is the word. Novelty is a certain criterion for consideration. Manufacturers do not hesitate to clear out their entire factory if they find that they can get cheaper and better work by entire renewal. So with the electric light. If it proves

* Paper read at Society of Arts on Wednesday, December 3.

Digitized by Google

itself (as it unquestionably does) to be a better light than gas, then gas-fittings will be instantly removed, and electric light fittings substituted, without particular reference to the cost, so long as it is reasonable and within the means of the consumer. I have said more than once that at the present day we can only regard the electric light as a luxury, and we must pay for it as a luxury. But there is no reason why it should always remain a luxury. There are various chances of economy which justify the conclusion that, sooner or later, the price will be brought down so as to relieve us of the use of the term luxury as applied to it. For instance, the output of the dynamo can be extended, which has already been done with several types, particularly, as I have pointed out, in the case of the Brush pattern, where 60 arc lamps are now lighted where only 40 lamps were supplied by the earlier and unimproved machine. Again, considerable reduction in the weight, and therefore in the cost of the conductors, has been reduced by the production of the three-wire system. Moreover, when existing patent rights lapse, the manufacture of dynamos will become general, and the consequent competition will no doubt result in the production of efficient machines at a sum far below the cost of those made under existing patent rights. The efficiency of the glow lamps has also been very considerably affected by the improvements made, for instance, by Messrs. Woodhouse and Rawson, and by Mr. Bernstein. The efficiency of the Edison lamps means the consumption of energy at the rate of 5 watts per candle with an equal life, but lamps are now being made which give an efficiency of 2·3 watts per candle, which is equivalent to an immediate reduction of 50 per cent. in the amount of energy required to maintain the system alight, and therefore at the cost of its production. There is still vast room for economy, and it is quite clear that the prices which are now necessary to make the electric lighting pay must not be regarded as final; they will be brought down. Even now it is possible in England to make a system pay at the rate of a halfpenny per glow lamp per hour; and no one who has ever experienced the charm and comfort of the electric light, and who has electricity brought to his door, and supplied to him at this rate, would hesitate to pay that figure for the use of electric lamps, although he could obtain the same light by gas at less than half the price. There is a point that will lead to the introduction of the electric light that is very marked in the United States—viz., its influence, when applied to the streets, upon the the morality and safety of the public. The Chief of the Police of New York has gone so far as to say that "every electric light erected means a policeman removed." This, though probably got true as regards actual numbers, is so far true in fact, that the supervision of the streets and thoroughfares is rendered far simpler when they are brilliantly illuminated by the electric light. Its moral effect is principally to be noticed by the way in which it has checked the formation of crowds, and disturbed the haunts of those who, unfortunately, infest most great towns and cities, and who render the streets of London at night a disgrace to modern civilisation.

COMPANIES' MEETINGS & REPORTS.

The Swan United Electric Light Company (Limited).

The second ordinary general meeting of this Company was hold on Wednesday at the Cannon-street Hotel, Mr. J. S. Forbes in the chair.

The SECRETARY read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: I shall trouble you with a very few remarks. I am very sorry to see so small an attendance of shareholders. I wish they would come here themselves instead of sending their proxies. A great number of shareholders have been good enough to send their proxies, representing about 35,000 shares, but it would be much more satisfactory if people really largely interested would attend the meeting and assist the Board. However, we must take it for what it is. The report we have made as full as possible, in order that you may see without any very long story from me what the position of the Swan Company is. In respect to the asset involved in what is called the foreign patents, a good deal of what I should have said on that is rendered unnecessary to-day by the preliminary meeting of the people associated together—now happily, I think, associated together—in the Edison and Swan Company. We had there a very long story; we had a good deal of criticism, and we came to a certain conclusion. The Board, in whom for the present the shares of the Edison and Swan shareholders are vested as trustees, announced their perfect readiness to retire if the proprietors think fit, or to carry on the business to a conclusion if the proprietors think fit. Now, we did not think it seemly to take any resolution at that meeting; we thought we would wait the issue of to-day and of an Edison meeting, which I suppose will follow, and hear what the general view of the proprietors is. I had better just explain what the position has become. Of course there are a great number of wise people who can always prophesy after the fact, but who, not knowing very much about it, having very little sense of the facts, can always put everybody right, and can tell you that everything that has been done has been wrong. We are quite satisfied that to fuse with the Edison Company was a wise thing to do; and having fused we must make the best of it. But it places the members of the Swan Company in a rather difficult position as regards the existing Edison and Swan Company. They have no legal vote at present, nor can they have until they have got possession of the shares of that Company, which represent their interest in that Company. They can do what ordinary shareholders under the Articles will do, elect or reject; in fact, have the control of their own business. Until then they must be satisfied to be in trust, and I think it will turn out that this is a very good thing for them. We shall see. With respect to the other asset, that covered by what is callled the foreign patents, it is competent in the Swan proprietors to act, and you will find that this balance-sheet and statement refers exclusively to the business conducted under that part of the affair. Now, I had better just in a very few words tell you where we are. If you will cast your eye upon that balance-sheet you will find that it is one to the end of the year ending 30th June, 1884. You will find there what the share capital of the original Company is—19,750 shares of £5 each fully paid and 80,000 shares of £5 each upon which £3 has been paid; that represents £339,200 in round numbers. Well now, under the fusion with the Edison and Swan Company we could only put in a portion of the business, to wit the British business, and in respect to that partnership the shares in the new company were divided in certain proportions—a matter of agreement, not done without consideration or a certain amount of knowledge of the affairs of both companies, and upon a principle which I explained very fully the other day, and I do not think I need go over the ground again, because every proprietor had the report of the United Company sent to him. I suppose every proprietor has by this time received a report of the proceedings. I took the opportunity of stating the matter very fully then, and I think I stated it as clearly as it could be stated, and in language so plain that I think anyone using ordinary comprehension could understand perfectly the story. We have in that Company a certain number of shares alloted to us. We took in respect to the British interest so many paid up shares and so many shares that at that time had £2 10s. paid upon them, and we shall have to deal with the capital account of the Swan Company upon that basis. You now, instead of having one share in the Swan representing a united interest, have a share representing a partnership in one undertaking and a separate asset in another, and as nearly as figures will bring it out it is something like this:—We have 61·46 per cent. in the United Company, and, of course, the balance, 38·54 in the separate asset. Well now, what are we to do with this separate asset? Of course the Swan proprietors of the Swan, when the shares of the United Company are distributed, will be proprietors to that extent of the United Company. They will remain proprietors of this separate asset, and the only practical way to deal with it will be to devise some means by which the present share shall be split—the shares of the United Company distributed in respect to the 61·46 and some other instrument or share in some other form must be created to represent this foreign business. That is the skeleton of the future thing. Well, we have considered what should be done with the foreign business. Is it to be carried on or fused with the United Company? There are some arguments in favour of fusion, and some against it, and the latter prevail. A fusion would raise questions of some gravity and some difficulty in respect to the interest of the Edison proprietors in the United Company, and especially in regard to the deferred interest which Mr. Edison holds in that company, because, as I explained, whereas the patents of the Swan Company had been bought out and out either for money or shares—a very unwise proceeding as it has turned out—I think Mr. Edison's patent was represented by deferred shares, and we had a good deal of difficulty in bringing Mr. Edison to terms in respect to his deferred interest when the British interests were fused. I think we should have a good deal more difficulty to bring him to terms in respect to the foreign patents, because he has sold them to other people and has no interest in them, and as a man of honour might feel some difficulty in being a party to the transfer to his own company here in England of a business abroad, which may be, and probably will be, in severe conflict with the interests of the people from whom he has already received consideration. At all events, we determined the proper way would be to carry on the foreign patents and foreign business as a separate asset of this Company—that is to say, if there is a reasonable probability of these patents turning out to be worth anything, and a reasonable probability of the business being conducted to a profitable result. That being the policy we have to consider, I shall come presently to a resolution I shall have to propose on that subject. Meanwhile, having reminded you that you are here to-day dealing with this report and this balance-sheet merely with the state of the foreign business, or with the separate Swan Company, I do not know that I have very much to say, the report is so very full. We thought it desirable to make it as full as possible, in order that shareholders may not only be able to draw from it what information they can, but what comfort they can. The best, I think, that can be said of it is that it is less bad than the report of the United Company, as showing that the loss on the working of the thing has been less considerable. But the very same reasons which I adduced in explanation of the state of things which I had to bring before the proprietors a few days ago hold good. In fact, more than hold good, because, first of all, the business is spread over a much wider area than the British patents, and had to be conducted much more cautiously and with more difficulties, legal and otherwise, and it is the same story, on all fours as to the difficulties at home, where we were led to fusion in order to escape litigation. We are in litigation in half-a-dozen cases, and until that litigation is terminated it would be very unwise to commit ourselves to any very large expenditure of money in forcing these patents and doing this business abroad. Still, we are sufficiently far advanced to have thought it desirable to make a start. The report will tell you what has been done; it explains why the financial result on the profit and loss account is not very satisfactory. But the truth of the story is that until you get this business founded the fixed expenses must bear an enormous proportion; in fact, must swallow up the first fruits of a small business. The only thing to arrive at is this:—Is it a business that will grow? Will the volume of it be so increased as to reverse that state of things? Well, we think it will; and because we think it will, and because some of us are largely interested in the matter, we have made up our minds to prosecute it. I think I may say I am speaking the feelings of those around me when I say that we are all agreed that this foreign business is a good business, which offers certainly quite as good a future as the

Digitized by Google

English business, if not a better. Well, if that be so, what is to be done? What we should recommend you to do is to carry it on. We have established factories at Lille and Cologne. We are in litigation in two or three places, notably at Cologne. One can never tell abroad, as in England, what the ulimate result of legal proceedings may be. I think we have drawn first blood—at all events we have a technical decision in our favour to this extent, that whatever may be the merits of the Swan patent, it is not an infringement on the Edison patent, because that is what they are fighting about abroad. Whether that view would be maintained at home one does not know; one never knows the result till judgment is given. We thought it wiser here not to provoke that judgment. I do not know whether the Edison people abroad will be induced to do what the Edison people at home have done and what we did—put their horses together. If they do not we must fight on in the sense of defending an attack. It is defensive fighting. In the face of all that, notwithstanding the bad result of this balance-sheet, notwithstanding the very large sum of money paid for these patents, our opinion is you will be wise to go on, and not to throw up the sponge upon the result of the first year or two's business. Of course everybody has been a little disappointed. Plenty of people can prophesy after the fact. The world was a little mad about the electric light a short time ago, and I am not sure they are absolutely saner now, and when your bargain was made no doubt you paid too much, but without indulging in prophecy, bad as it stands on this paper, I do not think the amount paid or the sum of money invested is so very appalling as to induce people to draw back without spending a little more money. No doubt it is a very bad policy to throw good money after bad, but sometimes it is done to get good money back. And that is what we shall recommend you to do—to go on with this thing. Well, then you will see what the result of it all is. There is a great demand going on for these lamps, because after all, as we said before, that is the best part of this business. If we can limit ourselves to the manufacture of lamps, and if we can find a business and maintain a sale in sufficient volume of these lamps, we have a good factor for a profit on all the money sunk, even supposing we should have to give up installation work or public lighting. Well, I do not think we need do that. I believe in the future of this Company. Both here and abroad there is a great deal of useful installation work on which a large profit may be made, but for the present we think it would be wise to limit ourselves as much as possible to lamps and that class of installation work which means ready money for what you do. I do not think we shall be easily tempted out of that path, and if we continue it with reasonable care, in the opinion of the Board there is no reason to doubt that, notwithstanding our position, which does not look very satisfactory now, about which I see some people howl a little, and take a gloomy and desponding view, as people always do in that frame of mind—ignore palpable facts, strain inductions, and generally make a mess of it—notwithstanding that, I think we shall get through. Now I have no doubt there are some critics in the room, because I see the mover of an amendment which was made the other day at the meeting present. I should like to hear what those critics may have to say before I make any further remarks, and if it is deemed expedient to give information I shall be very happy to do so; but, meanwhile, I shall move the resolution that the report and accounts be received and adopted.

General TREVOR seconded the motion.

Mr. BALFOUR said there must have been mismanagement on the part of the Directors, the Chairman, the Managing Director, or someone whom they employed, or the Company could not have drifted into such an unsatisfactory state. Twelve months ago the price of the shares, with £2 10s. paid, was £1, but now with £3 paid it was only 1s. 6d. to 2s. 6d. He said that in July, 1882, several of the Directors reduced their holding of shares to their bare qualification, and argued that from that fact the Board at the time must have known that the Company was not going on in a satisfactory manner. He thought they should demand a pledge from their Directors that no further call should be made without calling the shareholders together, to tell them in what manner the money was to be spent. He thought also that like every other Company they should meet twice a year; and he suggested that the retiring Directors should not be re-elected, and that a committee of ten or twelve large shareholders should be formed to recommend three gentlemen for a seat at the Board.

Mr. KEMPSTER moved the following amendment:—"That in the opinion of this meeting it is not desirable to adopt the report and accounts now presented; but this meeting would urge the shareholders to combine for the protection of their property, and to this end would seek the active co-operation of the large and influential shareholders, by whose aid it may be possible to control the management of this Company and the Amalgamated Company; and this meeting is of opinion that no fees should be paid to Directors except out of the profits of the said Companies." He thought that if a resolution of that kind were adopted it would have a moral effect, and the shareholders who were absent and had sent their proxies would see that the gentlemen in London, who had had the opportunity of discussing the matter, were not quite so simple as themselves. He thought they should have a poll taken in order to see who were the persons who supported the Board, and although they were told they could pass no legal resolution he thought the adoption of his amendment would have a moral effect. There was great reason why the report should not be adopted, because if it were the shareholders would be told that they had endorsed and approved everything that had gone before; therefore, he solemnly warned the shareholders not to adopt the report and balance-sheet. There were sufficient grounds for suspicion that all was not right. They had heard of the enormous sums of money paid for patents, and it had been suggested by one of the financial papers that those large sums of money had never found their way into the pockets of the two gentlemen to whom they should have been paid—Mr. Swan and Mr. Edison. That was a very serious statement, and they ought to be thoroughly assured that it was absolutely false if it were so. If that money had gone into the pockets of any people who occupied a fiduciary position they were entitled to have it back. Twelve months ago the Chairman said that if at the end of a year they found their capital intact that would not be a bad outcrop; and if the Chairman did not know then that they were on the horns of a dilemma he must have been incompetent. Mr. Forbes also said that he believed that they had arrived at the threshold of a grand future, and they must now carefully feel their way—did Mr. Forbes at that time believe that?

The CHAIRMAN: I did believe it, and I do believe it now.

Mr. KEMPSTER continued that at the meeting last year the shareholders had the distinct assurance that the Directors would not make a call unless the money could be profitably employed; they had made a call, and the money had not been profitably employed. He contended that they were virtually in the hands of certain large shareholders, who were either the promotors of the Company or who had been connected with the promoters.

Mr. SWABY seconded the amendment.

Mr. LEYLAND said that the Company was in a critical condition, and it might result seriously if they attempted to interfere with the present management. However, he suggested that now the Directors had determined to take steps for the distribution of the shares.

Mr. QUILTER was very glad that Mr. Kempster had had the boldness to attempt to substantiate the hints that had been thrown out in the articles of that very "independent financial paper," because it enabled him to give a few statements which would at once and for ever, he thought, set at rest in their minds any suspicion that there had been anything in the formation of this Company which any committee of investigation, no matter how hostile, could say was not straightforward and satisfactory. The preliminary expenses amounted to £624 10s., which sum included the commission to the brokers, none of which money was paid to himself. The only payment he received was a fee from Mr. Swan at the time when he undertook the formation of the Company, and he took shares to three times the amount of the fees he then received, and he now held those shares. That showed his faith in the Company. He now fully shared the faith of the Chairman, and still believed that with good management the future of the Swan was a promising one. He stood now to lose five times the amount of the fee he had received, and he believed that about a third of the shares of the Company were taken by his own friends, and a very large majority of those shares were now held by them. Mr. Crompton had received every penny he was entitled to. Mr. Swan had received every penny to which he was entitled, and therefore he had great pleasure in saying that there was not a particle of truth in the insinuations that had been alluded to.

Mr. STEVENSON, M.P., said that when the Newcastle Company was transferred to this undertaking he invested the whole of the money he got for his shares in that Company in the shares of this Company.

Mr. LEDGER asked the Chairman how many times he had attended the meetings of the Board of the Swan Company. He put that question with all due respect.

The CHAIRMAN replied that he declined to answer. He would decline altogether to enter upon any personal matter.

Mr. LEDGER: I wish to show the interest you take in the Company.

The CHAIRMAN: It shows how very little you know about the matter.

A SHAREHOLDER said that Mr. Forbes was undoubtedly a most able man, but he thought they should know what attention he had paid to the interests of the Company.

The CHAIRMAN said that if they would like to know, since the Swan Company proper transferred its business, the most complicated and the most difficult to the United Company, he had been most assiduous in his attention to that part of it. It was most difficult and involved. He doubted if any gentleman in that room had any knowledge of its perplexity or difficulty. He thought he might claim for himself the credit of having been the chief means of bringing about the fusion upon terms which he regarded as most favourable. With respect to the business of the Edison Board, they had met no doubt a great many times *pro formâ*, but they had no control of any kind with the manufacture of business in England. They had a competent Managing Director in Mr. Stearn, and he thought if the Swan Directors were wise they would leave Mr. Stearn alone, and not interfere too much with him. But if it were supposed that attendances at formal meetings were a measure of a man's knowledge or capacity to conduct an affair he begged to say it was not. Fortunately he was associated with gentlemen who would be able to form a correct opinion as to whether he had or had not discharged his duty. He had a great interest in the Company, and he was quite satisfied himself with what he had done in the Swan Company and the Swan United.

Mr. LEDGER: That is not answering my question. I asked how many times you have attended at the office.

The CHAIRMAN: I cannot tell you. If you ask how many times I have been in the office—a great many times.

Mr. QUILTER said that he had been entrusted with a large number of proxies, and thought it would give satisfaction if some of the largest shareholders were to confer with the Board. Many large shareholders felt that they ought to be more directly represented on the Board. He appealed to Mr. Kempster to withdraw the amendment.

The CHAIRMAN asked if Mr. Kempster desired to press the amendment.

Mr. KEMPSTER said that he must press it, as he wanted to test the feelings of the shareholders.

The amendment was then put and lost, 14 voting in its favour.

The resolution for the adoption of the report was then put and carried.

Mr. KEMPSTER demanded a poll, but in deference to the general wishes of the shareholders the demand was withdrawn after some discussion.

The CHAIRMAN said that the next question was the re-election of Directors, and if anyone was particularly anxious for his seat he was perfectly welcome to it. With regard to the statements that had been made in a certain paper, all he could say was that they were absolutely untrue, and the inferences were absolutely untrue, and they must have been

Digitized by Google

written for some dastardly purpose. Mr. Kempster's arguments had been based on a total misunderstanding of the nature of the Company. He had exhibited an entire ignorance of the A B C of this Company; he did not even know the nature of the agreement between this Company and the Edison Company, and wanted light upon that which the most casual perusal of the agreement or the most superficial knowledge of the Company would have given him. Mr. Kempster was very much in doubt as to what the position of the proprietors was as to calls, but he need not have been, for he could have come to the office and asked him (the chairman) or anybody equally competent, and all his doubts might been dispelled. With regard to the protest that had been issued he did not think it was worth while to comment upon that except to say that it was mere stuff. It was a very long-winded protest, without the shadow of foundation in it, and was issued no doubt to damage the interests of this Company. He did not think it was worth while dealing with it. Any man who took for his text the vilification of individuals ought not to be listened to, and he considered that all men who did that ought not to be answered. That was his opinion about them. If the proprietors of this Company considered that his resignation would do their concern good, in heaven's name let them discharge him; because it was quite enough to have the responsibility and the serious wear and tear attached to the administration of the concern; but if in addition to that the Board were to be attacked in a scandalous manner it was an atmosphere no gentleman cared to live in. He was not, however, going to be forced out of his seat by a cabal. Men of the first position had trusted him in this as in other things, and he had always been faithful to them till he had pulled them out of their difficulties, and that was what he was going to do here. He was not going to be hounded out of the chair by those who had no real interest in the Company.

Mr. SWABY: I have spent £900 in this Company.

The CHAIRMAN: Well, spend a little more.

Mr. SWABY: That I decline to do.

The CHAIRMAN could not help it; he could only advise Mr. Swaby to buy more shares. He was not going to be hounded out of the chair by gentlemen who had no knowledge and nothing but angry feeling. He was not going to be hounded out of the chair as long as he had the confidence of the large proprietors, who were legally and, what was more, morally entitled to control the thing, and as shareholders were utterly incapable of acting for themselves in matters of this sort, they must trust somebody who would act for them. He would act for them if he could, and if he failed, then let the people who had a solid interest in this concern invite him to retire, and he would not fail to do so. He had a great many other things to do besides looking after this Company. With regard to the price of the shares, he did not think that that was a true index of their real value, and why people should be such idiots as to sell their shares for 2s. he could not imagine. They had substantially all now that they ever had, and he believed they were in just as good a position as ever they were in, if the original purchases were justifiable. With regard to the re-election of Directors, if the shareholders wished it they might postpone the consideration of that question in order to find some one who had a large stake in the concern, and who had a right to a seat at the Board, but as to a committee of investigation or anything as a means of getting on the Board he did not mean to submit to it.

After some further discussion it was resolved that the consideration of the re election of the retiring Directors should be postponed for a week.

The CHAIRMAN said that the Directors wanted the shareholders to call upon them to take the necessary steps to distribute the share certificates, and he therefore moved—"That the Directors be requested to take the necessary steps for distributing amongst the shareholders the shares of the Edison and Swan Electric Light Company (Limited)."

General TREVOR seconded the motion, which was carried.

A vote of thanks to the Chairman then terminated the proceedings.

Great Western Electric Light and Power Company (Limited).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel, on the 8th inst., for the purpose of considering, and if deemed advisable, of passing the resolutions referred to in our last issue. Mr. J. B. Braithwaite, jun., presided.

The SECRETARY (Mr. H. P. Allender) read the notice convening the meeting.

The CHAIRMAN said that before he made the short statement which he proposed to make on this occasion, he thought it would be a convenient course to adopt if he asked their solicitor, Mr. Crisp, to give them a short substance of the provisional agreement which it was proposed to approve, or otherwise, at that meeting.

The SOLICITOR accordingly mentioned the salient heads of the agreement, which he said was dated the 28th ult., and it was conditional on its being approved by the shareholders before the 23rd inst. The fifth clause would be the one to receive the principal consideration of the shareholders. It was as follows:—"As further consideration, the liquidators shall, within fourteen days after the passing of the special resolution for winding-up the Western Company, pay to the Directors of the Western Company, out of the cash belonging to the Western Company, a sum of money equal to 10s. in respect of each share upon the written personal undertaking of the Directors to apply such sum of money in payment of a dividend of 10s. per share to the shareholders in the Western Company on each share held by them; and in addition to such payment as aforesaid each member of the Western Company shall be entitled to require the Brush Company at any time within three calendar months from the date hereof, to allot to him three fully paid-up £5 shares in the Brush Company in respect of every twenty fully-paid shares in the Western Company held by him." There were some provisos as to how the requisition was to be made, as to fractional certificates, and as to paying any dissentient member. The Brush Company were to accept without investigation such title as the Great Western Company had to all their property. If not approved before the 23rd instant the conditional agreement would become void.

The CHAIRMAN said it would not be necessary for him to detain them for many moments on that occasion, as he trusted that the substance of the agreement, as stated by the solicitor, combined with what the Directors had stated in their circular, would have made the terms of the proposed amalgamation quite clear. He might mention in the first place that when they last met about two or three months ago they little thought they would have so soon to meet the shareholders again, or have any proposal of the nature then before them to submit. It was about a month or six weeks ago that the Brush Company made overtures to them, and inquired on what terms they would be prepared to make over the Company to them, and the result of the negotiations was the offer before them. The Directors tried to draw up their circular so as not to bring any pressure on the shareholders in any direction, as they wished to leave it to them to decide whether they would accept the offer or not. They had, however, received proxies to be used against the proposal representing 334 shares, and proxies to be used in its favour representing 14,509 shares; and in addition they had received the concurrence of Mr. Edwards, the liquidator of the Devon and Cornwall Company, that he agreed to the amalgamation on behalf of the 3,000 shares to be allotted to that Company. That represented about 18,000 shares in favour of the amalgamation out of a total of 27,800. Two or three of the shareholders had written under the impression that the fully paid-up Brush shares they were to receive were £10 shares. That, however, was a mistake, as the capital of the Brush Company had been reduced by one half, and it was therefore £5 shares which they would receive. The direct value of the offer made was as follows:—They had 28,618 shares, including those to be allotted to the Devon and Cornwall Company. The Directors had reserved to themselves the right to distribute among the shareholders the bulk of the cash in hand. The amount would be practically £14,000, or 10s. for every share held. Each shareholder would also receive for every share he held 15s. in fully paid Brush shares taken at par. The present market price of the Brush share was 3½, so that at the present market price of those shares the shareholders would receive altogether £1 0s. 6d. per share held by them in this Company. Looking at the balance-sheet, supposing they went into liquidation they would not be able to give the shareholders as good a return as that. Looking at it from every point of view, and that there was a prospect for electric lighting, he thought the shareholders had done wisely in electing to accept the offer, as they would receive shares in a company which was solvent and in a position to carry out its contracts. The Directors felt, after taking office as they did to try and rescue the Company from the wreck it had been about to be involved in, that they ought not to hand it over on any principle of taking shares in the Brush Company unless their position was sound. He and Mr. Reynolds, therefore, had a long interview with Lord Thurlow, the Chairman of the Brush Company, and the whole position of that company was laid bare to them. They asked all the questions which the shareholders would know would readily suggest themselves on such an occasion, and they were answered in the fullest and frankest manner. With those answers they were quite satisfied; and on the strength of that interview they were there to say that they thought the shareholders had acted very wisely in giving the Board such a large majority as they had in favour of the proposal. It should be borne in mind by the shareholders in considering this offer that while the capital of the Brush Company had been reduced to one half of its original amount, the capital of this Company remained the same; and therefore every £5 share which they were going to get of the existing Brush Company was equal to £10 of their stock as it was when it was started; so, assuming that they were back in those days, the shareholders would get 30s. instead of 15s. in the shares of the Brush Company, and 10s. in cash, thus representing £2 of the original £2 10s. He concluded by moving *en bloc* the resolutions above referred to.

Mr. STEWART briefly seconded the motion.

Mr. BACKHOUSE said he wished to ask a few questions; and, first, the Chairman had stated that there were 27,000 odd shares. According to the last report, however, there were 24,744 shares, and 3,000 had to be given to the Devon and Cornwall Company. This made 27,000 odd; but off that number had to come the number given by the Brush Company for the purchase of certain rights from the Company.

The CHAIRMAN said that if Mr. Backhouse looked at the balance-sheet he would see that the 1,150 shares which they received from the Brush Company had been deducted from the amount of the capital before the amount mentioned by Mr. Backhouse had been reached.

Mr. BACKHOUSE said he presumed that it was open to the shareholders to move any amendment.

The CHAIRMAN: Decidedly.

Mr. BACKHOUSE said he would move "That the offer made by the Anglo-American Company be refused." He happened to be in Manchester last week, and made some inquiries as to the electric light and the progress it was making, and also about the Brush Company particularly. He was fortunate enough to meet with a gentleman who had a great deal to do with electric lighting, and he heard that it was spreading very much, and that the Victoria lamp of the Brush Company was acknowledged to be one of the best in the market. The offer which they had met to consider had been made unexpectedly to the Directors. He thought from their circular that they had considered the matter in a strictly impartial light, but he now gathered from the remarks of the Chairman that he was quite of opinion that the shareholders of the Company would be right in accepting the offer. According to the balance-sheet last presented to the shareholders the Company had over £16,000 in cash. He had thought

Digitized by Google

that the Chairman would perhaps have stated what the amount of cash was at the present moment, and whether much of the sum mentioned had been lost since the meeting. Taking it roughly that there was something like £16,000 at the bank, and that the face value of the land and other assets was worth £13,700, the Company had altogether about £30,000 in cash and property, which the Brush Company would get. For that £30,000 they offered this Company £12,700 in cash, and of that over £1,800 would go to the Brush Company, so that the whole of the cash they would pay this Company would be about £11,000.

The CHAIRMAN stated that the amount of cash the Company would receive was £13,900.

Mr. BACKHOUSE, continuing, said that in that case the amount would be reduced in a similar manner to £12,000. The whole of the cash the shareholders would get would be £12,000 for the £16,000 they possessed; and for the plant, &c., possessed by them they would receive the face value in shares of the Brush Company. For their patent rights, however, which they purchased two years ago of the Brush Company, they would get nothing. He believed that over £20,000 was paid by the Company to the Brush Company for those rights, besides £15,000 in shares, and they would get not a single farthing in consideration of this. He happened to know that an offer had been made by the Brush Company to buy up another of the subsidiary companies. Knowing that the Victoria lamp made by the Brush Company was admittedly one of the best, and believing that the prospects of the electric light were better than they had ever been, it seemed strange that the Brush Company should ask the shareholders of this and other subsidiary companies to surrender for nothing whatever the rights for which they had paid three-fourths of their capital. Whichever light the offer was looked at, it seemed to him to be an extraordinary one. In their last report the Directors stated that the Brush Company had given them back 2,300 of their shares in the Company for the right to light up railway trains in the district of the Company. They made the concession believing in the value of what they acquired. When the Devon and Cornwall Company was wound up 3,000 shares were given to them. How was it that they were proposing to deal with the Brush Company in a totally different manner from that in which they had dealt with other companies connected with them? The proposal seemed to him to be outrageous and unfair. If Brush shares were given to them to represent the £20,000 in hard cash which had been paid by them to the Brush Company, it would be some acknowledgment for the rights which they were now asked to give up for nothing. With regard to the shares of the Company held by the Brush Company, it was, he contended, monstrous that those shares were not surrendered. Whatever money was divisible ought to be divided among the shareholders of the Company. It seemed to him a most one-sided offer, and he trusted that no shareholder would sacrifice his property for about half its value. He moved that the offer be refused.

The SOLICITOR: That is not an amendment. It is a negative.

The CHAIRMAN: That is a direct negative.

After a few observations from Mr. Heath,

Mr. WATERS pointed out that in accepting the Brush shares they were accepting shares in a company the original value of whose patents had been wiped off. The shares were thus really double their existing par value.

The CHAIRMAN, in reply, said he thought, as Mr. Waters had pointed out, the remarks of Mr. Backhouse rested on a misconception. He was not there to urge the shareholders to adopt the offer. In sending out their circular they abstained from making any suggestion, but after the very large preponderance of votes which they had received through the proxies in favour of the offer, he felt it his duty to carry out the wishes of those shareholders as far as possible. Mr. Backhouse seemed to have lost sight of two or three very important facts. He had lost sight of the fact which he (the chairman) and Mr. Waters had called attention to—namely, that each Brush £5 share represented £10 of the original capital of that Company, so that if they were to go back to the time of their concession they would be getting by the offer 30s. instead of 15s. in Brush shares. As to the amount of cash at the credit of the Company, it was very much what it was when their balance-sheet was issued—between £16,000 and £17,000, with their debts, and the bulk of this they would distribute to the shareholders. The remainder—it was a small amount—they thought it only right that the Brush Company should have, as two stations would be handed over to them—Bristol and Cardiff. According to their last balance-sheet, their property and plant and cash represented £30,000, and in exchange for that, taking the Brush shares at their par value, they would receive £34,740, so that the effect was to liquidate the Company at their own valuation, without any of the costs of doing so. He was very glad to hear Mr. Backhouse testify to the excellence of the Victoria lamp; and it was on that fact, their excellent incandescent lamp, their prospects of business, and the result of their eight months' work that the Directors went. He could not but think that they would be very wise in accepting the offer which had been made. As to Mr. Heath's question respecting the case of the Devon and Cornwall Company, the Great Western Company had a claim made against them amounting to £29,000. That claim would have made them entirely bankrupt, and had they fought it out in the courts of law it would probably have involved them in very heavy expenditure. They therefore made an arrangement which was thought fair and equitable on the whole to both sides. The present case was of a very different character. They were not bringing an action against the Brush Company, but that Company had come and asked them on what terms they could go into amalgamation with each other.

A SHAREHOLDER asked what remuneration it was proposed to pay the liquidators.

The CHAIRMAN replied that no arrangement had been made, but the question did not affect them, as the expenses would fall on the Brush Company.

Mr. REYNOLDS stated that he would accept no remuneration whatever. He would be only too pleased to help the Brush Company and to assist them in their business, which he thought this Company had done a good deal to help on.

The CHAIRMAN repeated that the Brush Company would pay all the expenses of the liquidation of the Company. They made it a strong point that one of the Directors of the Company should be a liquidator, and that they themselves should distribute the cash to the shareholders. He then put the motion, which was carried, there being only three dissentients. It would, he afterwards stated, be necessary to hold a confirmatory meeting, which would take place that day fortnight.

A vote of thanks to the Chairman brought the proceedings to a close.

Brush Midland Electric Light and Power Company.

The ordinary and extraordinary general meetings of the shareholders was held at the City Terminus Hotel, Cannon-street, on Tuesday; Mr. R. H. Glyn in the chair.

Mr. H. N. MYERS (the secretary) read the notice convening the ordinary meeting. The report and accounts were taken as read.

The CHAIRMAN said the shareholders were aware that two meetings had been convened; the first a merely formal one, to pass the accounts; the second a more important meeting, to consider the amalgamation of this Company with the Anglo-American Brush Corporation on the terms which had been submitted to the shareholders. He had very little to say with regard to the accounts, except to point out, as the shareholders had doubtless seen for themselves, that on the working of the year there had been a loss of about £1,000, although the expenses had been kept as low as possible. The only thing they could say was, that under the circumstances they were thankful that the loss was not larger. Unless the shareholders wished to ask any questions on the accounts he would suggest that they should be passed, and that they should then proceed to the business of the extraordinary meeting, to which he would refer more particularly. He formally moved the adoption of the report and accounts.

Mr. RUSSELL EVANS seconded the motion.

Mr. STOKES asked what was the position of the arrears of calls?

The CHAIRMAN replied that he would go into the matter at the extraordinary meeting.

A SHAREHOLDER said the shareholders agreed a year ago to give the Company a further trial, and unfortunately the trial had not proved successful. Under these circumstances he thought the Directors' fees and the salaries paid were too high.

The CHAIRMAN pointed out that under the Articles of Association the Directors were entitled to take £1,000 per annum; but they had only taken half that amount. The salaries had been kept as low as possible.

The motion was then put and carried unanimously.

The SECRETARY then read the notice convening the extraordinary meeting, which was called "for the purpose of considering, and, if approved, of confirming a provisional agreement made the 29th day of November, 1884, between this Company of the one part and the Anglo-American Brush Electric Light Corporation (Limited) of the other part, referred to in the report of the Directors of this date, and should such agreement be approved, for passing a special resolution for winding-up the affairs of this Company voluntarily, as the means of giving effect to the said agreement."

The CHAIRMAN said it would perhaps be advisable that at the outset the solicitor should state the effect of the provisional agreement into which the Directors had entered, subject to the approval of the shareholders.

Mr. GEORGE DAVIS (the solicitor) said the provisional agreement was dated the 29th November last, and was made between this Company and the Anglo-American Brush Electric Light Corporation (Limited). The first part of the agreement provided that the Midland Company should sell practically the whole of its assets to the Anglo-American Brush Corporation, and that as part of the consideration for that sale the purchasing corporation should satisfy all the obligations of the Midland Company; and there was this further consideration, that each member of the Midland Company should be entitled to acquire from the Anglo-American Brush Corporation at any time within six months of the date of the agreement four fully-paid up shares of £5 each of the Anglo-American Brush Corporation for every twenty-seven shares of £2 10s. each in the Midland Company held by him, and so in proportion for any less or the greater number; but every request for those shares must be in writing, signed by the party requiring the same, and countersigned by the liquidator of the Midland Company. The agreement went on to provide that in the event of any person not holding enough shares to entitle him to shares from the Anglo-American Brush Corporation, fractional certificates would be issued which could be dealt in on the market. There was a further provision that the sale was to take effect from that date, subject to the agreement being confirmed by the shareholders before the 24th inst. For the purpose of giving legal effect to this agreement, if approved, the Midland Company would have to go into voluntary liquidation.

The CHAIRMAN said: The solicitor having explained the legal effect of the agreement, the shareholders would probably want to know from the Directors what had induced them to adopt this plan. At the last meeting the shareholders were told that it was hoped the large amount of money which had been spent in advertising the Company very thoroughly would lead to some return hereafter, or, in fact, during the then ensuing year; but they had been unfortunate enough not to have realised those hopes. The fact of the matter was that the Company had only a very small capital and they were obliged to work in a small way. They had to try to get as many orders from people as they could to put up installations on

Digitized by Google

their own premises. for the Company had not the means to put up central stations, which, besides requiring a good deal of money to be spent, involved waiting a long time for results. They had found that a great number of people would have taken the light from them if they could have supplied it in the same way that a gas company would supply gas; but these people had not been willing to pay for separate installations on their own account, a fact which was not surprising in the present state of trade throughout the country. They had done some work, but as he had already stated, they had not been able to meet the expenses of the year out of the receipts. The directors had then to consider what should be done. To have attempted to raise fresh capital under the present circumstances would have been out of the question, and it then resolved itself into a question of liquidation or sale to another company. He had put himself into communication with Lord Thurlow, the chairman of the Anglo-American Brush Corporation, and after very full consideration and discussion, the provisional agreement which the solicitor had described had been entered into, subject to the approval of the shareholders, by which one £5 share in the Anglo-American Brush Corporation would be given for every 6¾ shares of £2 10s. each in the Midland Company. They would get in cash a little more, and in fact, value considerably more than if they liquidated without entering into this agreement. The Anglo-American Corporation would pay all the expenses of liquidation, and they would take over the installations on hire. These installations were worth something as a going concern; but if the Company went into liquidation pure and simple they would be worth very little indeed. Under all the circumstances the agreement was so favourable that he did not think the shareholders would hesitate for a moment in accepting it. The Board had gone into the matter very fully, and they were of opinion that the arrangement should be adopted in the interests of all concerned. He moved:—"That the provisional agreement submitted to this meeting, and made between this Company of the one part, and the Anglo-American Brush Electric Light Corporation (Limited), of the other part, be and the same is hereby approved and sanctioned."

Mr. JAMES PENDER seconded the motion.

A SHAREHOLDER said he was opposed to the agreement, and he preferred voluntary liquidation. If they went into liquidation they would get something, for they had £5,000 in hand, whereas by amalgamation with the parent company they would get nothing but uncertainty, with the probability of losing all.

The CHAIRMAN said he believed the Company would get more by amalgamating than by going into liquidation.

The SHAREHOLDER added that the shareholders were asked to accept shares in the parent Company, while those shares were going down and were likely to drop still lower. He contended that it would be better to take 4s. or 5s. a share than to accept a nominal price of 7s. 6d. a share from the parent Company, and he thought this Company should have been paid for advertising the Brush system instead of having to pay for concessions.

Mr. MATTHEW remarked that after their experience of the Anglo-merican Brush Corporation, which had sold for £43,000 a patent which it did not possess, he did not think the shareholders of this Company would wish to put themselves into the hands of that corporation, which had shown itself to be absolutely unreliable and untrustworthy. They had £5,000, and this would give them 10 per cent. on their holdings. He proposed as an amendment that the Company should go into voluntary liquidation, and that the winding-up should be carried out under the supervision of five of the shareholders, to be appointed at that meeting.

Mr. BURRIDGE seconded the amendment.

The CHAIRMAN said the shares which the shareholders would receive in exchange for their present holdings would be worth cash; and

Mr. HARRINGTON pointed out that Anglo-American Brush shares were not falling in price, as had been said; they had risen ten shillings within the last month.

Mr. HEWETT, as one of the largest shareholders in the Company, expressed his belief that the Directors had done their best to promote the interests of the shareholders, and he contended that it was better to accept the shares offered, which were £10 shares reduced to £5, than to go into liquidation with the hope of getting four shillings or five shillings a share.

The CHAIRMAN said the Board had an overwhelming number of proxies in favour of the agreement.

Mr. BURRIDGE thought the shareholders present ought to have a voice in the matter. He was certainly opposed to the amalgamation.

Mr. CHINNERY asked what it was estimated would be returned to the shareholders if they decided upon going into voluntary liquidation?

The CHAIRMAN said that, exclusive of the costs of liquidation, and apart from what the installations on hire might fetch, they would get about 8s. 10d. per share; but actually the net amount which the shareholders would receive would be about 6s. per share. Of course, if they divided the cash, they would have to include the Anglo-American Brush Corporation, which held about a fourth of the capital of this Company.

A SHAREHOLDER asked whether the present installations were paying?

The CHAIRMAN replied that they were about paying their expenses.

The amendment was then put and negatived, and the Chairman's motion was adopted by 11 to 4.

In reply to Mr. HARRINGTON the Chairman stated that the proxies in favour of the agreement represented more than half the voting power of the Company.

The CHAIRMAN then moved "That with the view of carrying into effect the agreement between this Company and the Anglo-American Brush Electric Light Corporation (Limited) submitted to and approved at the extraordinary general meeting of the Company held this day, the Company be wound up voluntarily under the provisions of the Companies Acts."

Mr. JAMES PENDER seconded the motion, and it was adopted.

The meeting then closed.

The Oriental Telephone Company.

The following notice to the shareholders has been issued by the Directors of the Company:—

The Directors think it necessary again to urge each individual shareholder carefully to consider his position in this undertaking, and if possible to attend the meeting. If unable to do so, he should well weigh all the circumstances before giving his proxy to be used against the Board. Shareholders will have received a circular, signed by Mr. Thomas Lloyd, written in the interests of those who have called the meeting. The only point raised in that circular which has not been already anticipated by the Board in their circular of 29th ultimo refers to the relations of the fully paid-up shares to the part paid-up shares. In order that the proprietors may not be deceived on this point, they are reminded that the holders of fully paid-up shares cannot benefit, in any way, until the part paid shares have received cumulative dividends to the aggregate amount of 30 per cent. Hence it must obviously follow that the holders of fully paid-up shares are even more interested than are the holders of part paid shares that the capital called up on the latter shall be kept down to the lowest possible figure. The Directors cannot pass over the unworthy suggestion of an intention on their part of allowing the Company to drift into a liquidation, so as to benefit the holders of fully paid-up shares. It ought not to be necessary to say that there is nothing in the position to justify such a suggestion. Shareholders must, however, themselves judge, whether the present agitation is the best mode of avoiding the liquidation which Mr. Lloyd appears so much to fear. Not only have the Directors voluntarily placed at the disposal of the shareholders all the records of the Company, but they have frequently expressed their willingness to admit into their counsels one or two large shareholders who might care to join the Board; but this proposition has not been accepted. It is obviously impossible for the present Directors to remain on a Board which, if added to in the hostile manner proposed by the resolution, would of necessity force them into the position of mere dummies. For the rest, Mr. Lloyd's circular refers to the connection of certain members of the Board with another company. It is not too much to ask that members of this Company shall not allow themselves to be prejudiced by such allusions without first informing themselves fully upon both sides of the matters referred to.

NOTES.

CHRISTMAS WEEK.—*The Electrician* will be published on Wednesday instead of Friday.

THE BENNETT-MACKAY CABLES.—It is reported that these cables are now in working order.

TELEGRAMS FOR BRITISH GUIANA.—The cable between Trinidad and Demerara is interrupted.

VIENNA ELECTRICAL EXHIBITION.—The official returns show that the receipts amounted to 350,800fl. (about £35,080), the number of visitors being 881,000.

ELECTRICAL EXHIBITION IN VIENNA.—A permanent exhibition of electrical apparatus is announced to open shortly in the middle of the city, where the various instruments shown may be experimented with.

PRESIDENT OF THE TELEGRAPH ENGINEERS.—Mr. C. E. Spagnoletti, of the Great Western Rallway, has been elected president of the Society of Telegraph-Engineers and Electricians for the ensuing year.

A DRAMATIC ELECTRICIAN.—Dr. Harry Lobb, the elec trician, has written a new idyllic and lyric one-act play, "Sappho," which will be played for the first time at a Lyceum *matinée* early in the new year.

BERLIN TELEGRAPH CONFERENCE.—This Conference is announced to open on 10th August, 1885. Official invitations will be sent to the Governments of all the countries which took part in the St. Petersburg Confederation.

STORAGE CELLS.—In our note last week on the above subject, the useful capacity of the Electrical Power Storage Company's cells exhibited was stated to be 100 ampere-hours, instead of 300, which, we are informed, is the useful output of the size in question.

THE TELEPHONE IN RIO JANEIRO.—After two years' hard competition, the two telephone companies—the Companhia Telephonica and the Companhia de Telegrafos Urbanos—the former with 300 and the latter with 750 subscribers—have agreed to an amalgamation.

PERSONAL.—The Globe Electrical and Engineering Company, under the management of Mr. Walter D'Alton, M.I.M.E., has taken over the manufacture of Mr. Killingworth Hedges' fusible safety catches or cut-outs, and has opened offices at 20, Dartmouth-street, Westminster.

WAX VERSUS ELECTRIC LIGHT.—The *Daily Telegraph's* Vienna correspondent telegraphs that the hardly credible report comes from Rome that the Pope has forbidden the use of electric light in Catholic churches. Do wax candles give a purer, healthier, cleaner light, or is gas preferred?

APPOINTMENT.—Messrs. Tasker, Sons, and Co., of Sheffield, have received from the Lord Chamberlain the appointment of telephone engineers to Her Majesty, in recognition of the satisfactory nature of the telephone work recently done by them at Balmoral, Abergeldie, Ballater, and Windsor.

ELECTRIC LIGHT AT ANTWERP.—The Brussels Compagnie Générale d'Electricité has been authorised by the Antwerp Municipality to light the eastern quarter of the city (that near the State Railway Station), including the Avenue de Keyser. The installation is expected to be complete by 12th February of next year.

ELECTRIC LIGHT FOR LECTURES.—On the occasion of the popular lectures given recently by Mr. Eric Bruce, at the Crystal Palace, Kensington Assembly Rooms, Grosvenor Hall, and other places, the stage was lit by means of the Electrical Power Storage Company's cells, which also furnished the current for the experiments.

ELECTRIC LIGHT FOR REGENT-STREET.—On Monday the lighting committee of St. James's, Westminster, consisting of Mr. E. C. Keevil, Mr. N. Jenkins, Mr. C. Lewis, and Mr. J. Bonthron, visited the dynamo works at Greenwich, and the electric lighting station at Paddington, with a view to examine the system and apply the same to Regent-street and Piccadilly.

ELECTRIC LIGHT AT COLLIERIES.—The pit heap at Burradon, Northumberland, is now illuminated by the electric light, arc lamps having been placed at various points. Shed on the screens in particular, a flood of light enabled the screeners to perform their labour with comparative ease. The power is obtained from a small engine, placed in the engine room connected with the pit.

CAB, FIRE, AND POLICE CALLS.—It is proposed to establish in London a system of "cab call and police and fire communications," by means of a dial placed in the hall of a subscriber's house, another at the nearest rank, a third at the fire brigade depot, and a fourth at the police station. Capt. Shaw has reported favourably of the scheme, and a company has been formed to work it.

THE TELEPHONE IN COLUMBO.—A telephone concession has been granted to José R. Martinez, who has handed it over to the Companhia Colombiana de Telefonos, of which he remains the general manager. The wires are overhead; and conversation may be carried on day and night, there being communication with the fire and police stations. The subscription is £1 per month or £12 per annum.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The directors of this company have declared an interim dividend of 3s. per share, or 6 per cent. per annum, free of income tax, for the quarter ending 30th September, and payable on the 24th December. The books of this company will be closed from the 17th to 23rd December, both days inclusive. The traffic receipts of the company for the week ended 12th inst. amounted to £3,880.

ELECTRIC LIGHT AT BELFAST.—On Tuesday at a meeting of the Belfast Harbour Commissioners, Mr. John Greenhill moved that they should ask three or four of the leading electric light companies to give an estimate as to the illumination of the sheds and quays by the electric light for three or five years, the company to supply all appliances. Mr. W. C. Mitchell seconded the resolution; but it was lost, the mover and seconder only voting in its favour.

THE CREIL EXPERIMENTS.—The *Bulletin* of the Compagnie Internationale des Téléphones states that, thanks to the experience acquired in mounting the first generator, the second is, according to the Creil engineers, put down under much better conditions of working, as regards the suppression of passive resistance. In addition to the transmission of power, M. Marcel Deprez intends, in conjunction with Dr. Hertz, to conduct, at Creil, experiments in long-distance telephony.

ELECTRIC LIGHT IN PARIS.—Burrington, jeweller, in the Rue Castiglione, Paris, has placed a small incandescent lamp in each of his four glass cases, which were too small to admit a gas flame. The lamps are fed by four 6-element bichromate of potash batteries, the exciting liquid of which has to be changed every morning. Prat and Victor, Rue de Moscou, have placed two incandescent lamps in their office, and four outside the house, maintained by Trouvé bichromate batteries.

THE TELEPHONE IN MONTEVIDEO.—The Compania Telefonica, La Uruguaya, now under the control of Messrs. J. K.

Digitized by Google

Theobald and Co., of Buenos Ayres and Montevideo, which has in use over 700 Bell telephones in Montevideo, has given an order for 300 more to the United Telephone Company, River Plate. The United Company supplied at once 100 from a shipment arriving on 5th inst. by the "Malabar," and cabled for the remainder. La Uruguaya company expects to have 1,000 subscribers in Montevideo.

DOMESTIC ELECTRICAL POWER.—The generating machines of the Compagnie Electrique may be used both for light and power. M. Daguin has put one down, at a leading Paris restaurant, for driving knife-cleaners, bottle-washers and floor-polishers during the day, and causing the carbon filaments of the lamps to glow in the evening.—A company, called "Le Chrôme," has been formed in Paris for supplying and maintaining, by contract, special chromic acid batteries, for lighting and various domestic applications.

BON MARCHE INSTALLATION.—This title must not be read literally, because it would convey just the wrong signification. We refer to the electric light installation at the large drapery establishment known as the Bon Marché, in Paris. As long as the current was supplied by dynamos, all went well; but the directors refused to allow them on the premises, so bichromate of potash batteries were tried instead. These made too great demands upon the purse; and now—can one believe it?—gas is re-instated at the Bon Marché.

GAULARD AND GIBBS.—It appears from a letter by Signor Ferrini to the *Lumière Electrique* that the 90 per cent. of work recorded at Turin, was obtained by measuring the intensity of the primary and secondary currents with two Siemens electro-dynamometers, previously compared with one another, and the differences of potential at the respective terminals with two Mascart electrometers. It is, therefore, not the useful effect, that is to say, the ratio of energy expended to energy recovered, but simply a co-efficient of transformation proper to the apparatus.

TELEPHONE SUBSCRIPTIONS.—According to *L'Electricité*, the following are the rates of subscription to the telephone exchanges in the following European cities and countries:—London, £20; Paris, £24; Riga and Odessa, £25; Austria, £9 to £15; Germany, from £10, with an increase of £2 2s. for every kilometre (1·24 mile) over two; Italy, varying from £4 12s. to £7, with the towns; Norway, £4 to £8, according to distance; Sweden, £6 8s. to £10 16s; Holland, £10; Portugal, £15 for traders and £7 for private individuals; Switzerland, £4 to £10.

THE TELEPHONE IN VIENNA.—By the end of June last the Vienna telephone lines attained a length of 175 kilometres (108 miles). The total length of wire in the cables was 1,300 kilometres (807 miles), and in underground lines, of silicon bronze wire 1mm. in diameter, 1,683 kilometres (1,045 miles.) The number of subscribers was 708, and that of direct connections 120. In the month of June nearly 52,500 messages were sent by the subscribers, making 1,750 a day. The two central offices, which open at 7 o'clock in summer and 8 o'clock in winter, closing at 9 o'clock, are served by 42 girls.

THE TELEPHONE IN PARIS—It is rumoured that the Société des Téléphones is trying to obtain from the Paris Municipal College a reduction from the rent charged on telephone lines, and also a continuation of the permission to fix wires in the sewers instead of overhead, while holding out the hope of giving increased facilities to the public in the shape of "call" offices. The French Minister of Posts and Telegraphs, while recently prolonging for five years the present concession of the company, stated that he would not refuse a similar concession to a competing company offering adequate guarantees.

COMMUNICATION BETWEEN ENGLAND AND BRITISH NORTH BORNEO.—Speaking at the half-yearly meeting, on Wednesday, of the shareholders in the British North Borneo Company, Sir Rutherford Alcock, alluding to the progress of the colony, said that he did not even despair of their territory being put in telegraphic communication with England before any long time elapsed. There was, indeed, some chance of it now, as the question was under consideration of a duplicate line from Manilla and Hong Kong. It would be a great gain to them to have telegraphic communication with this country.

UNDERGROUND WIRES IN PHILADELPHIA.—The Western Union Company has made an arrangement for running wires underground with Mr. David Brooks, who says:—"The company agrees to use 100 wires in the cable, which I will lay down for a term of seven years with the privilege of renewing at the end of that time. The trunk line of the cable will be on Broad-street; and the cables will run from the Broad-street Station to Third and Chestnut-streets, where the Western Union people expect to establish their main office. Another cable will be run to Tenth and Chestnut-streets, and one from there to the Kensington Station."

NEW ORLEANS EXHIBITION.—The opening of this Exhibition, covering 60 acres, took place on Tuesday last, amid great enthusiasm. Telegraphic communication was established between the building and the White House at Washington, where President Arthur had assembled the members of the Cabinet, the presiding officers of both Houses of Congress, the members of the Diplomatic Corps, and the judges of the Supreme Court. A telegraph instrument brought intelligence into the room that all was ready, when the President formally declared the Exposition opened; and the message was received at New Orleans a moment later. The engine for driving the machinery then started, and the pullies began to revolve. It is expected that the Exhibition will be completed in a week's time, and that it will be equal in importance to that of Philadelphia.

INTERNATIONAL INVENTIONS EXHIBITION.—With a view to giving further protection to the inventions of exhibitors, a new certificate has been granted by the Board of Trade to the effect that "the International Inventions Exhibition proposed to be held at South Kensington, in the county of Middlesex, from the 1st day of March, 1885, is an International Exhibition;" and by this means all the protection, accorded from the 1st of May to inventions under the original certificate (dated the 15th of August), will be secured in addition from the 1st of March till the 1st of May—namely, during the time in which the exhibits will be received and arranged. A printed copy of the extracts from the "Patents, Designs, and Trade Marks Act, 1883," bearing on this subject, may be obtained on application to the Secretary, International Inventions Exhibition, South Kensington, S.W.

SIXPENNY TELEGRAMS.—In view of the greater influx of messages which may be anticipated in consequence of the adoption of the cheaper rate of telegraphing in August next, the Electrical Department of the Post Office is adding a large number of new wires throughout the metropolis and the provinces. In London, notably in the Paddington district, along the Uxbridge-road and other main thoroughfares, the wires have been placed in iron piping underground, it being the intention of the authorities to do away as far as practicable with all overhead wires; and the pneumatic tubing now so

Digitized by Google

successfully worked between the London Central Telegraph Office and the City offices will, it is anticipated, be extended to the various district offices throughout the metropolis, thus enabling the department to turn the wires in present use at these offices, about twelve in all, to another account.

ELECTRICAL VERIFICATION OF DEATH.—This subject has been revived by Dr. Buch, who finds that, in the living subject, the temperature rises appreciably at the surface of the muscle subjected to the action of an electric current, and also that this increase of temperature never occurs in a corpse, under similar circumstances, even during a few hours after death. He uses an ordinary mercurial thermometer, which is simply applied to the surface of the skin, waits until the height of the mercury remains constant, and then submits the subjacent muscle to an induced current, when the temperature of the skin increases several degrees under the influence of energetic contraction. This phenomenon is constant in living persons, even in the case of total paralysis; but, in the case of a corpse, the mercury remains stationary, notwithstanding the force of the current and the violence of the contraction.

TRADE AND THE TELEGRAPH.—In the course of remarks in his address, on the evening of the 17th inst., before the Institute of Bankers "On the Prices of Some Commodities during the Decade 1874-83," Mr. Luke Hansard stated that the more extended use of the telegraph had had the tendency of making over-supply more prominent. In the various channels of distribution less stock was required than formerly, from the retailer upwards, owing to the rapid manner in which supplies can be ordered. The large manufacturer was not now under the same necessity of keeping stock by him as formerly. "The telegraph," continued Mr. Hansard, "has enabled the merchant or wholesale dealer to make more frequent use of the markets abroad, and from the rapid increase both in the speed and number of steamers he can have his orders executed in an incredibly short space of time, compared with 10 years ago. From the less time the stock is on hand there is less uncertainty in any venture, and traders can carry on business with smaller capital than formerly, with the effect of squeezing out the middleman and further lessening the cost of distribution."

INCANDESCENT INSTALLATION NEAR PARIS.—We learn from *L'Electricité* that an interesting application of the incandescent light has been made to the colour works of MM. Sordes et Huillard, at Suresnes, near Paris, to the extinction of about 800 gas flames. Current for the hundred and thirty-odd lamps is supplied by an Edison dynamo, which, at a speed of 1,050 revolutions a minute, gives out 110 volts at 90 amperes, while absorbing 16 horse-power from one of the works' engines, the steam for which is obtained from a large boiler used to heat the pans. The dynamo and switch-board are placed in a building where the workmen are forbidden to enter; and the extreme points of the circuit are about 150 yards apart. Those lamps which light the pans that are filled with steam are inserted in paraffined sockets, which stand the damp atmosphere. The two residences of the partners, which are near the works, are connected therewith by a special circuit, and provided with incandescent lamps on all the floors. As the dynamo is kept running day and night, light may be obtained at any time. The yearly expenses are stated to be 7,930f. (£317), including interest on capital and sinking fund, while gas for the previous year cost 11,800f. (£432).

KEEPING MILK BY ELECTRICITY.—Our readers will remember the conversation, attributed to Edison by a recent interviewer and reproduced in these columns, as to the effect of electric current in "aging" whisky. Another and more generally useful application of the subtle influence, that of keeping milk sweet, has been communicated by a correspondent to the *Standard* as follows:—"In reference to the London milk supply from Holland and the keeping of milk sweet, by icing or other means, I may mention that I repeatedly saw the late Mr. Andrew Crosse, in his laboratory at Fyne Court, make experiments in subjecting milk to electric action, whereby it was kept sweet for weeks together. In the 'Memorials of Andrew Crosse,' p. 219, the very simple arrangement is described:—'Two cylinders of sheet zinc and sheet iron are severally placed in two porous earthenware tubes, open at the top, closed at the bottom, the same being filled with water . . . . and connected at the top by a copper riband. . . . The earthenware vessels are placed in the fluid (milk or other), the electrical action immediately commences, and the fluid becomes antiseptic in a few hours,' p. 221. 'Milk has been kept sweet for three weeks by this process in the middle of summer.'"

GREAT WESTERN ELECTRIC LIGHT COMPANY.—Notice is given that an extraordinary general meeting of this company will be held at the offices, 4, Great Winchester-street, on Tuesday, the 23rd inst. at noon, for the purpose of considering and, if deemed advisable, of confirming as special resolutions the following resolutions, which were passed at the extraordinary general meeting held on the 8th inst., viz.:—1. That the conditional agreement submitted to this meeting, and made between this Company of the one part, and the Anglo-American Brush Electric Light Corporation, of the other part, be, and the same is hereby approved and sanctioned. 2. That with a view to carrying the said conditional agreement into effect, the Company be wound up voluntarily, and that Mr. Emile Garcke and Mr. F. W. Reynolds be, and they are hereby appointed liquidators for the purpose of such winding up. 3. That pursuant to the Companies Act, 1862, the said liquidators be, and they are hereby authorised and directed to adopt, on behalf of this Company, the said agreement, and to receive paid-up shares in the said Corporation, as consideration for the property thereby agreed to be sold in accordance with the terms of such agreement, and generally to carry the same into effect.

AN ELECTRICALLY-WORKED CRANE.—We learn from the *Bulletin* of the Cie Internationale des Téléphones that, during last month, a 20-ton crane, the motions of which are given by the electric current, has worked in the foundry of M. Farcot, at Saint-Ouen. The generating machine, placed rather over 100 yards from the crane, gives a current at the terminals of about 350 volts at 13 amperes when making 1,550 revolutions a minute. The receiving apparatus, attached to the crane, makes 1,000 revolutions a minute, and exerts a power of four horses at its shaft. A special rheostat permits of progressively introducing resistances which may amount to 60 ohms, and, consequently, of varying at will the speed of lift. No change has been made in the parts of the crane, which may be worked by hand when the steam-engine is not running. A Mégy brake, made by Sautter et Lemonnier, would prevent the load from falling in the event of any accidental derangement. In lifting heavy castings from their moulds, a vacuum is caused, owing to which the total or partial atmospheric pressure is added to their weight, which might thus exceed the power of the crane. In such a case, the circuit is interrupted automatically, thus warning the engine-man. By the aid of the electric current one man now works the crane instead of ten as formerly.

NATIONAL TELEPHONE COMPANY.—This company has issued a new list of subscribers in the Glasgow district for the month

Digitized by Google

of December. The first telephone was installed at Glasgow in October, 1879; and there are now in operation over 900 exchange and 300 private lines. The subscribers now number about a thousand; and additions are being made daily. A good thing for Glasgow is that there is now only one exchange system, all the other telephone interests having been amalgamated in the National Telephone Company. The company offers its subscribers either private wires for exclusive communication between two or more fixed points, or wires connected with the nearest exchange—the latter affording direct communication with every subscriber to the exchange system. The objection of principals to being called and asked questions which can be answered by their clerks, or having to talk in the hearing of others, is met by arranging one set of instruments in the clerks' and another in the principal's office. The company is also prepared to lay down temporary lines for special purposes, for instance between the offices of engineers, architects or contractors and the works they are superintending or carrying out. The exchanges are open day and night; and ten call boxes are established for the use of subscribers, while a corps of commissionaires has been organised in connection. Besides the Fire Brigade Depot, the St. Andrew's Ambulance Association and the Royal and Western Infirmaries are put in communication.

NEWCASTLE-ON-TYNE.—The Trustees of the Fund resulting from the North-East Coast Exhibition of Naval Architecture and Engineering, held at Tynemouth in 1882, have applied the surplus proceeds of the Exhibition to the foundation of a scholarship, of the annual value of £30, tenable for two years, at the Durham College of Science, Newcastle-upon-Tyne, to be called the North-East Coast Naval Architecture and Engineering Exhibition. The College, in accepting the offer of the Trustees, has agreed to remit the whole of the fees in the case of the holder of the exhibition, so that the actual value of the scholarship will be about £60 per annum. Candidates must be apprentices or workmen engaged in one of the shipbuilding or engineering establishments in the district of the Tyne, Wear, or Tees. The exhibition will be awarded on the result of a competitive examination in elementary mathematics, pure and applied mechanics, physics, and inorganic chemistry; and the exhibitioner will, in the first instance, be elected for one year, but will continue to hold the exhibition for a second year if his progress be satisfactory. The first examination will commence on Thursday, 15th January, 1885, and candidates must send their names to the Secretary of the Durham College of Science on or before Saturday, January 10th. It is expected that before long a chair of naval architecture and marine engineering will be founded at the Durham College of Science; and in the new buildings of the college special provision will be made for experimental work in connection with this chair.

BRITISH ASSOCIATION.—At the close of the British Association Meeting at Montreal, the suggestion was brought forward that, in commemoration of the meeting, and as a recognition of the hospitality with which the members of the Association had been treated in Canada, it would be a graceful act to form a fund for the purpose af founding a gold medal at the McGill University at Montreal. After consultation with the authorities of the university, it was agreed that, subject to further consideration, the medal should be given annually, in the Faculty of Applied Science, in which there is at present no prize of this sort. Lord Rayleigh, the president of the association, undertook to act as treasurer, and Mr. W. Topley and Mr. H. Trueman Wood as honorary secretaries. In answer to an appeal circulated amongst the members in Canada, and to a circular which has been issued in this country since the return of the association, a sum amounting at present to £540 has been subscribed. Deducting the necessary expenses of printing and postage, there will remain an amount of something over £500 to provide the medal. The general committee of the association have agreed to provide from its funds sufficient for the purchase of a die, so that the interest resulting annually from the investment of the whole of the above amount may be available for the medal itself. The honorary secretaries will be glad to receive contributions from any members of the association who may not yet have subscribed. These may be sent to them at the Society of Arts' house, John-street, Adelphi; or may be paid into the account of the fund, at Messrs. Hoare's, 37, Fleet-street.

"THE MONTHLY CORRESPONDENT."—This is the title of a little monthly magazine, dedicated to the staff of the Brazilian Submarine Telegraph Company, and issued at Madeira. It was started a year ago by Mr. E. B. Barker, clerk-in-charge, with the object of affording information on subjects of general or particular interest to the company's staffs at the various stations; and an appeal was made to members of the profession to contribute articles connected with the theoretical and practical aspect of telegraphy. Considering the great difficulties in the way of such an undertaking, the *Monthly Correspondent* has made a very respectable show during the twelve months of its existence; and, as this is the season of good wishes, we hope it may live long and prosper with a progressively increasing circulation. It is difficult to estimate the value of such a publication in a little centre of Englishmen away from home. It creates interest in the daily work, and promotes *esprit de corps*, besides giving technical information that is more likely to be read and digested in such a form than in a large treatise. Telegraph clerks are, as a rule, too apt to be content with mere routine, without lifting their nose from the instrument. But if they would only magnify their office, and inquire into the why and wherefore of what they do, they would be fitting themselves for seizing hold of that chance which comes to every man at least once in his life. For instance, the clerk who, besides being a rapid and correct operator, has made himself acquainted with the engineering and electrical details of the instruments, might, on a hitch occurring, find himself able to set it right, and so save the delay and expense of sending an electrician out from England. Such a man would decidedly wear a feather in his cap, and be marked for promotion on a vacancy occurring.

DOMESTIC LIGHTING.—On Monday evening Mr. Robert Hammond, managing director, Hammond Electric Light and Power Supply Company (Limited), received a succession of visitors to inspect the arrangements for lighting his residence at Highgate. The installation has been down nearly three years, and is considered to be gradually paying off its first cost by the saving effected in renewals of paint, wall-paper, and decoration generally. The engine room is erected in the garden, and provided with an 8 horse-power Otto gas engine, in which an explosion takes place every other stroke. This engine makes rather over 150 revolutions a minute, and drives a Ferranti alternating-current dynamo at about 1,000 a minute, excited by a small direct-current Siemens machine. A resistance frame with German silver wires is interposed in the circuit, because the power and generating capacity are in excess of present requirements; so that Mr. Hammond is in a position to lend a little current to a neighbour on the occasion of a ball or *soirée*, or, indeed, to permanently light a neighbour's premises, without the exercise of any self-abnega-

Digitized by Google

tion in this respect. We heard that there were in all 71 Swan lamps of 20 candle-power nominal, disposed about the premises, and were permitted access to the *penetralia* in order to count them. This number includes four in the engine room, one in the wine cellar, another in the scullery, two in the kitchen, with one naked movable lamp for inspecting the culinary operations, and others in bed rooms, dressing rooms, lavatory, and w.c.'s; in fact, there is no gas whatever about the premises. In the drawing rooms, nine lamps with appropriate shades are placed in the middle of movable shields hung round the walls, while three lamps are pendent from the ceiling and another is placed on a movable reading standard. In the dining room, what is called on the Continent a "suspension," or porcelaine dome suspended from the ceiling, has three naked lamps inside, while eight with shades are disposed round the circumference. These may be regulated, by means of a resistance coil, so as to give any desired amount of intensity. Mr. Hammond has a switch at the side of his bed, by which he can break contact, and allow a weighted sluice-valve to fall, thus shutting off the gas from the engine, and putting out the lamps. No electrician or engine driver is employed; but the gardener starts the gas engine and then leaves the plant to take care of itself. In our note last week of the *conversazione* at the Hammond Electrical College, we mistook for Mr. Phillips, the electrical engineer, who was unavoidably absent, Mr. F. R. Barrett, B.A., B.Sc., the mathematical lecturer, who showed some of the electrical apparatus.

COMMUNICATION BETWEEN THE SHORE AND LIGHT SHIPS.—It often happens that a vessel is lost after battling with the sea for several hours in sight of a light ship, and might have been saved if a message could have been sent on shore. But the difficulties in the way of affording such communication have hitherto been regarded as practically insurmountable. They originate mainly in the constant and excessive motion of the light ships, which are moored at the bow by a chain cable 4½in. in circumference, "payed" out sufficiently in rough weather to allow them to ride and swing freely. In this way they often describe a complete circle; and, to prevent the telegraphic cable from being fouled by the moorings, if separate from the latter, especially as it would have to be similarly "payed" out to keep it from parting, has been the main problem. Another danger to be guarded against was that of damage to the telegraphic cable by ships' anchors, light-vessels being generally moored in shallow waters. A year or two ago, however, the whole matter was placed in the hands of the Telegraph Construction and Maintenance Company (Limited); and a contract was entered into whereby, as a practical experiment, they were to electrically connect the "Sunk" light-vessel with Walton-on-the-Naze, and maintain such communication for one year, no payment being made in the event of any failure to comply with the conditions, unless such failure should arise during the working of the cable from exceptional causes for which the contractors could not fairly be held responsible. The first part of this contract has now been fulfilled, considerable delay having previously occurred, owing to the necessity for several series of experiments at the company's works and elsewhere. It was foreseen at the outset that, to guard against the dangers already indicated, the telegraphic cable must be enclosed within the ship's moorings; and to determine the best form of the latter the experiments in question were undertaken. Ultimately it was resolved to adopt a hollow steel wire rope, 8½ inches in circumference, formed by fourteen twisted strands; and this rope—capable of bearing a tensile strain of 70 tons, and having the telegraphic cable running through its centre—constitutes the present ship's mooring, in lieu of the chain of 4½ inch circumference previously employed. On the 3rd inst. the contractors commenced the operation of laying the cable and moorings. Owing, however, to strong south-westerly winds, little could be done for several days beyond fixing the telegraph instruments, consisting of a Morse transmitter, a Wheatstone A.B.C., and a telephone on board the light vessel, and also at Walton-on-the-Naze, and laying the shore end of the cable at the latter place; but on the 7th and 8th inst. the entire work was accomplished with a success which promises well for its future working. This light ship, moored in ten fathoms at low water, is about nine miles from Walton-on-the-Naze. The cable passes under the public road to the post office at that place, which office is in direct communication *vid* Colchester with Harwich, from whence the various lifeboat stations along the coast are easily accessible by telegraph.

ELECTRIC LIGHTING ACT.—The following is a list of the members of the General Committee, formed on the suggestion of the President of the Board of Trade, to frame clauses in amendment of the Electric Lighting Act, 1882, and to confer with the Board of Trade as to the terms of the provisional orders and licenses:—

The Right Hon. Lord Thurlow, Chairman of the Anglo-American Brush Electric Light Corporation.
The Viscount Anson.
Sir F. Abel, K.C.B., F.R.S.
Sir F. J. Bramwell, F.R.S.
Sir Charles Bright, M.I.C.E., Vice-President of the Society of Telegraph Engineers and Electricians.
Sir Daniel Cooper, Bart., K.C.M.G., Chairman of the Electrical Power Storage Company.
Sir Rawson W. Rawson, K.C.M.G., C.B., Chairman of the Pilsen-Joel and General Electric Light Company.
Sir David Salomons, Bart.
Sir Wm. Thomson, F.R.S., LL.D.
Sir C. L. Young, Bart., Chairman of the Hammond Electric Light and Power Supply Company.
Professor W. E. Ayrton, F.R.S.
J. B. Braithwaite, jun., Esq., Managing Director Great Western Electric Light and Power Company.
R. Campbell, Esq.
Latimer Clark, Esq., M.I.C.E.
Henry Cunynghame, Esq., Author of "The Law of Electric Lighting."
J. Irving Courtenay, Esq.
R. E. Crompton, Esq., of Messrs. R. E. Crompton and Co.
Professor W. Crookes, F.R.S.
Professor Ewing.
Professor G. Forbes, M.A., F.R.S.E.
James Staats Forbes, Esq., Chairman Edison and Swan United Electric Light Company.
Captain Douglas Galton, C.B., F.R.S.
Herbert C. Gibbs, Esq.
J. Dixon Gibbs, Esq., Director the National Company for the Distribution of Electricity by Secondary Generators.
R. Hammond, Esq., Managing Director of the Hammond Electric Light and Power Supply Company.
F. Ince, Esq., of Messrs. Ingledew and Ince, Solicitors.
Professor A. Jamieson, C.E., F.R.S.E.
Professor Fleeming Jenkin, LL.D., F.R.S.
W. H. Massey, Esq., M.S.T.E.
William Ladd, Esq.
George Offor, Esq., General Manager South Eastern and Provincial Brush Electric Light and Power Companies.
Major S. Flood Page, Secretary Edison and Swan United Electric Light Company.
A. Renshaw, Esq., of Messrs. Renshaw, Solicitors.
J. S. Sellon, Esq., Vice-Chairman Anglo-American Brush Electric Light Corporation.
Colonel F. G. Steuart.
J. W. Swan, Esq.
Professor Silvanus P. Thompson, B.A., D.Sc., M.S.T.E.
Hugh Watt, Esq., Managing Director Maxim-Weston Electric Company.
E. Woods, Esq., Vice-President of the Institution of Civil Engineers.
Frank Wynne, Esq., General Manager Anglo-American Brush Electric Light Corporation.

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 49.

Dissimilar Coils. Characteristic Function of a Linear System of Conductors.

As might be expected, when, in the combination as specified in the last section, the coils and cores are made dissimilar in their dimensions and materials, it is no longer possible to express the general solution in terms of two comparatively simple solutions, although with special relations amongst the coil data it may sometimes be expressed in terms of a limited number of simpler solutions. Now, so far as the mere algebra goes we can easily arrive at the general solution when the coils are dissimilar, and in fact more easily than when there are particular relations introducing indeterminateness in the general solution, requiring special attention; but, owing to difficulties of interpretation, the general solution has very limited utility, except in showing how we might, if we gave the time to it, completely solve the problem numerically. But there are, on the journey to the general solution, some views by the way which make it more interesting and instructive than it would otherwise be, and it is to exhibit them, rather than a mere mathematical complication, that the present section is written, before leaving coils in combination and proceeding to other parts of the subject of induction in cores and elsewhere.

Starting, in the first place, with a linear system of conductors, self-contained, that is, having no connection with other conductors, let there be q points connected by $\frac{1}{2}q\,(q+1)$ conductors, the least number that will join every point with all the rest. Let their potentials be $P_1, P_2, \ldots$. To distinguish the different conductors, use double suffixes. Thus, let K_{12} be the conductivity (reciprocal of resistance) of the conductor joining the points 1 and 2, and Γ_{12} the current from 1 to 2, with a similar notation for the rest.

Continuity of current requires that the sum of the currents leaving any point shall vanish. Thus, for point 1, we have

$$\Gamma_{12}+\Gamma_{13}+\Gamma_{14}+\ldots+\Gamma_{1q}=0, \quad . \quad . \quad . \quad (124)$$

There are $q-1$ other equations of this kind, got by changing the first suffixes.

Next, let E_{12} be the impressed force from 1 to 2, and similarly for the other conductors; then, by Ohm's law,

$$\Gamma_{12}=K_{12}(E_{12}+P_1-P_2) \quad . \quad . \quad . \quad . \quad (125)$$

expresses the current in the branch joining the points 1 and 2 in terms of the impressed force in that branch and the potentials at its ends. There are $\frac{1}{2}q\,(q+1)$ equations of this kind. Insert in (124), and we have

$$(K_{12}E_{12}+K_{13}E_{13}+\ldots+K_{1q}E_{1q})+(K_{12}+\ldots+K_{1q})P_1 = (K_{12}P_2+K_{13}P_3+\ldots+K_{1q}P_q) \quad . \quad . \quad . \quad . \quad . \quad (126),$$

with $q-1$ other equations of the same kind. Here the quantity in the first ( ) is the current that would leave the point 1 by all the conductors meeting there if the impressed forces were the only forces; call it C_1, and similarly for the other points. Also, put

$$-K_{11}=K_{12}+K_{13}+\ldots+K_{1q} \quad . \quad . \quad . \quad (127)$$

and we get

$$\left.\begin{aligned} C_1&=K_{11}P_1+K_{12}P_2+K_{13}P_3+\ldots+K_{1q}P_q\\ C_2&=K_{21}P_1+K_{22}P_2+K_{23}P_3+\ldots+K_{2q}P_q\\ &\ldots\ldots\ldots\ldots\ldots\ldots\\ C_q&=K_{q1}P_1+K_{q2}P_2+\ldots\qquad\qquad+K_{qq}P_q \end{aligned}\right\} \quad . \quad (128)$$

Here, as we have q linear equations and q potentials, it looks as if we could find them. Thus, if K is the determinant of the K's, and Z_{rs} the coefficient of K_{rs} in this determinant, so that

$$K=K_{11}Z_{11}+K_{12}Z_{12}+\ldots+K_{1q}Z_{1q} \quad . \quad . \quad (129)$$

and similar expressions, we should have

$$KP_1=C_1Z_{11}+C_2Z_{21}+\ldots+C_qZ_{q1} \quad . \quad . \quad (130)$$

and similar expressions for the other potentials. But K_{11}, $K_{22}, \ldots$, are not independent of the other real K's, being defined by (127). This structure of the diagonal K's makes all the Z's identical, and the sum of the K's in any one row or column of (128) to vanish, so that if Z is the common value of the Z's, (129) becomes

$$K=(K_{11}+K_{12}+\ldots+K_{1q})Z=0\times Z,$$

by (127), and (130) becomes

$$0\times P_1=(\Sigma C)Z=0\times Z,$$

since the sum of the C's also vanishes. We cannot find the q potentials, but only $q-1$ of them, supposing the remaining one to be given.

Maxwell's investigation, Vol. I., Art. 280, differs from the above in the system not being self-contained, having external connections at the q points, at which there are given currents $Q_1, Q_2, \ldots$, entering the system. This only requires us to write C_1-Q_1 instead of C_1, C_2-Q_2 for C_2, &c. in (128). But regarding the fact that only $q-1$ equations are independent, Maxwell ascribes it to the necessary condition $\Sigma Q=0$. This reason is surely erroneous, for in the above there are no Q's to consider, and the reason fails.

We may therefore reject one of equations (128), say the last, leaving p equations, $(p=q-1)$; thus

$$\left.\begin{aligned} C_1-K_{1q}P_q&=K_{11}P_1+K_{12}P_2+\ldots+K_{1p}P_p\\ C_2-K_{2q}P_q&=K_{21}P_1+K_{22}P_2+\ldots+K_{2p}P_p\\ &\ldots\ldots\ldots\ldots\ldots\ldots\\ C_p-K_{pq}P_q&=K_{p1}P_1+K_{p2}P_2+\ldots+K_{pp}P_p \end{aligned}\right\} \quad . \quad . \quad (131),$$

which give the p potentials in terms of the C's and the rejected P, viz., P_q. This last we may put $=0$; as, if it is not to vanish, the effect is merely to add a common potential all round.

The determinant of K's in this last system of equations is the same as the before mentioned Z, except as regards sign, being negative when p is even and positive when p is odd. Its full expression may be written down mechanically. It may be called the characteristic function of the linear system. It contains in itself the expressions for the resistance external to every branch in the system, which expression can be got by inspection. Let there be only one impressed force E_{12}, and find Γ_{12} the current in the same conductor. If G_{rs} is the coefficient of K_{rs} in Z, we find

$$\Gamma_{12}=K_{12}E_{12}\left\{1+\frac{K_{12}}{Z}(G_{11}+G_{22}-2G_{12})\right\} \quad . \quad (132).$$

Now, Z containing only first powers of the K's, we may write, by picking out the terms containing K_{12}, in the full expression for Z from which the diagonal K's have been eliminated,

$$Z=K_{12}X+Y \quad . \quad . \quad . \quad . \quad . \quad . \quad (133),$$

where X and Y do not contain K_{12}. Further, we may show that

$$-X=G_{11}+G_{22}-2G_{12};$$

which, by (132) gives

$$\Gamma_{12}=K_{12}E_{12}(1-K_{12}X/Z)=K_{12}E_{12}Y/Z, \text{ by (133)},$$
$$=E_{12}(K_{12}^{-1}+X/Y)^{-1}, \text{ by rearrangement}, \quad . \quad (134).$$

Consequently, the resistance external to K_{12} is X/Y. Similarly, by isolating any particular conductivity in the expression for Z, as in (133), we obtain the resistance external to the conductor isolated.

Thus, let there be 4 points joined by 6 conductors (the well known "bridge.") The characteristic function is, if $s_1=a+b+c+d$,

$$Z=(a+b)(c+d)e+(a+c)(b+d)f+s_1ef+ab(c+d)+cd(a+b). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (135).$$

The letters here stand for the conductivities of the branches as shown in the diagram, it being supposed that the four other branches g, h, i, j, are non-existent.

As arranged in (135), it is suitable for showing the resistance external to either e or f, those symbols being isolated.

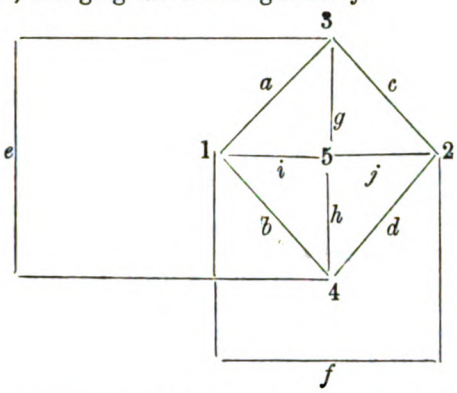
Next, 5 points joined by 10 conductors. In the figure there is an additional junction 5, and four new conductors g, h, i, j connecting it with the former four points. The characteristic function is now the determinant of the K's from K_{11} to K_{44}, and is, the conductivities being expressed by the letters in the

Digitized by Google

diagram expressed thus, using the additional symbol $s_2 = g + h + i + j$,

$$Z = e\{s_2(a+b)(c+d) + s_1 ij + (g+h)[i(c+d) + j(a+b) + ij]\}$$
$$+ f\{s_2(a+c)(b+d) + s_1 gh + (i+j)[g(b+d) + h(a+c) + gh]\}$$
$$+ ef\{s_1 s_2 + (g+h)(i+j)\} + ij\{(a+c)(b+d) + g(b+d) + h(a+c)\}$$
$$+ s_2\{ab(c+d) + cd(a+b)\} + gh\{(a+b)(c+d) + i(c+d) + j(a+b)\}$$
$$+ gi(bc + bd + cd) + gj(ab + ad + bd) + hj(ab + ac + bc)$$
$$+ hi(ac + ad + cd) + ghij \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (136)$$

As before, it is arranged suitably for giving the resistance external to either e or f; the complete coefficient of e, divided by the remaining terms, being the resistance external to e. Similarly for f. To get the resistance external to another conductor, say a, this symbol must be isolated. Or, more easily, rearrange the diagram, changing the lettering suitably.



The characteristic function also gives us the differential equation of the system when the self-induction in some or all the branches is taken into account. Thus, if R_{12} is the resistance from 1 to 2, and L_{12} the coefficient of self-induction, write $R_{12} + L_{12}D$ instead of R_{12} (or $1/K_{12}$) in the characteristic function, and similarly for the others; this being done,

$$Z = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (137)$$

is the differential equation of the system, if D stands for $\frac{d}{dt}$, D^2 for $\frac{d^2}{dt^2}$, &c. And D being algebraic, (137) is the determinantal equation, whose roots give the admissible time constants of subsidence, these being the negative reciprocals of the roots D_1, D_2, &c.

Equation (137) is also the determinantal equation when there are coils with cores in the different branches, but with a different meaning attached to the coefficients K. Let there be a coil with a core in every branch. To distinguish them, it suffices to number the principal symbols before used for a single coil. These are, Γ the coil current, R the resistance of the branch containing the coil, having N windings per unit length l; L the complete coefficient of self-induction of the branch, and M that part of it due to the core; H the magnetic force in the core of length l, and radius c, at distance r from the axis; ρ and μ the specific resistance and permeability of the core; $S = M\rho/2\pi\mu c$. Then

$$P_1 - P_2 = R_{12}\Gamma_{12} + (L_{12} - M_{12})\dot{\Gamma}_{12} + S_{12}\Gamma'_{12} \; . \quad (138)$$

as in (115), is the equation of E.M.F., which takes the place of (125), whilst (124) remains unaltered.

(TO BE CONTINUED.)

VICTORIA INSTALLATION.

The various platforms, waiting rooms, and public and private offices belonging to the London, Chatham, and Dover Railway at Victoria Station require at present about 750 amperes of current at a potential of 116 volts at the bars of the collecting switch-board in the dynamo room. This current is generated by a pair of dynamos manufactured for the purpose by Messrs. Crompton and Co. It was originally intended that these dynamos should be of the Crompton-Bürgin pattern, but after the armatures, as originally designed, were actually made and tried in position, it was found that the Bürgin form of armature was unsuited for such heavy outputs of current, and armatures of the new form designed by Mr. Crompton were substituted with the happiest results, as will be seen hereafter. The field magnets of these two machines are the original ones, and are of cast iron. The length of the space for winding on each arm is 1ft. 9in. by 1ft. 10in. wide. The cross section is elliptical in form, 6 3-16in. being the thickness at the thickest place. The length of the tunnel in the pole pieces in which the armature revolves is 36in., and is cored out to a diameter of 14½in. The winding is in shunt to the armature. The resistance when warm is about 6·5 ohms. The armatures are 36in. long by 14¼in. diameter over all, and are made as follows:—

The steel spindle is grooved or slotted out longitudinally to carry eight radial bars or longitudinal spokes.

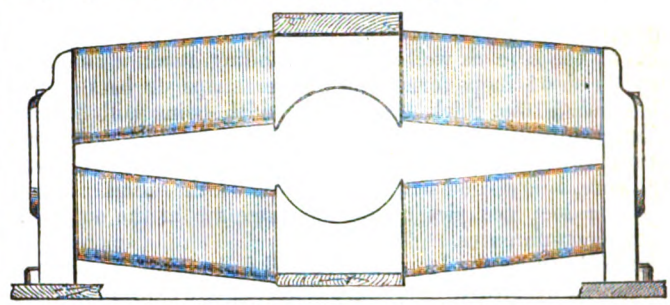


FIG. 1.—Field Magnets at the Victoria Installation.

The outer edges of these spokes are shaped into dovetails, and the iron core, which is exceedingly massive in its proportions, is carried by these radial bars somewhat as follows:—

The core consists of a large number of thin rings or washers of best annealed Swedish charcoal iron, insulated from one another by discs of asbestos paper. They have eight dovetail notches stamped on their inner edges to correspond with the dovetail projections on the radial bars above mentioned.

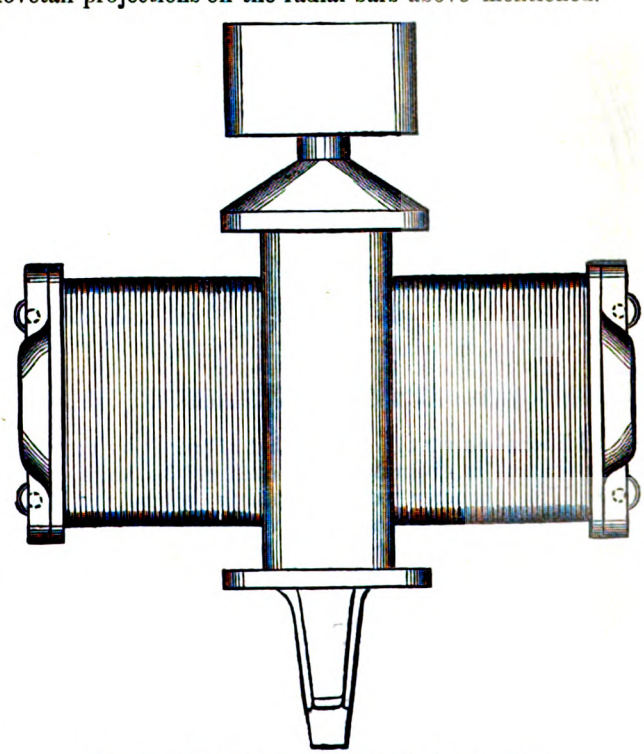

FIG. 2.—Field Magnets at the Victoria Installation.

These discs are slipped on to the radial bars, the notches sliding along the dovetail shaped edges until the full length is made up; they are then secured by the ends of the radial bars being riveted over on to end discs, which are somewhat thicker than the other discs.

At regular intervals spacing strips are inserted, giving spaces for ventilation. The strips are so formed that each ventilating space acts as a fan to pump air from the interior of the ring and throw it outwards, the spacing strips being curved as fan blades of the most approved form for the purpose. The radial bars are of the toughest phosphor bronze, the tensile strength of which is about 40 tons to the square inch, so that

Digitized by Google

the combined spindle, radial bars, and ring core constitute a complete cylinder of enormous strength, both to resist the strains due to tangential inertia, or what is commonly called centrifugal force, and further to resist the enormous torque or driving strain which has to be transmitted to the core from the belt. To further this end the fitting of the radial bars both to the grooves in the steel spindle and to the notches in the discs has been carried out with extreme care, all surfaces being shaped together.

The insulation of the core is carried out in a peculiar manner, so that although the copper bars forming the winding are kept thoroughly insulated from the core itself, yet the insulation itself in no way interferes with the passage of the ventilating current of air, which has free access to every part of the surfaces of the core as well as of the winding itself. The latter consists of 64 loops formed of copper strips or bars, 9-16in wide and 3-16in. thick, the greater width being laid flatways or longitudinally on the outer periphery of the arc; but the return side, which passes through the central space of the ring core, is arranged with its greatest width radial. In this way the loop occupies about the same arc at the outer and inner circumferences.

In both places the loops are spaced fully 3-16in. apart, and are spaced by insulating tubes formed of hard vulcanised fibre. Otherwise these loops are left bare of insulation, but are painted black to promote radiation of heat. The resistance of the armature is ·0096 ohm. The resistance, therefore, of the field magnets is 670 times that of the armature.

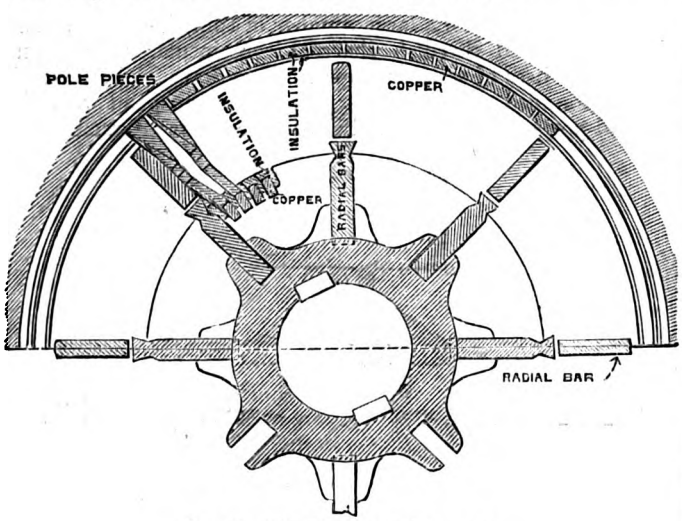

FIG. 3.—The Crompton Armature.

An additional current of air to that afforded by the ventilating space fans is given by the spokes of the large driving pulleys, 17in. diameter, being shaped as helical fan blades. This forces a strong current endways through the armature, and allows of a very large current being passed per square inch of section of the copper winding strips.

The commutators call for no particular description. There are three pairs of brushes, each of which can be rewound or exchanged during the time the full current is passing.

The maximum output of each machine is about 500 amperes at 116 volts, the speed being 900 revolutions per minute; and at this large output—which is equal to 58,000 watts, or 950 60-watt Swan lamps—there is absolutely no sign of sparking at the brushes. The commutators have acquired a beautiful dark surface polish, and the wear of brushes appears to be almost entirely prevented.

The electromotive force of each machine can be varied within considerable limits by the interposition of a rheostat of iron wire in the circuit of its exciting current. Slate boxes containing the rheostats are arrayed against the wall of the dynamo room.

The currents are conveyed from the brushes of the two machines to a pair of large switch-boards of very simple construction.

They consist of four bars of copper of double dovetail or dicebox section. These bars measure 1in. × 1¼in., and are surfaced up bright. The part that enters the backing is held firmly in position by being wedged in with beechwood wedges, cut endways of the grain and soaked in paraffin.

The framework of these switch-boards is cast iron, but the copper bars are perfectly insulated from the cast iron by the beechwood wedges, which form a continuous lining to the grooves in the cast iron. The leads coming from the dynamos are jointed into socket heads, grooved out so that they can be slipped on to the dovetailed section of bar, and there be held in position by copper wedges. The sockets and wedges are surfaced so as to fit the bars very accurately, and in practice it is found that these joints keep perfectly cold even when the largest currents are passing through them for eight or nine hours at a time.

A portion of one lead from each machine is shunted round a Crompton and Kapp current indicator. Each of these two indicators were calibrated in position after the permanent connections had been made, and there is every reason to believe that they still continue to give extremely accurate readings. The accurate and constant measurement of such large currents has been hitherto a great source of difficulty, but in this case the current given by each dynamo can be read off at a glance by any one entering the dynamo room, and the least inequality due to shifting of belts or other cause can be at once detected and remedied.

The dynamos are placed on the floor of the room, and are kept in place by oak chocks, bolted to floor, so arranged that they can be forced back for the purpose of tightening the driving belts by a screw-jack placed in front of each machine. The driving belts are double, and are 10in. wide. The current is led away from the bars on the switch-board by two pairs of cables, each consisting of 19 strands of copper wire, ·200in. in diameter. The total loss in these cables when all lights are on (one pair only being in use at present) is about 4 volts, and the electromotive force at the distant switch-board in the railway station is kept constant within one volt on either side of the standard of 112 volts by the Willan electrical governors, which control the speed of the main engines, and which we propose to describe when we come to the engines themselves.

LAUNCH OF THE "MAGNETA."

An interesting launch was made on Saturday, the 20th December, of a new cable steamer, named the "Magneta," from the building yard of Messrs. Robert Napier and Sons, Govan, Glasgow, the property of the Eastern Extension, Australasia, and China Telegraph Company (Limited), of 66, Old Broad-street, London.

This vessel is entirely built of steel, under special survey at Lloyd's, 100 A1, the boilers and machinery being certified by the Board of Trade.

We shall publish with our first issue in January plans of this fine vessel, with a full description of her cable tanks, cable machinery, and other recent improvements.

The speed of this vessel is estimated at thirteen knots, on a very small consumption of fuel, her engines being of the most improved style.

The vessel is sub-divided into cellular watertight compartments under cable tanks, engines, and round tunnel, all independently connected by a complete system for pumping up and pumping out these tanks while at work laying cable.

The cable tanks are likewise connected to the engine room donkey pumps and with steam-driven Downton pumps for discharging water in tanks overboard, and for other purposes. The vessel has condensing appliances for distilling 5,000 gallons of water daily, which, should the vessel be required at any time for trooping purposes, would be a desirable feature.

The cable tanks are four in number, being built on the top of the water ballast tanks.

The vessel has three watertight compartments forward, besides the ordinary bulkheads, so that in the event of one compartment being punctured the vessel would still be safe.

The engines are 100 horse-power, compound boilers, being built wholly of steel by the same eminent firm.

Digitized by Google

The windlass, steam winches, steering gear, and sounding gear are of the newest design, by first-class manufacturers.

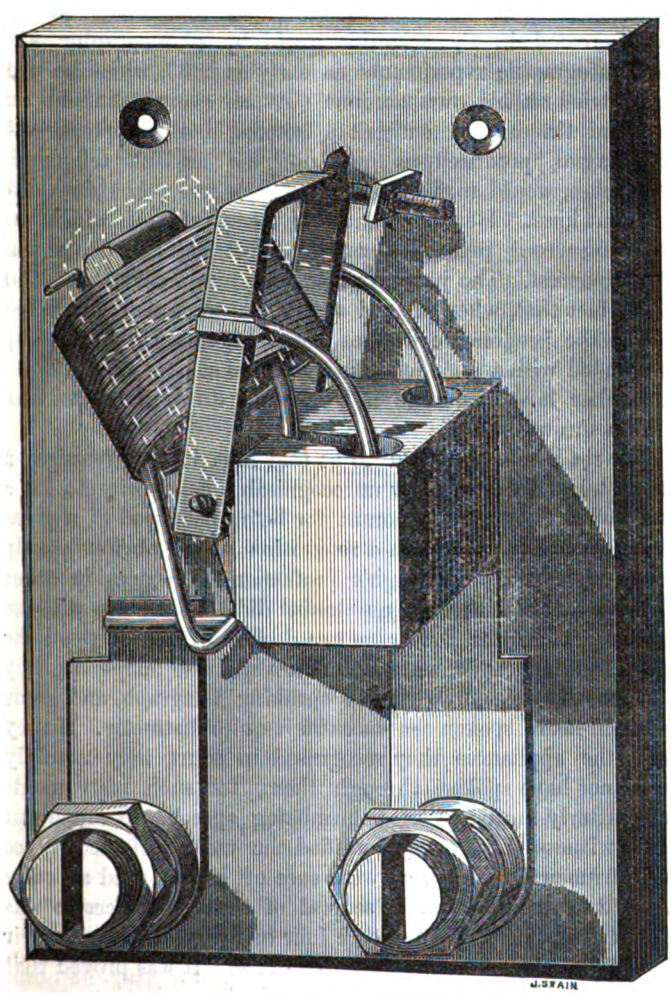
The cable machinery consists of a compound duplex machine with rolled steel frames, with steel cranks, helical wheels, so arranged that picking-up and paying-out can be going on at the same time. This gear is manufactured by Messrs. Johnson and Phillips, of Victoria Works, Charlton, Kent.

The vessel is lit up with upwards of one hundred 20 candle-power incandescent lamps, dynamo engines, and four dynamos and search lamps by the same firm. The "Magneta" will make her trial trip about the 1st of February next, and will afterwards proceed to the Thames to take in cable for Singapore, her destined headquarters.

The vessel is built to the design of Joseph Birnie, of 3, Fenchurch-avenue, London, and we trust will form a creditable addition to the company's fleet. We purpose publishing also the plans of another cable steamer, of somewhat different construction, now almost ready for launching, built by the same firm for the Eastern Telegraph Company, Limited.

THE CUNYNGHAME—WOODHOUSE AND RAWSON AUTOMATIC CUT-OUTS.

A few years ago, when incandescent lamps first came into use, several accidents occurred from the overheating of the



The Cunynghame-Woodhouse and Rawson Cut-Out.

insulated wires when more current passed through them than they were designed to carry. The use of small pieces of lead wire, or fusible cut-outs, which the Edison Company still use, was introduced to obviate this defect. These were afterwards improved upon by several makers, notably Mr. Killingworth Hedges and Messrs. Woodhouse and Rawson. The former in the place of lead used an alloy, rolled out into very thin strips and cut into shape. These strips are protected from mechanical injury by the use of thin pieces of mica. The ends of the strips of alloy pass under pieces of brass screwed down tightly upon them. When more current passes through them than they are designed to carry they are melted, and the circuit broken. Messrs. Woodhouse and Rawson's fusible cut-outs were of the same nature, except that the alloy was fastened on vulcanised fibre and then stamped out to the shape required. The face with the foil was placed downwards, thus guarding it from mechanical injury. Contact was made by two screws, screwing on to the vulcanised fibre pressing the alloy on to pieces of brass. Besides this objection—loss of power and change of melting point through heating—fusible cut-outs are objectionable, because it is impossible to test each plug, and often a considerable variation is found.

Mr. Cunynghame, the author of the well-known book on Electric Lighting, and Messrs. Woodhouse and Rawson have lately brought out an automatic cut-out, which is used in all cases where it is required to sever or make an electric connection when the current or E.M.F. exceeds or falls below a given strength. Its action depends upon the raising of an armature against the action of gravity when the current passing round a small magnet exceeds what the instrument is intended to convey. When the armature is attracted it pulls two copper legs out of two mercury cups, thus severing the connection. The moment before the connection is severed the armature falls over by its own weight to the other side of the electro-magnet, and completely breaks the circuit. Two legs can be put on to the other side to fall into mercury cups and put in a resistance, ring a bell, or do any other work required. A small screw enables the instrument to be set for any current which the size of the wire on the electro-magnet allows. A touch of the finger, or a mechanical arrangement to act after a few moments restores the connection when it is broken. In fixing the instruments, the only precaution needful is to level them; they will then remain in perfect order for years. Little or no electric energy is consumed or lost by the apparatus, as happens with the fusible cut-outs, which, when the current passing through them is near the breaking point, get extremely hot and offer an increased resistance, thus wasting energy. The advantages of an efficient automatic cut-out in connection with shiplighting are particularly apparent. The form described above is not quite suitable, as the motion of the ship has to be considered. A special form in which a spring action is used in place of gravity is made for such purposes.

THE COMMITTEE ON THE ELECTRIC LIGHTING ACT.

The first meeting of the General Committee formed at the instance of Lord Thurlow, chairman of the Anglo-American Brush Electric Light Corporation, was held on Wednesday at the offices of that company. Among those present were Sir Charles Bright, vice-president of the Society of Telegraph Engineers and Electricians; Sir David Salomons, Bart.; Professors Silvanus Thompson, George Forbes, and W. E. Ayrton; Colonel Steuart, Major Flood-Page, Captain Douglas Galton, C.B.; Messrs. J. S. Sellon, R. Hammond, J. W. Swan, R. Campbell, H. Cunynghame, J. I. Courtenay, A. H. Renshaw, F. Ince, and Frank Wynne. Letters of apology for absence were read from Lord Thurlow, Sir Frederick Bramwell, Professor Jamieson, Professor Fleeming Jenkin, and others.

In the unavoidable absence of Lord Thurlow, Mr. J. S. Sellon was voted to the chair; and on the motion of the Chairman, seconded by Mr. Hammond, Mr. E. Garcke was unanimously elected hon. secretary to the committee.

The following names were added to the General Committee:—Shelford Bidwell, E. W. W. Edwards, Clement Higgins, and Musgrave Heaphy. It was then proposed and carried that an executive committee be appointed to prepare draft clauses to be submitted to the Board of Trade, and the following gentlemen were elected by ballot to constitute the executive committee:—Sir Frederick Bramwell, Mr. J. S. Sellon, Mr. R. E. Crompton, Captain Douglas Galton, C.B., Major Flood-Page, Mr. R. Campbell, Mr. R. Hammond, Mr. J. Irving Courtenay, and Mr. J. Staats Forbes, with Lord Thurlow as chairman and Mr. E. Garcke as honorary secretary, to whom any communication may be addressed at 112, Belvedere-road, Lambeth, S.E.

THE DRAWBAUGH TELEPHONE CASE.

The decision in the action "Bell *versus* Drawbaugh" has just been delivered, and by the courtesy of our American contemporary the *Electrical World* we are able to put our readers in early possession of the leading points in this remarkable case. We hope shortly to find space in our columns for a full report of the judge's deliverance. The interests which were at stake are said to be not less than one hundred million dollars, involving as they did the proprietorship of the Bell Telephone system, whose vast dimensions may now be said to be conterminous with the whole civilised world. The originality of Bell's invention remained unchallenged until its pecuniary value proved too great a prize to be let pass without challenge. After some insignificant skirmishes, which were easily swept aside by Bell's invincible forces, a formidable assault was at length planned under the flag of Mr. Drawbaugh, with plenty of material in the shape of hard cash and loose swearing to back him, but with the result, after a stubborn contest, that he and his confederates are driven ignominously from the field.

The story of the Drawbaugh telephone deserves to rank foremost in the history of modern imposture. Whether it was conceived in fraud or in conceit may always remain a moot point; and at what stage conscious deception took up the cue which unconscious self-delusion had manufactured it is difficult to say. To all appearance this stage was reached at the moment when capitalists envious of the fortunes of Bell's invention were looking out for a pliable tool to enable them to deprive it of its legal status or frighten its owners into paying black mail. Be that as it may, however, Mr. Drawbaugh was found. This gentleman is a professional inventor, or, perhaps, we should say rather, he professes to invent. Between the years 1865, or thereabouts, till 1874 he appears to have lived, at least partly, by inventions, which, although they generally failed, and were often mere copies, helped to keep him in easy, if precarious, circumstances. But he made nothing by telephony until 1878. In that year he wrote a memoir of himself, anonymously of course, in one of the local county guides, curiously illustrative of the American saying, recently quoted by Mr. Preece, that Modesty is a great virtue, but you can do a vast deal better without it. Here Drawbaugh is described as the inventor of many things, and as occupying "a proud position at the head of prominent men in Cumberland county." Incidentally he mentions that several kinds of telephones had "engaged his attention." But this was two years after Bell's discovery. In 1874-6 Drawbaugh's business card had been hardly less candid as to his merits; but it says nothing about his telephonic achievements. In 1878 he was interviewed by *The Baltimore American*, but made no claim even then to having forestalled Bell's invention. It must have been after 1878, therefore, that he became aware that he had discovered the electrical talking machine ten years before.

Now, it is on record that he had a string telephone in his brother's shop at that remote date, and that some stir had been created in the scientific world by phonographic and phonautographic experiments as early as 1863, which he probably tried on his own account. At all events the old tea cup and tin canister without a bottom, both supplied with diaphragms, produced as proof of his ancient telephonic researches, would answer quite as well for researches of a quite different kind. He had invented an electrical clock which was made on wrong principles, and his electrical knowledge was of the poorest. The judge, in fact, calls him a charlatan; and it is a fact that, when pressed at the trial to explain what led him to the progressive devices which began with the tea cup and ended with a telephone, he was quite at a loss. "I don't remember how I came to it." Neither do we, but we can form a shrewd guess.

Our readers hardly need to be told that it only requires a string telephone and a few unrecognisable accessories to get a reputation among the ignorant for being possessed of a great electrical discovery. Such a reputation would obviously help to improve Mr. Drawbaugh's professional ventures in other directions; and this he no doubt did. Otherwise we can hardly account for 200 witnesses declaring that between the years 1865 and 1876, when Bell discovered the telephone, they had actually seen Drawbaugh's speaking telegraph, and some of them heard spoken sentences on it quite distinctly. If they used the appliances they recognised in court they certainly could not have spoken through them, for such instruments were utterly incapable of transmitting speech. Numbers of other witnesses, however, identified the more perfected types of instruments, which they were sure of having used as early as 1872 or earlier. But in several of these instances it was shown that the witnesses were four or five years out of their reckoning, which makes all the difference. It was proved that Drawbaugh borrowed a genuine telephone instrument at Harrisburgh as soon as it came into use in his part of the country, and studied it at home for several days. This or a copy of it no doubt astonished the natives, and left far deeper impressions on their memories than the exact dates of their visits to the inventor's emporium.

The testimony of these witnesses is, however, vitiated by the inventor himself, who in fact acted as if he knew nothing of the discovery they confidently give him credit for. He was

Digitized by Google

frequently taking out patents, but he never took a patent for this; he was in communication with patent agents, he had constant negotiations with promoters, he could command capital for his other inventions, but he never solicited anybody for his "talking telegraph," the perfecting of which "was to have made his fortune." So he is reported to have said; but this was to the ignorant and non-electrical community. To the really well informed persons with whom he had many dealings during the period in dispute he was absolutely silent about it. He professes to have been too poor to secure his invention by patent. But this was proved to be false; and he was certainly not too poor to secure a lot of worthless inventions, and he did not hesitate to seek help when he had anything worth spending money upon. He claims to have had in 1872 a telephone more perfect in its details than Bell's first instrument, patented four years later, yet he showed it only to the ignorant, spent not a penny in protecting it, and forgot to say anything about it to the only people who could appreciate its value. What other inference can be drawn from all this than that, although he may have possessed some experimental toys which had amused himself and secured the wonder of his ignorant patrons, he had really contrived nothing in the telephonic line of experiment that was worth patenting? The Court did not believe Drawbaugh's evidence to the contrary, and neither do we.

The proprietors of the Bell Telephone are to be congratulated on having escaped a grave peril. The gravity of the case against them cannot be fully estimated from the foregoing brief outline. There were fully two hundred witnesses to be combated besides the audacious testimony of the claimant himself. That the rightful owners have completely upset the conspiracy once and for all is now almost certain; and the world of invention owes them a debt of gratitude for contesting inch by inch and finally defeating one of the most elaborate and cunningly devised attempts at piracy yet on record. It is much to be regretted that the instigators and abettors in this nefarious business cannot be unearthed and brought to justice.

CORRESPONDENCE.

PAYING FOR SPECIFICATIONS.

[We understand that Messrs. Mackenzie and Brougham's objection in "Engineer's" letter, as published in *The Electrician* of Dec. 6th, is to the first paragraph. We, on behalf of the writer of the letter, unconditionally withdraw the first paragraph of that letter.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been much interested in the correspondence on the above subject, and quite agree with you, sir, that the action of Sir Coutts Lindsay has resulted in the refusal of "almost every company and firm of repute" to tender for the electric lighting of the Grosvenor Gallery.

Why should Sir Coutts Lindsay or anyone else question the *bonâ fide* intentions of those who submit estimates? Mr. Crompton very pertinently puts it in his letter of the 11th inst. that the expenses of those engaged in electric light engineering are very considerable; but does Sir Coutts Lindsay imagine that we send in tenders for amusement?

My experience of installations carried out in the manner it is proposed to light the Grosvenor Gallery is a very unsatisfactory one. One contractor supplies the engines and boilers, another the dynamos, another does the wiring, another supplies the lamps, &c., and if anything goes wrong, as it generally does in such cases, one contractor throws the blame on to another, and it becomes difficult to ascertain who is really at fault. I maintain that the complete installation for lighting the Grosvenor Gallery ought to be carried out by one electric light engineer or electric light firm, as unless this be done I cannot see how it is possible to guarantee the installation satisfactory.

The letter of Messrs. Lewis and Lewis, published in your last issue, is to my mind amusing, as I fail to see anything libellous in the letter of "Engineer." It may be that the letter was, as Mr. Crompton says, "unnecessarily harsh;" but I am one of those people who believe in "hitting the nail" with a good hard blow, and "driving it home."

Should an action for libel be commenced against you I am sure you will be well supported by a large number of those interested in the subject, and shall myself be happy to contribute my "mite" for the defence of such action.

I may just add that I am not one of the unfortunate individuals who have recently lost £3.—Yours, &c.,

Bowdon, Dec. 16, 1884. CHARLES LEVER.

[It will be seen that the paragraph containing the objectionable expression has been withdrawn, leaving the argument before us unchanged. We have not withdrawn it from fear, but simply that we have no desire to hurt anyone's feelings, even by proxy. We are sure that "Engineer" intended merely to "hit hard, hit straight, and hit fair," to which favour he is justly entitled.]

A LAWYER'S SUGGESTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is more than forty years since I signed the roll of the Queen's Bench, and amongst other victories and many defeats I obtained a unanimous judgment of the House of Lords and the Judges who were summoned reversing the unanimous judgment of the Queen's Bench and a divided judgment of the Exchequer Chamber. I am therefore not altogether destitute of experience. Permit me through your columns to suggest to would-be plaintiffs who are desirous of courting the risks not only of a verdict for the defendant but the still more probable verdict (even in the most sanguine view) of one farthing damages, that in the first place they should remember of what they complain, and in the next place that they should ask their solicitors two questions—first, what amount of damages they will guarantee; secondly, what is the limit they will place on their costs. If they can get an answer to these two questions, which I certainly very much doubt, then I do not fear that the answers will greatly cool their ardour. I don't think it would pay, even as an advertisement. —Yours, &c., J. A. S.

Notting-hill, Dec. 18th.

THE WATT AND HORSE-POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I cannot admit that Angelina's general deduction that velocity is distance, and that work, force, and momentum are the same, is quite fair. Granted that the second is unit time, then unit velocity is unit length, and unit momentum is unit force. Granted the foot is unit length, then unit work is unit force; and both second and foot being unity, then units of force, momentum, and work are the same. Granted, also, a unit, Angelina in a unit universe and the Spencerian hypothesis *might* be true dynamically, but let another unit rush in (not in unit time) and both the hypothesis and Angelina's unity would be destroyed.—Yours, &c.,

EDWIN.

CHEAP ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could you kindly inform me through your valuable paper the best and cheapest form of accumulator to light a small scarf pin lamp, giving about two volts, and also where such accumulators are to be obtained? I have tried several was of lighting the lamp, but have always failed to get any good result.—Yours, &c., F. L. C.

Digitized by Google

MEASURING THE EARTH RESISTANCE OF LIGHTNING CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. W. H. Whitehouse will find all the information he wants about "Fahr. Zero" method, &c., in Munro and Jamieson's "Pocket-Book of Electrical Rules and Tables," Second Edition, at pages 141, 142, and 182 to 184.—Yours, &c., ZERO.

ELECTRO-DEPOSITION OF BRASS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could you, through your valuable paper, give me a receipt for making a solution for electro-brassing, also how to work the same, with amount of battery required? I should not have troubled you, only seeing such valuable information in your paper I thought you might assist me.—Yours, &c.,

27, Church-road, Seaforth, Liverpool. H. HAILEY.

THE ELECTRIC ARC.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to hand you the results of a series of experiments on arc lamps made in October last, which, in connection with the discussion now being carried on in your columns, may interest some of your readers. These results I have not before published, my intention having been to completely revise the whole of them, and to add the results of several others of equal importance. As I have had no opportunity of doing so, it may be perhaps advisable to place before your readers the results obtained pending the revision and completion of the experiments.—Yours, &c., W. B. ESSON.

European Telegraph Works, Dalston,
Dec. 6, 1884.

EXPERIMENTS WITH ARC LAMPS, OCT. 16, 1884.

Top carbon positive 13mm. diam. Hardtmuth's soft core. Bottom carbon negative 11mm. diam. Wallace diamond.

The image of the carbons was projected on a screen, and the length of the arc measured accordingly. The length of the arc is given in the tables in inches.

In the first set of experiments the current was by the introduction of compensating resistances in the circuit kept constant, and the E.M.F. corresponding to each different length of arc was observed.

The results were as follow:—

TABLE I.

Amperes.	Volts.	Length of arc in ins.	Remarks.
20	38	·06	Burning quietly.
20	42	·11	"
20	45	·24	"
20	49	·32	"
20	52·2	·44	"
20	56	·54	Slight flame but quiet.
20	62	·68	More flaming.
20	69	·90	Still more.
20	69	1·00	Flickering and unsteady.
15	39	·12	Burning quietly.
15	47	·25	"
15	50	·32	"
15	54	·44	Slight flame.
15	58	·54	Flickering and unsteady.
15	65	·72	" "
15	66	1·08	" "
15	74	1·40	" "
10	36	·06	Burning quietly.
10	41	·08	"
10	52	·24	"
10	56	·36	Flaming slightly.
10	58	·50	Considerable flame.
5	34	·07	Burning quietly.
5	38·8	·12	"
5	47·0	·20	"
5	52·6	·32	"
5	56·0	·48	"

In the second set of experiments, the difference of potential at the terminals of the lamp was kept constant, and the current corresponding to each different length of arc was observed. This set I consider very unsatisfactory. However, I copy them as they stand:—

TABLE II.

Difference of potential.	Current	Length of arc in ins.	Remarks.
60	24	·88	Quiet.
60	20	·56	Flaming.
60	18	·56	Increased flaming.
60	16	·54	"
60	14	·56	"
60	12	·54	"
60	10·5	·52	"
60	8·5	·46	Went out.
50	27	·70	Slight flickering.
50	21	·32	"
50	18	·24	"
50	15	·22	"
50	12·5	·21	Flaming.
50	10	·21	Increased flaming.
50	6	·18	Went out.
40	27	·57	Burning quietly.
40	24	·16	"
40	19	·14	"
40	17	·12	"
40	14·5	·13	"
40	12·5	·14	Slight flicker.
40	10	·14	More flickering.
40	7	·16	Very unsteady.

A third set of readings was obtained in which the length of the arc was maintained constant, and the corresponding E.M.F. and current read off, giving the following results:—

TABLE III.

Amps.	Volts.	Length of arc in ins.	Remarks.
23·5	66	·96	Flaring.
20·4	68	·96	"
15·0	70·6	·96	"
12·4	74·4	·96	Very unsteady.
10·0	74·0	·96	Went out.
24·0	54	·64	3 inch flame.
21·5	59	·64	"
19·0	62·4	·64	2½ inch flame.
16·0	64	·64	"
10·0	70	·64	Steadier.
8·5	70·4	·64	Unsteady and flared out.
24·6	43·4	·48	Fairly steady.
20·0	52·2	·48	Slight flicker.
18·0	54·0	·48	"
14·5	58·0	·48	Worse.
12·5	61·0	·48	Flaring.
8·5	65·0	·48	Flared out.
25	45	·32	Fairly steady.
23·5	48·4	·32	"
21·2	50·4	·32	Slight flicker.
21·0	51·0	·32	More.
19·4	51·4	·32	More.
14·0	53·0	·32	More.
12·5	54·0	·32	More.
11·0	55·0	·32	Very unsteady.
9·0	57·0	·32	Went out.

Digitized by Google

Amps.	Volts.	Length of arc in ins.	Remarks.
23·6	38·0	·16	Burning quietly.
23·0	10·0	·16	„
23·2	41·2	·16	„
21·0	41·6	·16	„
20·0	42·4	·16	„
19·0	43·4	·16	Slight flicker.
14·5	46·0	·16	Rather more.
11·5	48·0	·16	„
9·5	48·0	·16	„
6·5	52·0	·16	Went out.
23	30	·1	Light steady, but carbons mushrooming.
22	32·4	·1	
21·5	34	·1	Arc too short to measure properly.
20	36	·1	
18·5	38	·1	Flickering.
18	40	·1	„
15	36·4	·1	„
13	36	·1	„
8·5	42	·1	„

It is almost unnecessary to add that the lamp employed for the above experiments was regulated by hand, as no lamp made could fulfil the requirements of the tests. It will be observed that these results bear out the truth of much that Mr. White has said regarding the behaviour of arc lamps.

AN ELECTRIC TRAMWAY.

We had this week an opportunity of witnessing some trials made with a tramcar propelled by electricity on a short experimental line laid down in the yard of the Electric Power Storage Company. About the line we need not say much; it is as rough as can possibly be imagined, and contains within its short length of 400ft. as many nasty bits as if it were put down for the express purpose of making locomotion as difficult as possible. This, indeed, was the object in designing the line, as it was thought necessary to test the system under the most unfavourable condition. In the middle of the length there is a curve of 35ft. radius, the line at the same time rising 1 in 40, so that it is impossible to make a rush for the hill. The gradient of the line increases from 1 in 40 at the curve to 1 in 17 at the end. It is needless to say that so steep a line could not be worked with horse traction, and that the task which Mr. Reckenzaun, the inventor of the system, has set himself is more severe than necessary. The car is propelled by two of Reckenzaun's motors, driven by accumulators placed on trays under the seats. For the convenince of quickly changing the cells the trays run on rollers, and a special trolly is brought up to the car, on to which the exhausted cells are pushed. The same trolly serves to bring the new set of cells up to the car, and all the work of changing cells can be performed by one man in about the same time as would be required to change the horses with an ordinary car.

A most ingenious arrangement of compound switch enables the driver to get a variable power—from four to sixteen horse-power—out of the two motors collectively. The motors, gearing, and accessories weigh only about 10cwt., whilst the accumulators weigh about 1¼ ton. These weights compare most favourably with the weights of a steam or compressed air locomotive of equal power, and the absence of steam, smoke, and noise is also a strong point in favour of electrical traction. During our visit Mr. Reckenzaun started the car without difficulty on an incline of 1 in 30, and the speed obtained on the level can vary from 3 to 10 miles an hour.

As mentioned above there are two motors, each capable of developing from 2 to 8 horse-power. The motors are fixed on bogies, each bogie forming a complete whole ready to be put under any ordinary car. The great advantage of this arrangement is that existing rolling stock can be transformed for electrical traction with great facility, and by subdividing the weight of the motors on two bogies, and by distributing the weight of the accumulators over the whole length of the car there is no undue increase of pressure on any of the wheels, and no alteration in the permanent way is required. The car is lighted by four Swan lamps, and electric bells are fitted for communication between passengers, conductor, and driver. On each end there is the ordinary hand brake, and the driver has control over the motors by two levers—one for reversing, the other for varying the power. One charge will work the loaded car for two hours, stopping, reversing, and starting on an average sixty times an hour. The experimental line at Millwall is hardly sufficient to form a correct estimate of the cost of electrical traction, but from experiments made during the last two months, Mr. Reckenzaun has approximately computed the working cost at 3½d. per car mile. This includes 15 per cent. depreciation on machinery and 50 per cent. on accumulators.

The accumulators are a special type, made by the Electric Power Storage Company, and the whole of the work was carried out by this company to Mr. Reckenzaun's designs.

ON THE ELECTRIC LIGHT.*

BY ALFRED RICHARD SENNETT, A.M.I.C.E.

(CONCLUDED FROM PAGE 94.)

In the ordinary holophotal projectors the crater is turned in the direction in which it is desired to project the light, the divergent rays being rendered parallel by the prismatic zones of the dioptric lens; whilst, in what is known as the Mangin projector, the crater is turned in the opposite direction, and faces a concave mirror, the peculiarity of which consists in the fact that the outer and inner surfaces, namely, the silvered and unsilvered surfaces, have different degrees of concavity, the ratio of the radii being so adjusted that the inner (transparent) surface corrects the spherical aberration of the outer (silvered) one.

For ordinary industrial purposes, it is generally required to illuminate uniformly a horizontal plane at a certain distance below the arc. Reference to the diagrams (Figs. 8 to 12) will show that this is rather imperfectly accomplished by the unaided arc, since the lower or negative electrode casts a circular shadow on the horizontal plane, the area of such shadow increasing with the square of the height of the arc, which should always be great to obtain economy and uniformity in lighting. In order to obviate this difficulty, the author suggests the method of utilising the rays proceeding in upward and horizontal directions, and which are useless for the illumination of ground area, by surrounding the arc in and above its horizontal plane by an annular totally reflecting prism, having angles such that rays originally having an upward and horizontal direction are turned downwards and made to illuminate the otherwise less intensely illuminated portion before mentioned. The reflected rays may be made to take any required direction by curving the totally reflecting side of the prism. In lamps for industrial purposes, in which it is required to attain this end in an inexpensive manner, the annular prisms might be constructed of sheets of glass, filling the interior with a liquid, say distilled water.

In many instances, however, it is of more importance to diffuse the light uniformly in all directions and in such manner as to obviate the production of shadows.

Diffusion of the Light of the Electric Arc.—On account of the very small space occupied by the electric arc, and of its great illuminating power, the resulting shadows are extremely dense and well defined; and it is therefore generally found necessary to employ devices for diffusing the light.

The usual method is to place the arc within a globe of ground, frosted, opal, or alabastine glass. The globes should be of large dimensions; for, as every part of the diffusing medium becomes self-luminous and may be considered to be giving out light in all directions, it is clear that shadows, when an arc is surrounded by a diffusing globe of large dimensions, will be much less clearly defined at their edges, and will be fainter (if the object be small and moderately near the light) than if the light be naked or one provided with but a small globe.

However, the loss of light by absorption in various diffusing media has not been thoroughly investigated, and the results which have been obtained are very discordant. In measuring directly by first taking a reading of the naked light and then interposing the substance whose absorption is required to be ascertained, and afterwards taking another reading, the result is as much an indication of the dispersive and reflective effect of

* Paper read at a Supplementary Meeting of the Institution of Civil Engineers.

Digitized by Google

that particular substance as of the light absorbed, since the intensity of the light which originally fell upon the screen of the photometer is, by the use of the diffusing medium, diminished by being caused to occupy a larger area, and also by many of the waves being turned back by reflection. The loss will therefore vary with—

1st. The distance of the specimen from the screen of the photometer.

2nd. The size of the specimen or that of the aperture through which the light is admitted to it.

3rd. Its reflective effect.

The author proved the accuracy of the first assumption by taking separate sets of readings, one set at a great and others at smaller distances from the light. The second assumption was too obvious to need verification. Figs. 13 and 14 will show this.

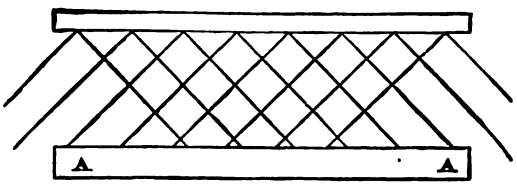

FIG. 13.

Imagine the specimen to be composed of an infinite number of bi-concave lenses, then it is evident that the amount of light falling on the given area A will vary with the first and second conditions.

Another method of diffusing electric light, which is very effective, but which is generally considered to entail great loss of light, is that in which the arc is concealed from view, the resulting light being due entirely to reflection. Doubtless a large amount of light is lost by this method, but it must be remembered that a smaller amount of well-diffused light is often quite as efficacious as a much larger amount wanting in uniformity of distribution. This is especially the case in manufactories in which delicate operations are carried on, or where machinery in motion casts moving shadows. For physiological reasons, also, this is true; for if the eye be not called upon to respond to great variations in intensity of the light, a smaller amount will suffice. If the direct rays from a powerful source of light fall upon the retina, the workman or workwoman will not recover his or her maximum

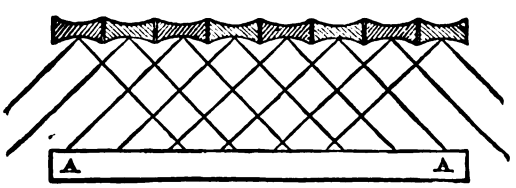

FIG. 14.

sensibility of vision for a perceptible time after. The author has made some rough experiments in this direction, and has found that the period before normal sensibility is regained is longer the more intense the light, and that this period is very considerable. He also found that it varied to a great extent with the colour of the light.

Relative Efficiencies.—The comparison of the efficiencies of the different modes of illumination is an interesting and instructive consideration, but it is one beset with considerable difficulty, as scarcely any complete set of efficiencies has been taken. The greatest difficulty, and probable point of inaccuracy, is in the photometric measurements, as the readings of the instruments used for measuring the candle-power of an illuminant depend greatly upon the difference in colour of the various sources of illumination; again, in no illuminant is the illuminating power the same in every direction. To compare the electric arc and a gas flame, for example, it must be borne in mind that the distribution of light around the source is not uniform, and that the gas flame occupies a perceptible space; obviously, then, some different arrangement is necessary for measuring the power of each light. As a way of effecting a comparison it has been suggested to take a number of readings at different angles, and to consider the average as the candle-power of the light. This meets the difficulty to a certain extent, and is the method upon which the author has based his calculations. The commercial efficiency may, however, be very different. By commercial efficiency is meant the amount of light obtained in the place where it is required. Thus, suppose A and B to give equal lights (average of all directions), and it is wished to have the greatest light at an angle of 45°, then should A give more than its average and B less than its average; A has greater efficiency for this particular place. There may even be a light which has a greater average intensity giving a less degree of illumination in one direction than that emitted from sources of less average intensity.

Other difficulties are the different illuminating powers of various gases, the different efficiencies due to the methods and temperatures at which they are burnt, and the different efficiencies of arcs of various powers.

The following table may be taken as a fair comparison of the efficiencies under these circumstances. The table is not intended to be a comparison of the costs, but only of the efficiency of transformation; the cost efficiency depends not only on the efficiency of transformation but also on the economy of the means of transformation.

TABLE SHOWING CANDLE-POWER PRODUCED PER HOUR BY 1LB. OF COAL TRANSFORMED IN EIGHT DIFFERENT WAYS INTO LIGHT.

Method of Transformation.	Gas produced.	Coal required per H.P. effective per hour.	Candles per 5 c. ft. per hour.	Gas per effective H.P. per hour.	H.P. given to dynamo.	Electrical H.P. at terminals of lamps.	Candle-power per effective H.P. at terminal.	Candle-power per hour obtained.	Rel. amount of light, taking ordinary gas burner as 1.
	c. ft.			c. ft.					
Coal gas	4·4	...	12	...	...	...	...	10·6	1·0
Coal gas, gas engine, dynamo, and arc lamp	4·4	...	...	30	0·15	0·11	1,200	126·6	11·9
Coal gas, gas engine, dynamo and incandescent lamps.....	4·4	...	...	30	0·15	0·11	200	21·1	2·0
Dowson gas, gas engine, dynamo, and arc lamp	83·3	...	...	125	0·67	0·48	1,200	576·0	54·3
Dowson gas, gas engine, dynamo, and incandescence lamps	83·3	...	...	125	0·67	0·48	200	96·0	9·0
Steam engine, dynamo, and arc lamp	...	2½lb to 4lb	...	...	0·40 to 0·25	0·29 to 0·18	1,200	348·0 to 216·0	32·8 to 20·4
Steam engine, dynamo, and incandescence lamps ...	...	2½lb to 4lb	...	...	0·40 to 0·25	0·29 to 0·18	200	58·0 to 36·0	5·5 to 3·4
Siemens burner, ordinary gas	4·4	...	30	...	...	...	...	27·0	2·5

It should be remembered in reviewing the above table, that on account of its showing the light produced by 1lb. of coal the by-products resulting from the production of ordinary coal gas cannot be considered. If it had been a consideration of the cost efficiencies instead of light, the efficiencies of Nos. 1, 2, 3, and 8 would have been much higher, as in this case the value of the by-products might have been taken into account.

Data assumed, efficiency of dynamo... 80 per cent.
,, efficiency of cables ... 90 ,,
,, good steam engine..... 2½lb. of coal per effective horse-power per hour.
,, average ,, ... 4lb. ,, ,,

The Electrodes.—When the arc is produced in air (which is always the case when employed for industrial purposes) the carbon electrodes are gradually consumed in the ratio of about 1 part of the negative to 2 parts of the positive. This consumption is due to the gradual oxidation of the heated points, and to the complete combustion of the moving particles which are projected chiefly from the positive towards the negative.

Now, since the great efficiency of the electric arc consists in its ability of condensing into an exceedingly small space a large amount of heat, it is advisable to employ as electrodes a carbon of very low thermal conductivity in order to localise the heat as much as possible, so as to increase the light and prevent oxidation at a temperature too low to produce light; at the same time the electrical conductivity should be as high as practicable.

Purity, hardness, and homogeneity are the chief desiderata in a good carbon. Out of seven specimens of carbon of well known make the author found the most light to be produced by the one

Digitized by Google

containing the least amount of impurities. The following shows the amount of ash in each :—

	Per cent.
S	12·45
E C C V	5·35
G *y*	3·72
B	3·50
C C C *d*	2·80
C	2·84
G *n* (original Gaudoin)	1·80

The purest carbon, and that giving the highest efficiency, was the last, which was made by M. Gaudoin. The others are at present in the market, and the author abstains from giving the names. The redness of the ashes affords an approximate indication of the amount of iron contained in each specimen. All attempts to increase the illuminating power of the arc, by the introduction of various materials during the manufacture of the carbons, have failed, as the decomposition of such materials produces gases which, at the high temperature of the arc, become conductors. Several methods of preventing the wasting away of the carbons have been patented. One with which the author was connected consisted in surrounding the electrodes with a hydro-carbon vapour, which, at the high temperature of the arc, became decomposed, and a very hard carbon was deposited upon the electrode; but it was found that the heated gas increased the conductivity of the arc, and the loss of light was very great. In order to obviate the employment of mechanism, and the necessity of frequently renewing the carbon rods, the author attempted to substitute for the solid electrodes powdered carbon contained in large vessels connected with metallic tubes, furnished with non-conducting nozzles of very refractory material. A current of great electromotive force, however, was required, and the light was of a violet hue. As a means of obviating the necessity of repeatedly renewing the carbons the author constructed a lamp which made its own electrodes as required. The lamp contained two cylinders provided with plungers which were forced in by a powerful spiral spring, the uncoiling of which gave motion to nut-wheels working on screwed prolongations of the plungers. It was, however, intended to substitute for this in practice a heavy weight descending within the lamp column. The cylinders were filled with powdered carbon mixed with treacle, and one end of each cylinder was provided with a 13-millimetre hole, which acted as the draw-plate employed in the manufacture of carbons. The direction of the carbon rods was controlled by two guide-tubes pivoted at one of their extremities to the covers of the cylinders. These tubes were inclined to each other at an angle, and motion was imparted to them (in order to regulate the length of arc) by means of a solenoid and plunger, the feed being given by the train of wheels driving the plungers, thereby increasing the length of the electrodes. The action of the lamp was satisfactory, but in this, as in the previous instance, the light was blue, owing probably to insufficient density of the electrodes. Coating the electrodes with a thin layer of metal (generally copper, nickel, or iron) increases their durability.

The importance of purity and density in the carbons cannot be too strongly pointed out. No mechanism, however delicate, can be devised to produce a steady light if imperfect carbons be employed.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The annual meeting of this society was held on Thursday, 11th inst., at the Institution of Civil Engineers, Great George-street, Westminster, Professor ADAMS, president, in the chair. In the course of the report for the past year it was announced the premiums for papers read before the society had been awarded as follows:—The Society's premium of £10 to Professor G. FORBES, the Fahie premium of £5 to Dr. W. H. STONE, and the Paris Congress premium of £5 to Mr. H. C. MANCE. Honourable mention also was made of Mr. W. Mordey's paper. Many valuable additions had been made to the library during the year, chiefly by liberal donations of friends of the society through the instrumentality of its indefatigable librarian, Mr. FROST. The report being adopted, votes of thanks were passed by the meeting to the Institution of Civil Engineers for the continued loan of its rooms to the society; to the honorary secretaries of the society abroad; to the honorary treasurer, Mr. E. GRAVES; to the auditors, and to the honorary solicitor, Mr. BRISTOW. Voting papers having been deposited in the ballot-box, it was taken away in charge of two scrutineers, at half-past eight; and Mr. W. H. PREECE, F.R.S., then delivered an interesting address on Electricity in America in 1884. After reference to his former visit to America, in company with Mr. Fischer in 1877, which was a purely official visit, for the purposes of the Post Office, Mr. Preece described his journey to Montreal, in company with members of the British Association, which for the first time in its history, held its meeting this year outside the boundary of the United Kingdom. Their party on board the "Parisian" was nearly 200 strong, and the route selected was by way of the St. Lawrence—a route which brought them within 200 miles of the Greenland shores, and although in the height of summer they experienced most inclement weather during a considerable part of the journey. Altogether it was not an attractive route, except to people who preferred any discomfort rather than that of a rough sea, which, of course, was greatly reduced by taking the St. Lawrence.

Arrived at Montreal, some 1,700 visitors were assembled to make up the gathering, of whom about 600 had crossed the Atlantic. The rest were Canadians and 200 Americans. Apart from the actual business of the meeting there were unlimited entertainments of a social and entertaining kind, and many admirably organised excursions to see the beauties and peculiarities of the country. Nothing could exceed the courtesy and hospitality of their entertainers, and the careful attention to their visitors' comfort throughout. The meeting itself was not, as has sometimes happened, of a specially electrical character, and no striking novelty in that field of science came to light on this occasion. Perhaps an exception should be made in respect to Professor Oliver Lodge's remarkable discourse on the seat of the E.M.F. in the voltaic cell, a discourse so fresh, so brilliant, and so lucid that it gained the admiration of everyone who heard it; and it was to be hoped that this society would have the advantage of hearing it from Professor Lodge's own lips. The conduct of the meeting was under the guidance of Lord Rayleigh, who won golden opinions everywhere as a pattern man of business, an eminent man of science, and an English gentleman. In his own department Sir W. Thomson also sustained the credit of Great Britain in the higher speculations of science.

Leaving Montreal Mr. Preece was induced, much against his will, to visit the American Association, which was holding its meeting at Philadelphia. There the heat was most intense, ranging from 100 all the daytime to 90 all the night, accompanied by American insects of a most ferocious breed. The edification in this city hardly compensated for the discomforts experienced in it, notwithstanding the unfailing hospitality of American hosts. In the course of his travels, which were pretty extensive, Mr. Preece visited Pittsburgh, where he saw the utilisation of natural gas obtained in the vicinity, and went to many other places where educational and scientific establishments have been endowed by private munificence to an extent quite unknown in this country. Wherever he went he of course made a point of inquiring into the working of telegraphy, telephony, and the electric light, the results of which he would state further on. Returning to the subject of the American Association, it was interesting to electricians only, or chiefly, in the discussion which took place on "Hall's Effect," a discussion in which, he was proud to say, our English contingent held their own with much credit to the home country. Amongst the speakers he mentioned particularly Professors Forbes, Silvanus Thompson, and Fitzgerald. The Conference of Electricians was simultaneously held during this visit. It was instituted by the U.S. Government for the purpose of discussing the decisions of the Paris Electrical Congress with reference to electrical units. Those decisions after full discussion were adopted, although the chairman, Professor Rowland, showed their inaccuracy in at least one particular, uniformity of measurement throughout the world being considered of such paramount importance as to outweigh any little departure from scientific exactness. Mr. Preece's own suggestion for substituting a standard of 1,000 watts for the horse-power was also discussed and favourably received. A discussion of some interest likewise arose on Professor Rowland's theory of the dynamo—a theory upon which there was great divergence of opinion. In this relation Mr. Preece mentioned the remarkable fact that whilst alternate current machines were preferred in this country, they were hardly known in the States, great difficulty having been experienced in obtaining one even for lecture purposes. Earth currents, atmospheric electricity, telephony and the disturbances to which it is liable, were also subjects of discussion at this Conference.

While Mr. Preece was in America the country was suffering from an acute attack of that mania from which Europe is hardly yet recovering—namely, the exhibition craze. There were exhibitions everywhere, most of them claiming to be the largest the world had ever seen. He visited many of these, and travelled over a good bit of country. He was thus enabled to form an opinion of the progress made in electrical discovery and enterprise since 1877. The extension of the telegraphic system had been very great. The wires under the control of the Western Union Company measured 433,726 miles, against 200,000 miles seven years ago, an increase, however, largely due to the wholesale amalgamations which that Company had accomplished by absorbing other large companies. But of scientific progress he could only describe it as *nil*. On his former visit he brought back many useful wrinkles; now we could, he thought, teach the Americans a good deal, which, however, they seemed disinclined to learn, displaying a marked jealousy of English inventions. An exception in this respect

Digitized by Google

was the adoption of the Wheatstone fast-speed instrument, which had got a firm footing on American soil, and was largely used on the Western Union lines. An exception of the opposite kind—the only one deserving of special notice—was Delany's multiplex sytem, an adaptation of the French invention described to the society by Captain Webber after the Paris Electrical Exhibition. Delany has applied the ingenious principle of that discovery to Morse working, with the result that six messages could be keyed in the ordinary manner in the same direction at one time. It is to be brought here next year, and Mr. Preece could promise it a fair trial on the Government lines of this country.

As regards telephonic progress in America, we in England could hardly form any conception of the extent to which its use had spread on the other side of the Atlantic. People here complained of the restrictions on telephonic enterprise through Post Office interference [hear, hear]; but compared with the conditions they had to submit to in the States, the telephone companies in these islands were exceedingly well off [laughter]. The American local authorities took every occasion possible to tax the companies, and sometimes their impositions amounted to more than fifty per cent. of the gross earnings; whereas the demand of the Post Office here was only a modest ten per cent. The charges, too, were higher than in England. In Chicago it is £26 per annum; in Philadelphia £25; whilst in New York the "Law" system charged £44, and ordinary systems exacted £35.

Their instruments are no better, but rather worse than ours, although the exchanges are decidedly superior. As to the lines, they are as bad as they well can be in many instances. Notwithstanding the high charges and imperfect appliances, however, there are 986 exchanges, nearly 90,000 miles of telephone wire, and 517,749 telephones in use; and in New York and neighbourhood alone there are 10,600 subscribers—nearly as many as the subscribers in all England put together. The fact was, the conditions of climate, habit, social life, and commercial intercourse in the States favoured this means of communication. Messengers are expensive and almost unobtainable, and whilst we are glad of an excuse for getting outside our offices the Americans gladly lay hold of every appliance for saving physical exertion and the trouble of moving. One consequence of this extraordinary telephonic development is a villainous array of poles along the main thoroughfares, to the complete disfigurement of any architectural merits they may pretend to. In the Broadway, New York, there are six distinct lines of poles; and a more hideous set of erections cannot be found anywhere. Besides this, they are not free from danger; and while he was there he heard of at least seven cases of fire directly traceable to the falling of high tension current wires.

In conclusion, Mr. Preece remarked that as he had so recently spoken at the Society of Arts on Electric Lighting in America, there was no need to repeat his observations here. He, however, referred to Edison's achievements in this line of business, stating that as far as New York was concerned, that bold and ingenious inventor had entirely solved the problem of electric lighting. Finally, he could not help contrasting his own views of the Americans and American life with those of Mr. Capper, published in the *Pall Mall Gazette* on the previous Tuesday. For himself he had nothing but good to say of them; and at all events, he was sure that members of the electrical profession would ever find sympathy and a hearty welcome in the United States, not less than among our fellow subjects in the Canadian Dominion.

In the course of Mr. Preece's address the scrutineers returned with their report upon the balloting. With due solemnity the President communicated the result to the meeting, reading out a list of names which tallied exactly with the printed ballot list supplied by the Council,—a coincidence which evoked the exemplary applause of members who had gone through the formality of putting their papers into the box.

LEGAL.

The Gulcher Electric Light and Power Company (Limited).

On Saturday, the 13th inst., before Mr. Justice Chitty, two petitions were presented for winding up this company, one by Mr. Norton, a late director of the company, who claimed to be a creditor for fees due to him as director, and the other by Mr. Henry Crookes, the company's electrical engineer, who claimed to be a creditor for an arrear of salary, and by two shareholders. The company was formed in May, 1882, with a capital of £300.000, subsequently reduced to £150,000, in shares of £5 each. The company not having met with the success anticipated, a general meeting of the shareholders was held on the 4th inst. for the purpose of considering a report of the directors, in which they suggested a voluntary winding up, stating that they did not feel justified in continuing to carry on the company without the assent of the shareholders. A resolution was then passed adopting the report and accounts, but with some dissentients. The secretary of the company in an affidavit in opposition to the petitions stated that the company was perfectly solvent, and that it was their intention to take proceedings against their late directors for alleged negligence and misfeasance, but the debts claimed by Messrs. Norton and Crookes were not actually disputed.

After a long discussion, his Lordship dismissed Norton's petition on certain terms, by which the petitioner's debt was to be secured to him on condition of his paying the calls due from him on his shares, and the company undertaking to commence an action against the directors to substantiate the charges made in the secretary's affidavit.

As to Crookes' petition, Mr. M'Naghten (who appeared for the company) offered to pay Mr. Crookes' debt, with costs, upon which terms

His Lordship accordingly dismissed that petition.

The following letters have appeared on this subject in *The Times*:—

"Sir: The Gülcher Electric Light and Power Company (Limited) has this day concluded a contract for lighting the Alexandra Palace with the electric light.

"This contract would have been signed a fortnight ago but for the two petitions to wind up the company which have been hanging over this company for the last month, and were only dismissed on Saturday.

"The case affords a striking instance of the extent to which a joint stock company's business may be paralysed by petitions of the kind. The tender for the above contract was accepted by the Palace Company on the 1st of December instant subject to our getting the petitions dismissed on the following Saturday.

"On Saturday, the 6th inst., they were allowed by the Judge to stand over for a week.

"By dint of great pressure the Palace Company were induced to keep the contract open for another week, but they distinctly warned us that under no circumstances could they keep it open beyond to-day.

"On Saturday last the first petition (Mr. Norton's) came on and lasted until the rising of the Court, when it was dismissed upon terms. As an action is now pending by the company against Mr. Norton and others affecting the fees claimed by him it would be improper to criticise this petition.

"With regard to the other (Mr. Crookes's) it was about to stand over for another week, and the alternative presented to this company was either to pay this disputed claim or to throw up the Alexandra Palace contract. Under the above circumstances, and only under the above circumstances, the company elected to pay Mr. Crookes and his solicitors' costs and get this petition also dismissed.

"With regard to your reporter's account of what took place, he has accurately stated the case of the petitioner Norton as presented by that petitioner's counsel, but he has omitted to state what also came out in evidence, viz., that so far from being insolvent, as alleged, this company has no debts; that an overwhelming majority of the shareholders opposed any winding up whatever; and that the debenture holders and alleged creditors who supported the petitions consisted, as to debenture holders, of Mr. Crookes and his family and their solicitors; and as to creditors, of the petitioner Norton's co-directors and the former solicitors of the company.

"The claims of the late Directors and solicitors have always been resisted by the present Board, and an action is now being brought against them by the company.

"I trust that in justice to this company you will insert this explanation of a report which, unexplained, is calculated to do this company serious injury.

"I am, Sir, your obedient servant,

"D. De Castro, Chairman of the Gülcher Electric Light and Power Company (Limited).

"4, Coleman-street, E.C., Dec. 15."

"Sir: We have seen the letter of Mr. De Castro, the chairman of the Gülcher Electric Light and Power Company (Limited), which appears in *The Times* of to-day.

"It is impossible in a letter to explain all the reasons which actuated our clients in presenting the petition for winding up the company, but, in justice to them, we may state that they would not have followed this course except for the report and accounts of the directors, which were forwarded to the shareholders on the 19th November last. The balance-sheet, in the opinion of our clients, showed a very disastrous state of things, and the cash at the bank appeared to consist of the sum of £17 7s. 5d. only.

"The report of the directors, moreover, stated that it was with the greatest regret they had come to the conclusion to which they had been compelled to come, and the report then proceeds as follows:—

"'That conclusion is—To submit to the shareholders at the approaching general meeting whether, in view of the circumstances above stated, the company should be voluntarily wound up, or whether its business as a manufacturing company should be modified or suspended for a time until the company has recovered from the various persons against whom it has claims sufficient money to justify it in resuming more active operations and in taking advantage of the reaction in favour of electric lighting which seems to be setting in.'

"The whole report and accounts, but specially the extract above-mentioned, as also the fact that the whole of the Board tendered its resignation, and placed the affairs of the company once more in the hands of the shareholders, were among the reasons which induced our clients to take the course they did, as they considered it undesirable that under the circumstances the liquidation of the company should be in the hands of the present Board or those nominated by them.

"We are, Sir, your obedient servants,

"Solicitors for the Petitioners.

"40 and 42, Queen Victoria-street, E.C., Dec. 16."

COMPANIES' MEETINGS & REPORTS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

The third ordinary general meeting of the shareholders of this Company, originally held on the 23rd of May, 1884, and by adjournment on the 25th of July, 1884, on which last-mentioned date the said meeting was further adjourned, was, pursuant to the last-mentioned adjournment, held on Tuesday last at the City Terminus Hotel, Cannon-street, E.C., for the purpose of continuing and completing the business of the said ordinary general meeting. Mr. C. L. W. Fitz-Gerald presided.

The SECRETARY (Mr. Charles Curtoys) read the notice calling the meeting. The further report of the committee of investigation was taken as read.

The CHAIRMAN: Gentlemen, time is money, so I do not mean to detain you long. I think I must make a few remarks first of all on the allotment of shares. It appears to the committee that that allotment was a very discreditable transaction to the late Board, and there is one thing that strikes me as very remarkable, and that is that there should have been what I must term a double allotment—one on the 22nd of April and a second on the 26th; because there must have been a reason for that, although I do not know what the reason was. You find stated in the report here that Sir Julius Vogel sent in a written application for 1,000 shares, and that he was alloted on that letter 3,330 shares, and in the allotment register this 1,000 shares was altered to 5,000, and there was no further written application made. Now, the counsel's opinion states that Sir Julius Vogel is, in respect of any shares over and above the 1,000 which he applied for, liable to the Company for the profit he made on the sale of those shares. That is very just I think if one considers it, and if you would allow me to suggest it, I am of opinion that the question of taking proceedings against Sir Julius Vogel should be left in the hands of the Board. I think by that means we may possibly find some way of getting back a sum of money for the shareholders from that gentleman. I hope we may. At all events we can but try. Now, before I go any further I should just like to say a word or two on the subject of the circular which the Directors sent round to the shareholders informing them that they thought they would be in a position to pay regularly quarterly dividends at the rate of 10 per cent. per annum. I think that is a very irregular thing to do. I do not recollect a case of the kind ever happening before. It seems to me very irregular. It certainly was likely to lead shareholders to purchase shares in the market; and then we come to the fact that almost immediately after that circular was sent round, Sir Julius Vogel was selling his shares. Well, gentlemen, I hardly know myself what to say of a proceeding of that sort. At any rate that is what absolutely happened, and I think I need say no more on the point beyond this—that we will use every endeavour to get something back from Sir Julius Vogel. Of course we do not for a moment contend that the profit was not earned. Those dividends were earned undoubtedly. There cannot be any question about that. The only question in my mind is whether they ought to have been divided so quickly. I think it would have been more prudent to wait a little to see how the Company got on before doing so. The next point that I shall make a few remarks upon is the history of the 4,000 telephone contract. We have made that history a rather long one, so that you should really be made aware of all the facts of the case, and should thoroughly understand them, because, of course, we wish the shareholders to know everything about the Company, and all that has taken place in it, and therefore we made this as full as we possibly could. But I think I should just like to tell you in as few words as I can what my idea is, and I believe I may say that the committee hold the same opinion as myself. It is this: that Colonel Gouraud, Mr. Bigelow, and Mr. Cargill have sold the Edison-Bell patent to the Oriental Company. The sum agreed upon was £50,000 in cash and £100,000 in fully-paid shares. On this transaction coming to Mr. Gower's knowledge, he said to the Oriental Telephone Company:—"Oh, I have certain rights over the Oriental district, and if you don't pay me, or in some way compensate me, I shall fight you." Now that naturally alarmed the Directors who were bringing out this Oriental Telephone Company. The prospect of a fight in the beginning would naturally frighten people away, and they would not get their capital subscribed. Then, as a means of stopping Mr. Gower's mouth, Colonel Gouraud, Mr. Bigelow, and Mr. Cargill, enter into a contract to take 4,000 Gower-Bell telephones from him, and this satisfied Mr. Gower apparently. The Edison party have smoothed over the difficulty, but they did not give the original sum asked, but only £40,000 and £75,000 in fully paid up shares. Time went on and your Company purchased Mr. Gower's business. In that business, amongst the various instruments your Company had to manufacture were the 4,000 telephones—that is the contract referred to. No doubt you paid a large sum of money for that. I tried to get out of Mr. Gower what the amount was, but he evaded that point. I wrote to him, but he would not say how much he estimated that contract at. You have seen in Sir Julius Vogel's memorandum that Mr. Gower at all events estimated it as being worth £20,000. Well now, gentlemen, you see also according to Sir Julius Vogel's statement that Colonel Gouraud from the first tried apparently to get the contract set aside. After various attempts by your Board to get the contract completed, the Company called the Telephone Supply Company came on the scene. Now, is it possible that the Directors for the time being inquired who that Telephone Supply Company were? Because if you turn to the report you will find that they consisted of Cargill, 198 shares; Chesten, 1; Cheston, 1; Hubbard, 299; McLeod, 1; Bigelow, 100; Edison, 200; Gouraud, 197; Grigg, 1; Kingsbury, 1; Allen, 1. Well, gentlemen, it seems to me very much like handing that business direct from the three purchasers of that contract to almost the same people, because they are gentlemen of the family that has been written about as "the telephone ring" in the *World* and *Truth*. It seems to me that if the Directors had inquired into the matter they would not have handed over the liability to the Company. I do not know whether they did inquire or not. However, the Telephone Supply Company came into existence, and they made one payment of £1,800, and then the Board allowed Mr. Gower to assign the Oriental patents, by which they practically lost the security which they held for the completion of the contract. I understand that they were advised to do so. I can hardly believe it. Difficulties then arose, and the United say that Colonel Gouraud, Mr. Bigelow, and Mr. Cargill cannot use the 4,000 telephones in the United Kingdom. Well, we have seen, according to the report, that the United, in the agreement, expressly stated that they could use them; but for all that there was some reason in the background why those telephones should not be used in the United Kingdom, and, strange to say, I have come across that reason within the last week only, and it is this: I have seen in the possession of Messrs. Waterhouse and Winterbottom a printed document, bearing date 8th of April, 1881, of the heads of agreement, and the names of our solicitors (Messrs. Mackrell, Maton, and Co.) and those of the United (Messrs. Ashurst, Morris, Crisp, and Co.) are not on that document. Attached to it is a schedule, and in that schedule are the 4,000 telephones put down as the Oriental Telephone Company's. Now, our schedule which Mr. Gower signed has got these 4,000 telephones entered as belonging to Messrs. Gouraud, Bigelow, and Cargill, London; but there is a query against them. What that query means I do not know. But, gentlemen, with the assistance of Mr. Morgan, of the United, I am going a little further into this 4,000 telephone case. I hoped from the first that we should get something out of it, but you see counsel tells us that on the evidence we have at present there is no case for you against your Directors, or any of the parties concerned; but I do not mean to let the matter drop. Now, with your permission, I will go to a more agreeable subject—that is, what we have been doing here in London and abroad in the various companies. The first thing the present Board did on coming into power was to endeavour to the very utmost of their ability to establish friendly relations with the United Telephone Company and the subsidiaries, which are the National Company, the Northern Telephone Company, the Lancashire and Cheshire Company, and the Telephone Company of Ireland, and I think, gentlemen, I can say without fear of contradiction that we are on most cordial relations with all these companies at the present moment. You will recollect that at our last meeting, on the 25th of July, I told you that we thought we could make the manufacturing business pay a little. Since then we have been further strengthened in our views on that point, because we find that there is a very large business doing in the manufacture not only of the patented articles, such as transmitters and receivers, but in no end of articles in connection with telephonic exchanges, and that principally the business has gone into other hands, and we are at this moment striving to the utmost of our power to wrest that business from those companies, and get it into our own. If we cannot get it, it will go hard with us; but I think we can. We have machinery on our works which is not to be equalled in Europe—possibly it may be at Antwerp, but that is the only place where it is equalled. As soon as we get on our legs more firmly we mean also to go to the Continent and compete for business there. There is no reason why we should be restricted to England and to our own subsidiary companies. There is plenty of work to be done if we can only get hold of the business. The only thing that I can see that will prevent our making a profit out of this business of yours is litigation on various points. I think that is really the one thing that we have to fear. I have just roughly jotted down a few figures as to the amount of money we have paid out, and how we stand at present, to show you that the Company, at all events now, is in what you may call smooth water. According to the report of May last, I think it was—the annual report—on coming into power we found that we had to pay £3,500, and there was about £100 in the bank to do it with. That was not a very nice prospect to start with. There was certainly a sum of £3,150 due from various people, but on looking carefully through that we found it consisted of a great many consignments of goods abroad, which were not sold. I think I may say that there was about £200 that we could lay our hands on. As you are well aware, gentlemen, the Board proposed that to get rid of those liabilities, and to have some further working capital, some of you should purchase River Plate debentures and shares from us. Well, I am happy to say that the River Plate shareholders then came forward in a manner that I did not expect, and took something like £2,000 worth of shares. In all we received from the sale of debentures and shares about £9,000, and we also received from the River Plate Company interest and debenture interest to the amount of £1,200 and £500 in cash, and we discounted for the Edison-Gower-Bell two bills of £600 together; and, after a very hard fight for it, we received money from Australia which they were withholding from us. In round numbers that amounted to about £1,200. That was the amount of receipts. All the debts had been paid except the solicitors' bill, which we could not settle. We were in hopes that we could make a compromise with them, but we could not do it. The debts that we paid amounted to £2,700, leaving £800 for the solicitors unsettled. We provided money for Austria £4,500, and a further sum of £1,300 for the Edison-Gower-Bell. Income tax was reduced £100, making that £240, and we have spent about £100 on the machinery. That amounts in all to £8,840, which leaves a balance of £3,360. We have in the bank at the present moment £4,333, and we have perfectly good debts owing to us for instruments we have sent out quite lately to the amount of £5,200, making altogether £9,500, so that you may safely say that your Company is perfectly solvent now, at all events. I think that is not a bad statement to make after half a year's working. Now I will say a few words about the River Plate. Someone, I cannot tell you who, sent a newspaper round to

Digitized by Google

all the shareholders of the Consolidated Company, and in it there was a statement—as if that were something very alarming—to the effect that there was an opposition company on the River Plate. I do not know with what object that was sent to the shareholders, or whether it was to frighten them or not, but it was sent. I thought naturally that the shareholders were aware that there was an opposition company on the River Plate. I am not aware that the late Board ever kept that fact in the dark; anyhow, there is the position. I should tell you, however, that Mr. John Taylor, who is the present chairman of the River Plate Board, and who has also been elected a director of this Board, has gone out to the River Plate, and with him sailed the chairman of the opposition company, and these two gentlemen have gone out there in the hope that we shall arrive at some satisfactory compromise, and the probability is, I think, that these two companies will be amalgamated. That will be a most satisfactory thing for you. That River Plate business is a very good one, I am sure of that, and the only doubt that we could possibly have was that we should fight and cut each other's throats. I believe if we could interpret aright the telegram that we have since received it means that the managing director from the other side of the water is now on his way to England with a proposal for amalgamation. I believe he is. Now, gentlemen, the Edison-Gower-Bell Company we at present have not got into our own hands. At this moment your Board has made proposals to the Edison-Gower-Bell Board, and I hope and trust that they will be accepted. If they are accepted I believe you will find they are very satisfactory for the Consolidated Company. I will say no more on that head. We are doing very well in Austria. The last report, which I received yesterday, from Mr. Kreuzer, stated that he had 810 telephones running, and in July last we had only about 605. I think that is a very satisfactory increase, and not only so but we have got plenty more people to work upon. I should further tell you that, seeing we have such a very large stake out in Austria, your Board have deemed it desirable to send one of its members out to Vienna, to personally inspect the property and see that we have got it. We think we have got it; but thinking is very different from being quite certain. That gentleman sailed last week. I have no doubt in my own mind that he will come back with a satisfactory report to us. We may, perhaps, send some notice to you of what that report may be. However, it is too far ahead to say anything about it. The next act of importance that we did in your interest was this, that our present manager having to go to New York on his own private business, we thought it a very good opportunity to open up negotiations with the great American Bell Telephone Company, so that we might, instead of fighting and squabbling, have friendly relations with them, the same as we have with the United Telephone Company. Now, gentlemen, I do not think that I have anything more to tell you, but if any gentlemen ask questions I shall be happy to answer them.

A SHAREHOLDER: What is the litigation that you referred to?

The CHAIRMAN: We have no litigation. The only little suit we have at the present moment is in Australia, which really is, I think, according to the latest advices, proceeding most satisfactorily. It appears our opponents out there are likely to compromise the matter with us, and pay the costs that we have incurred. In the telephone world, anybody who knows anything about it is well aware that litigation seems to be one of the chief factors of the business. It is an unfortunate thing for the shareholders, but a very good thing for the solicitors. We shall have no litigation with the United Telephone Company. The first resolution is, "For adopting the original and further reports of the committee of shareholders appointed on the 23rd May, 1884." That is a very simple matter, and I therefore propose that this resolution be adopted.

Mr. J. H. BUCKINGHAM said he had great pleasure in seconding the motion. Individually the shareholders must all feel that they were very much indebted to the committee for what they had done. He would not say which of the members had done the most of the work, but that collectively they had done it exceedingly well. He would add one word of advice to them, and that was to go on investigating their affairs, and when they felt they had got the right game in their hands to do what was necessary to secure it. He saw that the Directors had done him the great honour of putting his name on the Board of the Edison-Gower-Bell Company. He had not expected that compliment, but since they had been kind enough to confer it upon him he would say in return that if the Edison-Gower-Bell came into connection with the Consolidated, and if there was anything really to be got out of it, and if his services would be of any use they would be at their disposal. He thought that the committee ought to have recommended the reduction of the capital to one-fourth instead of the proposed figure, and strongly urged the Chairman to husband the Company's resources until they had thoroughly threshed out all the doubtful points now before them, and when that was done he hoped they would be able to spare something for dividends.

The CHAIRMAN said he endorsed every word Mr. Buckingham had said. The only exception he took was as to the amount of capital to be reduced. The question had been fairly considered by the committee, and they came to the conclusion that they might fairly value the assets of the Company at the amount stated in the report, which was about £170,000; though, as Chairman of the Company, he personally would have every reason to be satisfied if they were to knock down the capital to a fourth, inasmuch as it would enable him to recommend a larger dividend when the time came. They had now some money, he was glad to say, but they did not wish to spend it rashly.

The motion was then put to the meeting, and declared carried.

The CHAIRMAN next moved a resolution, "Authorising the payment out of the funds of the Company of the legal and other expenses incurred by the said committee," and, in reply to a shareholder, said that those expenses, as far as he knew, amounted to about £50.

Mr. GREEN seconded the motion, which was carried unanimously.

The CHAIRMAN: We now come to a very old story, and that is the adoption of the original report. It was a report, when I first saw it, that did not please me very much. I have very few remarks to make on it further than that of the sum in the revenue account of credit balance—£10,290—we think that £7,050 should not be taken as profit at all, for the very good reason that that was for the compromise of the telephone contract—and you must have paid a very much larger sum than that £7,050. Therefore we cannot see how it should be called a profit. We therefore propose that that should be taken as a sum which will in the future be written off against goodwill and patent rights, &c., which I think is a very prudent thing. The further profit, which will amount to about £3,200, we think might be used to write off certain items, such as depreciation of plant, bad debts, and one thing or another, as it seems that no reserves have been provided for depreciation of plant, machinery, goodwill, patents, &c. Therefore I propose our "Adopting the annual report and accounts dated the 14th May, 1884, subject to such readjustment as may be necessary in respect of the loss sustained by this Company by the compromise of the action brought in respect of the 4,000 telephones contract mentioned in the further report of the Committee."

Sir ALEXANDER ARMSTRONG, K.C.B., seconded the motion, which was unanimously agreed to.

Mr. J. H. BUCKINGHAM again paid a warm tribute to the members of the Committee of Investigation for their zealous services, and suggested that they should be rewarded with some honorarium. He thought that under the circumstances £200, to be divided as the members thought fit, would meet the necessities of the case.

Mr. PITT COBBETT seconded this proposal, and complimented the Committee on the lucid, succinct, and intelligible report which they had presented to the shareholders.

The motion was cordially agreed to.

The CHAIRMAN: It is said that virtue is its own reward, and undoubtedly your Committee of Investigation have the proud satisfaction of having been of service to you. At the same time I think they will be gratified by the substantial reward—I call it substantial, for we did not expect to get anything—which you have voted them; and in their names and in my own behalf I thank you for it most heartily. The next resolution is with respect to the appointment of a second auditor, the consideration of which was adjourned at the last meeting. We intend to leave this question entirely in the hands of the shareholders.

Mr. J. H. BUCKINGHAM proposed the appointment of Mr. Green, at a remuneration of £25, in addition to Messrs. Deloitte, Dever, Griffiths and Company, who receive £50.

The CHAIRMAN seconded the motion, which was agreed to.

The business of the ordinary meeting being thus concluded,

The SECRETARY read the notice convening an extraordinary meeting, after which

The CHAIRMAN said: Gentlemen, the first resolution we have to propose is concerning the serious matter of the reduction of capital. As you have read in the report that reduction appears absolutely necessary, and I do not think I need make any further remark on the subject. The resolution that I propose is:—"That the capital of the Company, which is now £300,000 (divided into 300,000 shares of £1 each, of which 224,850 are in issue and are fully paid), be reduced to £243,787 10s., divided into 224,850 shares of 15s. each, and 75,150 shares of £1 each, at present unissued, and that such reduction be effected by writing off from each of the said 224,850 shares the sum of 5s. per share as capital lost or unrepresented by available assets."

Mr. HENRY GREWING seconded the motion, which was carried *nem. con.*

The CHAIRMAN next moved:—"That the following alterations be made in the Articles of Association—that is to say, Article 51, for the words 'the nominal amount of the capital' substitute '£50,000.'"

Sir A. ARMSTRONG seconded the motion, which was agreed to.

The CHAIRMAN proposed that Article 87 should be altered so as to read as follows:—"Article 87. As remuneration for their services, the Directors shall be paid out of the Company's funds the sum of £1,500 per annum, and such remuneration shall be divided among them in such shares and proportions as they or the majority of them shall determine." Gentlemen, the original amount was £3,000 per annum and a sum equal to 20 per cent. of the net profits of the Company after the Directors had paid the shareholders 10 per cent. There is a feeling in the Board which has been expressed to me that, as we with our money, so to speak, subscribed largely to the £9,000, and as by our hard work we are apparently making this Company a success, you ought to increase our remuneration. £1,500 among nine gentlemen is not a very large sum, and I have stated to the Board that I would mention the subject, as they feel strongly on the point. However, what we have to pass now is the alteration of Article 87 as I have read it.

Mr. BUCKINGHAM seconded the motion, which was agreed to.

The CHAIRMAN afterwards moved "That to Article 89 shall be added the following clause:—'If he hold or accept any other place of profit or office under the Company, with the exception of Managing Director."

Major HENRY T. G. FITZ-GERALD seconded the motion, which was carried.

The CHAIRMAN: The next resolution I propose is "That Article 90 shall be struck out, and the following Article substituted therefor:—'Article 90. No Director shall contract or be personally interested in any contract with the Company; but no contract or arrangement entered into by or on behalf of the Company with any company or corporation of which any Director shall be a member or officer shall be avoided, nor shall any Director being such member or officer be liable to account to the Company for any profit realised by any such contract or arrangement by reason only of such Director holding that office, or of the fiduciary relation thereby established, and such Director may vote in respect of any such contract or arrangement.'"

Mr. A. H. BAKER seconded the resolution, and it was also agreed to.

Digitized by Google

The CHAIRMAN finally moved that "Article 112 should be struck out," which was seconded by Mr. BAKER, and carried.

A vote of thanks was accorded to Mr. Fitz-Gerald for presiding, and the proceedings terminated.

Swan United Electric Light Company (Limited).

The adjourned meeting of this Company was held on Tuesday at the Guildhall Tavern, Gresham-street, E.C., for the purpose of considering the re-election of Directors, or the appointment of others in their places.

Mr. JAMES STAATS FORBES presided, and said: In conformity with the determination of the proprietors at the last meeting we stood adjourned for a week. Proper notice was sent out, which I dare say every proprietor has had, stating that to-day we should reassemble for the purpose of considering the re-election of Directors. I dare say the proprietors who were present will remember exactly how it stands. A wish was expressed on the part of considerable proprietors present that they should have the opportunity of suggesting—not the re-election of retiring Directors, but the introduction of what is usually called new blood. Well, we felt on this side of the table that that was a rational request, and at the end of some discussion it was determined the meeting should be adjourned for a week that the leading proprietors might meet and might come here prepared to propose either at their discretion the re-election of the retiring Directors or such names as they considered would fairly represent the leading proprietors, or a considerable section of proprietors, and would be useful to the Company in strengthening the Board, and give greater confidence to the general body of shareholders. That being the business of the meeting, I shall be very glad to hear what the representatives of the leading proprietors have to say.

Mr. SWAN: Mr. Chairman and Gentlemen—I do not think that my position as a director disqualifies me from suggesting a course of action at this meeting. What I rise to propose is, that the meeting should re-elect the three gentlemen who retire by rotation—Major-General Trevor, Mr. J. C. Stevenson, and Mr. Villiers. In recommending this course of action I feel that I may as well use an argument which was used at the last meeting by the Chairman, that "it was not well to swap horses while crossing a stream." But, in addition to that I must add this, that I conceive that the business of our Company—in which I am as deeply interested as any of you, probably more so, for I not only have a pecuniary interest, but an intensely important moral interest—has suffered very greatly from the circumstance, a perfectly inevitable circumstance, that at the outset there were no persons who were acquainted with the business. We had to start the management of the Company by means of Directors who, from the necessity of the case, did not understand the kind of work which had to be done. I believe that the slow progress that the Company has made, and mistakes if you like also, have arisen entirely from the inexperience of the Directors, the inevitable inexperience, because at the time there were not Directors to be had who were acquainted with the business of electric lighting. I think if we now choose other Directors who have not had an apprenticeship to the business, we should be sacrificing the very valuable experience which has been obtained on this Board, and which is certainly calculated to promote the success of this Company. In addition to that you could not find three men who have all the other qualifications which the three retiring Directors possess—I mean the qualifications of general competence and assiduous attention to the details of the business. Mr. Stevenson is quite exceptional in his having a longer experience in electric lighting than probably any other commercial man in England. He was the chairman of the first formed incandescent electric lighting company in England. For these reasons, gentlemen, I propose the re-election of the three retiring directors.

General TREVOR seconded the motion. He thanked Mr. Swan for having proposed his re-election, but he should be glad to be relieved of his duties, and had only remained a Director because he was reluctant to abandon the Company while it was in trouble. He would like to say a few words with regard to their foreign business. On account of the fire that had occurred at Lille the report and accounts presented did not give an accurate statement of their prospects. They were aware that they gave Mr. Swan £110,000 for their foreign patents; in the two years and three months the Company had been in existence that had only been increased by about £3,000. When they took over their foreign business the manufacture of lamps was on a satisfactory scale, and the quality of those lamps was good, but unfortunately the sales were not very large. They had to meet severe competition abroad and had to compete with companies in carrying out installations and exhibitions at less than prime cost. Their customers were threatened with legal proceedings if they used their lamps, and one of their opponents went so far as to partially seize one of their factories. They contented themselves with telling their customers that they would bear them harmless in case of their being attacked; but later on they took the initiative and instituted suits against certain parties, and since then their business had prospered fairly well. The sales abroad had more than doubled, and during the last quarter, but for the unfortunate destruction of the factory, the earnings abroad would have equalled about 7 per cent. on the amount of the capital employed in their foreign business. They paid at Lille about £650 for salaries and wages to workmen, and in return they did not get one single lamp; besides that they brought from the Newcastle factory a large quantity of lamps, and the difference between that and what they could have made them for at Lille amounted to another £1,250. Further than that, if the supply had been sufficient they might have had orders for a large quantity of lamps on which the profit would have amounted to £900. That came to about £2,800, and if they deducted from that the £400 shown as loss the difference was £2,400, which would have stood to their credit on the quarter's business, but for the unfortunate loss at Lille, and that £2,400 came to about 7 per cent. on their capital. As regarded the future prospects of the business his impression was that even if the business did not expand, if they maintained the quality of their lamps at their present standard, they might safely look forward before very long to a very fair return on their foreign investment. As regarded the English business, he did not feel himself called upon to say very much. The losses in connection with installations had not been incurred by the present Swan Board; he believed that they had not undertaken a single piece of business on which they had not made more or less profit. The only thing on which they had lost money and in which they did make a mistake was in connection with taking out provisional orders; but they thought the *raison d'être* of their Company was to carry out lighting by rentals, in the same way as the gas companies supplied gas. When London was parcelled out into divisions they took four of the best, and they had a struggle to get them. This cost them money, and by the time they got the orders and began to realise their position there had been a great fall in electric lighting shares, and they did not think their shareholders would like to be embarrassed in further enterprise, and they did not proceed. All they had done was to obtain from the London, Chatham, and Dover Railway power to light their station at Victoria, thus giving them a central lighting station for the Victoria district. It was their object to obtain that, and not to light the Chatham and Dover itself. As far as the installation was concerned, it was finished and working very successfully, and would cover expenses. They had a building large enough to light the whole district, and the machinery was sufficient to supply the whole of the stations and the buildings round about. He was now going to leave their Board, and he left it with the firm conviction that the worst stages of the Company were over, and that they had before them, though not an unclouded, a brilliant future.

Mr. DOBREE said he had an amendment to propose, but he did not move it from personal feelings. He had no doubt that the three retiring Directors had honestly done their best to successfully manage the affairs of this Company; but he represented a number of large shareholders who were not satisfied that their efforts had been crowned with success, and they were determined to have fresh blood on the Board. At the last meeting he represented nearly 40,000 shares, so that he thought that they were entitled to have some voice in the management of the concern. He moved that Mr. W. C. Quilter and Mr. Frederick R. Leyland be elected Directors of this Company, and that the third vacancy be not filled up.

Mr. VERITY seconded the amendment.

Mr. BALFOUR thought it would be the best thing for all parties to allow the three gentlemen to retire. He thought the shareholders owed a debt of gratitude to those who had come forward to take their places.

Mr. VILLIERS said that he should have great pleasure in retiring in favour of the two gentlemen proposed. The present Board had not been able during the past history of the Swan Company to bring it to the state of prosperity which they had hoped for, but he believed that it had been from no fault of their own.

Mr. STEVENSON, M.P., agreed with what General Trevor had said. The shareholders had it entirely in their power to make a change in the directorate if they chose to do so, and he had no complaint to make. He believed that the Company had seen its worst, and that it was on the road to a success in spite of all the difficulties it had encountered and might have still to encounter. He had not the slightest ambition to continue a Director if they wished otherwise. He should be glad to find that the new Board had been able to do what he had been trying to effect for a long time, viz., succeed in distributing the shares amongst the shareholders. He hoped that a change in the Board would not have any injurious effect on the litigation in several countries in Europe. He might say that since the Directors took courage to face their opponents on the Continent they had done a larger business than they did before. He might say that in Mr. Stearn, the Managing Director, they had a man in the highest degree qualified to do the work, and he hoped that that gentleman would have the loyal support and confidence of any new Board that might be appointed. Mr. Stearn had a large personal interest in the concern, and had been associated with the Swan Company from the beginning, and if he were supported he had no fear for the future prospects of the Company. He did not say that the Company would suffer from the change, but he knew that his two colleagues had rendered most active service to the Company.

Mr. KEMPSTER was exceedingly sorry that he was unable to support the very happy family arrangement which seemed to have been made. He thought it would be a most ungrateful and inexpedient thing to turn out the three retiring Directors, who he believed had done more active service than any of the others. They were turning out gentlemen who had given practical and conscientious attention to the business of this Company. There was a certain ring of large proprietors who were determined to get the matter into their own hands. He said that that might answer for the time, but not for long. It was a high-handed proceeding that would defeat itself in the end, and he was sorry that gentlemen of position and repute should have lent themselves to such an arrangement. Mr. Stevenson spoke out a little plainly at the last meeting, and it was evident that no one must speak plainly as to the proceedings of this Company if he wished to remain on the Board. Why should they not re-elect the retiring Directors and add two more to the Board? Continuous blunders had been made in this Company, but he believed that the course proposed would prove to be the greatest blunder of all.

Mr. FOSTER said that he had read the report of the proceedings at the meeting of the shareholders in the United Company, held on the 11th November, and there he observed the name of the gentleman who had just spoken. Mr. Kempster had been the cause of dissension in at least one company with which he (Mr. Foster) was connected, and when he saw

Digitized by Google

that he was taking an active part in this Company, he determined to attend the meeting, in order to counsel the shareholders not to be guided by his advice.

A SHAREHOLDER thought that Mr. Foster should not air his grievances in another company at this meeting.

Mr. FOSTER continued that he had no personal grievances, but knowing how another company had suffered he had mentioned this. He was prepared to justify what he had said, and had attended to warn the shareholders not to allow Mr. Kempster to have any hand in the management of this Company.

The CHAIRMAN: I am sure the proprietors will appreciate the motives of the gentleman who spoke last, because he desires to warn them against some other gentleman who, although he has a very few shares—I think only five—has a strong feeling and has said a great many hard words of the Directors. When you find a man proclaims that other people are very dishonest, and that he is the only honest man, all I can tell you is to look up your pockets [laughter]. The offence apparently is that the proprietors of this concern, who have a substantial stake in it, think fit to govern it themselves. Well, thank God! in companies at all events we have not yet come to manhood suffrage, where declamation, want of knowledge, and good hardihood of statement carry away a lot of unthinking people. The shareholders of this Company are men of intelligence and position, and they can judge the real value of the balderdash which Mr. Kempster has indulged in, and they will take no notice of it, but simply proceed with the business which this meeting was called to finish, because we had enough discussion at the last meeting on these general topics. I felt at the last meeting that the chairman was more or less responsible; at all events he is the figure that is to be fired at at meetings. I do not care who fires at me. I think I can take care of myself; but I did advise you then to select the Directors. I have been loyal to my colleagues, and I think if the Company had been prosperous we should not have heard a word raised as to the new blood. It is the usual thing. Men must accept jobs of this sort upon the usual conditions; if they succeed, all right; if they fail, well, they must be kicked out. I am quite open to it—I accept the position with that alternative; but in the face of the strong expression of opinion that this Company does want other men, I am not going to say a word against the amendment, and it is my business to put the amendment. But the amendment needs a slight modification in order to meet the necessary legal requirement. It will have to take this form:—"That the number of Directors be reduced from eight to seven, and that Mr. W. Cuthbertson Quilter and Mr. Frederick R. Leyland be and they are hereby elected Directors of the Company." The Articles of Association require this:—"If at any meeting at which the election of Directors ought to take place the places of the vacating Directors are not filled up, the vacating Directors, or such as have not had their places filled up, shall continue in office until the ordinary meeting in next year, and so on from time to time until their places are filled up." So that if you only elect two and three retire, you leave one not filled up, and then we should have the exceedingly invidious duty at the Board of considering who is to remain, and we should defeat the object of the proprietors that they should have time for consideration and consultation as to a further name. Therefore I put the amendment in that form.

The amendment as altered was then put to the meeting and carried.

A vote of thanks to the Chairman terminated the proceedings.

The Anglo-American Brush Electric Light Corporation.

The report of the Directors of this Corporation is as follows:—

The Directors have convened an extraordinary meeting of the Corporation to consider, and, if deemed advisable, to pass a resolution ratifying the provisional agreements entered into with the Great Western Electric Light and Power Company, and the Brush Midland Electric Light and Power Company, providing for the absorption of these companies by the Corporation, and to authorise an increase of capital to an amount dependent upon the number of fully paid shares in these companies surrendered to the Corporation; such increase, however, not to exceed in the aggregate 6,695 fully paid £5 shares in the capital of the Corporation. These are the only two British companies (with the exception of two local companies possessing sub-licenses for two towns on the south coast), which hold concessions precluding the Corporation from doing general business in the districts assigned to them, arrangements having been made with the other subsidiary companies in England (viz.: The Hammond Company, the South Eastern Brush Company, and the Provincial Brush Company) by which the Corporation are enabled to supply both incandescent and arc apparatus in their districts. As the shareholders were informed in the last annual report, the Corporation have found it advisable to take up the position of contractors, and not confine their operations as formerly merely to the manufacture of electrical apparatus; and this being the case it is desirable that practically the only limitations to the power of the Corporation to undertake work in any part of the United Kingdom should be removed by the absorption of the Great Western and Midland Companies. It is proposed to take over the business of these Companies as going concerns, thus securing to the Corporation their present local organisations, which it is believed are capable of further considerable development. The terms of purchase are in the case of the Great Western Company that the Corporation shall issue shares in the proportion of three £5 fully paid shares for every twenty £2 10s. shares, the shareholders in the Great Western Company receiving in addition out of the available funds of that company ten shillings per share in cash. In the case of the Midland Company, the terms are that the Corporation shall issue shares in the proportion of four fully paid £5 shares for every twenty-seven £2 10s. shares. The negotiations which have resulted in the above-mentioned provisional agreements have been most carefully and considerately carried out, and the Directors feel that they are justified in recommending these terms to the shareholders as fair and equitable, and at the same time as not without material advantage to the Corporation, as enabling them more effectually to carry out a policy in the future which past experience shows to be desirable. The arrangements if adopted will involve a maximum increase in the share capital of £33,475, of which £19,362 will be distributed to the shareholder in the Great Western Company and £14,113 to the shareholders in the Midland Company. For this increase of capital the Corporation will obtain not only a return of the licenses for 28 counties in England and Wales granted to these companies, but also the benefit of the operations of these companies during the past two years, from which well organised and established business may be expected to result. The Corporation will further receive good tangible assets, including cash, plant, land, buildings, &c., amounting in the aggregate, after deducting all estimated liabilities and expenses, to about £28,500, of which £4,100 consist of calls in arrear. If these calls are all paid the consideration which the Corporation will have given for the licenses and goodwill may be estimated as not exceeding about £5,000 in shares. The meeting is called in accordance with the Articles of Association for the consideration of this special business only, and as the ordinary general meeting will shortly be held, at which the accounts of the Corporation, made up to the 31st December, will be submitted, the Directors defer their report upon the general business of the Corporation and other matters.

The resolution to be proposed is as follows:—"That the provisional agreements entered into beween the Corporation and the Great Western Electric Light and Power Company (Limited) and the Brush Midland Electric Light and Power Company (Limited and Reduced), dated respectively 28th November, 1884, and 29th November, 1884, and submitted to the meeting, be and the same are hereby sanctioned, adopted, and confirmed; and that the Directors be authorised to carry the same into effect respectively with or without modifications, and for that purpose to enter into and execute all necessary deeds and documents, and to issue not exceeding 6,695 fully paid £5 shares in the capital of the Corporation, such shares to be numbered from 40,701."

NOTES.

BRAZILIAN SUBMARINE CABLE.—The cable of this company which was broken by a ship anchor half a mile from shore has been repaired.—The traffic receipts of this company for the week ended 19th Dec. amounted to £3,486.

VOLK'S ELECTRIC RAILWAY.—The Servian Commission, comprising the Servian Minister, the Mayor of Belgrade, &c., paid a visit to Volk's Electric Railway, Brighton, and inspected everything, expressing themselves much pleased with their visit.

EARTHQUAKES AND THE BAROMETER.—At the meeting on 8th inst. of the Paris Academy, M. F. Laur called attention to the coincidence of an earthquake felt at Saint-Etienne, in the centre of France, and a rapid fall of the barometer preceded by a continuance of high readings.

ELECTRIC LIGHT IN CHELSEA.—At a recent meeting of the Chelsea Vestry, a proposition was carried that the Electric Lighting Committee and the surveyor be instructed to confer with the solicitor of the Chelsea Electricity Supply Company as to the provisional order of the company.

THE TELEPHONE AT FULHAM.—At a recent meeting of the Fulham District Board of Works, the assistant clerk presented a contract with the United Telephone Company for fitting up telephone apparatus complete, on the exchange system, at a yearly rental of £20. The matter was referred to the Works Committee.

LONG-DISTANCE TELEPHONY.—M. Van Rysselberghe's experiments in simultaneous telephony and telegraphy over the line between Lisbon and Oporto, 312 kilometres = 193 miles, are reported to have been perfectly successful, while it is proposed to apply the Van Rysselberghe system to all the Portuguese telegraph lines.

LIGHTING AT ST. GEORGE'S, HANOVER-SQ.—The Electric Lighting Committee has reported that it had informed the Board of Trade that, so far as that parish was concerned, the vestry was willing that the West London Electric Lighting Company should have the extension of time they asked for securing the deposit required under the terms of their order.

RAILWAY CARRIAGES WARMED BY ELECTRICITY.—Some experiments in this direction have been going on lately at the works of M. Meritens, in the Rue Boursault, Paris. Current is generated by a Gramme machine, and produces heat in boxes externally resembling the present foot-warmers, where it is evenly distributed by a special appliance and radiated into the carriage.

ELECTRIC LIGHTING AND THE BOARD OF TRADE.—At a recent meeting of the Lambeth Vestry, a letter was received from the Board agreeing to certain modifications in the draft scheme prepared under the Electric Lighting Act, and stating that the Board would not require an undertaking to execute any specific works in any specified time, and also giving the Vestry permission to enter into sub-contracts.

LENGTH OF SUBMARINE CABLES.—*Kosmos* puts the total length of all the submarine cables at present laid at 60,000 geographical miles, about 111,000 kilometres = 68,352 miles, or nearly three times the circumference of the globe. Each cable consists on an average of 40 wires, so that the total length of iron and copper wire used amounts to twenty-five millions of miles, or ten times the distance between the earth and moon.

THE CABLE FLEET.—The ss. "Chiltern," belonging to the Eastern Telegraph Company, is now being fitted up with a view to work in a tropical climate, it being intended that this vessel shall relieve the "Great Northern" on the Zanzibar Station. The vessel is to be fitted with the electric light. The ss. "Magneta," whose launch we recorded last week, and which we intend to illustrate next week, will, as soon as ready, relieve the "Agnes" at Singapore.

ELECTRICAL TECHNICAL DICTIONARY.—A correspondent has stated that he would find very useful a complete index to *The Electrician* from its commencement; now we will state a want we have experienced, and which is no doubt also felt by many of our readers. This is a dictionary of electrical terms and those used in telegraphy, with concise definitions, and their French and German equivalents. Here is a field open for the enterprising firm of Spon, London and New York.

ELECTROLYSIS OF SOLID GLASS.—On this subject, E. Warburg comes to the conclusion that the anion SiO_3 remains practically in place; the sodium alone appears to be displaced, that of the anode entering little by little into the glass, while an equivalent quantity of glass penetrates the cathode. The re-formation of the silicate in the anode would therefore be intimately connected with the displacement of the sodium, that is to say with the passage of the current, and would not constitute a secondary phenomenon.

NORMAL MAGNETISM OF ELECTRO-MAGNETS.—P. Bakmetieff's experiments show that, in the case of electro-magnets not closed, the measure of the normal magnetism is the arithmetical mean of the intensities, C and c, of two induced currents, obtained by closing the direct and inverse magnetising circuit, that is to say $\frac{C+c}{2}$. For a closed circular electro-magnet, the measure of the normal magnetism is $\frac{2C+c}{2}$.

WEST INDIES.—Port of Spain is jubilant at the prospect of a telephone exchange. The *New Era* says it will no doubt be a welcome piece of news to the numerous subscribers who are pledged to support the new undertaking prompted by Mr. A. W. Gray to learn that the movement is now placed beyond the pale of mere speculation. Mr. Gray was expected to arrive from New York with all the necessary supplies for commencing proceedings, and it was fully expected that the new system, with its many exceptional advantages, would be in operation in the early part of January next.

"L'ELECTRICIEN."—Next year our Paris contemporary will appear weekly instead of fortnightly, as at present. "The principal object of *L'Electricien* is to place at the disposal of all engaged in this science an organ perfectly independent and free from any commercial or financial influence." More space will be devoted to practical applications, without neglecting questions of pure science. We so frequently find occasion to borrow from our contemporary that we offer our congratulations on the necessity which arises for what is practically an enlargement.

LIGHTING BY CHROMOZONE BATTERIES.—Mr. Charles Penruddocke, of Compton Park, has his drawing room brilliantly lighted by incandescent lamps, maintained by chromozone batteries. He has also fitted incandescent lamps to the pulpit and reading desk at Compton Chamberlaine Church, so that the clergyman can switch on the light at any moment he pleases. Mr. Penruddocke states that the expense is very moderate, considering the difference in brilliancy between the electric light and gas; and the steadiness of the light is remarkable. The batteries are said to be cheap, simple, and easy to maintain, and not to require changing more than once a week.

HELL-GATE LIGHT, N.Y.—This powerful light, the inauguration of which on 20th October last we duly noted, surmounts a lattice tower 250ft. high, so that, though thoroughly lighting up the roads, it does not dazzle the eyes of navigators. About 6ft. below the top of the tower is a gallery, with a slight framework above, carrying the nine lamps, which light up three-fourths of the circle. A grooved pulley and steel rope, with guided tub and counter-weight, serve for the man that attends to the lamps to draw himself up and let himself down by. The illuminating power of the nine lamps is equal to that of 54,000 candles, the current being supplied by a No. 8 Brush dynamo.

OVERHEAD WIRES.—At a recent meeting of the Marylebone vestry Mr. Endean observed that the Master of the Rolls and Mr. Justice Lindley had confirmed a previous decision in law that a telephone company was liable to pay rates to the Corporation of Manchester for overhead wires.—At a meeting of the Clerkenwell Vestry, a communication was received from the Vestry of St. George's, Hanover-square, transmitting copy of a letter they have addressed to the Local Government Board, urging it to bring the erection and maintenance of overhead wires under some adequate local authority. A resolution was adopted, concurring with the views of the St. George's Vestry.

INFLUENCE OF ELECTRICITY ON STEAM.—In a short paper on the "Influence of the electrical condition of a liquid surface on the maximum pressure of its steam in contact with the surface," in the *Journal de Physique*, M. Blondlot comes to the conclusion that "when a liquid surface is electrified, if μ represent the electric density at its surface, the maximum pressure of the steam in contact therewith is less than it would be if the surface were not charged with electricity, the temperature being the same, by the quantity $2\pi\mu^2\frac{\delta}{\Delta}, \frac{\delta}{\Delta}$, designating the ratio of the densities of the steam and of the liquid.

MAGNETIC MOMENT OF WIRES.—With the view of ascertaining the difference of magnetic moment in a solid cylinder and a bundle of wires, P. Bakmetieff filled a hollow cylinder, 148mm. long and 32mm. inside diameter, with iron wires of 1, 2, and 5mm. diameter, and magnetised them by more or less intense currents. The magnetic moment of the finest wires, as well as its specific magnetism considerably exceeded those of the two others, especially in the case of intense magnetising currents. But when, instead of filling all the free space of the cylinder, he only inserted an annular layer of iron wires, the specific magnetism of the fine wires became, from the same current, many times greater than that of the thicker wires.

BISHOP AUCKLAND.—Messrs. Duff and Rowntree are holding their annual sale of novelties for Christmas. In addition to the usual lighting by "Swan" lamps inside and arc lamps outside the establishment, they have this year added a novelty in the shape of a large Christmas tree illuminated by Swan lamps, and a powerful "Bernstein" electric lamp opposite each window, attached to movable brass pendants. This firm has been exceedingly energetic in utilising the electric light for business purposes. The "Swan" lamps in the shops and show rooms are supplied from an Elphinstone-Vincent dynamo, the Weston arc lamp from a small Siemens dynamo, and the "Bernstein" lamps from a shunt "Siemens" dynamo, all on separate circuits—an arrangement that is found to answer admirably.

ELECTRICAL VERIFICATION OF DEATH—With reference to this subject, noted in our last, M. Bochefontaine concludes that it would be imprudent to found a method of distinguishing between real and apparent death on electro-thermic phenomena. At the meeting of the Académie des Sciences, Paris, on 8th Dec., he recalled the experiments made by him in 1878 on the diffusion of electric currents in the tissues of animals, and then posed the following question:—When an animal is subjected to the influence of a Faradaic current, in a limited space, under what conditions does contact by the the fingers with another portion of the body cause a shock to the experimenter? He reminded the members that experiments made successively on living and dead animals have given variable results, even with the same current and during the same experiment.

ELECTRIC LIGHT V. DYNAMITE.—Seeing how thoroughly the waterway under Charing-cross Bridge is lighted up by the five Crompton 3,000 candle lamps fixed on the up-stream parapet, it occurs to us that, if the electric light had not been suppressed on London Bridge, there would have been great difficulty in attaching the dynamite to the pier. Might it not be worth while, in the present state of affairs, to install a few arc lamps on all the London bridges and public buildings generally? There is plenty of power running to waste, both in the stream and in the flux and reflux; and we commend to the attention of engineers as a holiday task during the ensuing Christmas the problem of studying how that power may best be practically applied to electric lighting. In this connection we may recall the fact of a high authority stating that each electric light in large American cities was as good as a policeman.

INTENSE CURRENTS.—The committee appointed by the French Government to settle the conditions to be observed in laying the conductors for high-tension currents, have to consider the following points:—1. The precautions to be taken in laying wires underground, in sewers, and above or along buildings, for being introduced and installed in interiors. 2. A set of rules to be followed by contractors charged with laying conductors of current for lighting purposes or for the transmission of power. 3. What wires, cables, and insulators it is preferable to supply for such work. 4. The resistance opposed to the passage of electric currents by wires of different diameter. 5. The maximum intensity of current that may be transmitted by these conductors. 6. The best instruments for measuring the electromotive force of the current transmitted, and a certain method for checking them. 7. The precautions to be taken for keeping workmen free from danger.

ELECTRO-MAGNETIC SEPARATION OF IRON FROM ZINC ORE.—The mining engineers of Friedric hssegen, near Oberlohustein, in Germany, have been successful in separating iron from zinc in a blende conglomerate. After a preliminary and inexpensive roasting, which renders the iron magnetic, the ore is crushed into small pieces and thrown into a hollow revolving cylinder, inside which radiating electro-magnets are arranged. The magnetic iron is attracted by the magnets and adheres to them, while the blende falls through one end into the pit. To completely separate the two ores, it suffices to repeat this operation in the same or another cylinder following on after the first. Only a quarter horse-power is required for driving the dynamos that excite the magnets, and for rotating the cylinders. Eight of these appliances treat 48 tons of ore in 12 hours, separating 7 tons of blende containing 30 per cent. of

Digitized by Google

zinc and, 18 tons of iron ore containing 38 per cent. of iron and 10 per cent of manganese.

E.M.F. VARIABLE WITH TEMPERATURE.—Helmholtz has demonstrated analytically, and Czapski has verified experimentally, the following fact, recently brought before the Paris Academy by M. Lippmann:—Certain galvanic elements have an electromotive force variable with the temperature, and also this remarkable property, that the energy which they manifest in the form of current is not equal to the energy of the chemical action measured by the calorimeter. The difference between the two quantities is due to the fact that the heat borrowed from the surrounding atmosphere is added to the chemical heat, to be transformed at the same time into electric or mechanical energy. M. Lippmann, in seeking what battery elements have an electromotive force variable with the temperature, has found that those are constant which satisfy the law of Kopp and Woestyne. Connecting this fact with M. Berthelot's former discovery, he arrives at the conclusion that, if the law of calorific capacities be verified, the chemical heat and electromotive force are equal, and also independent of the temperature. In the contrary case, the values of these properties become unequal and variable with the temperature.

TELEGRAPHING WITH DYNAMOS.—C. and E. Fein, of Stuttgart, have undertaken a series of trials with one of their 1 C double-current dynamos, as regards the application to telegraphy of this machine worked by hand, but with the intercalation of artificial resistances. The results of these trials, in which the dynamo was driven, not by hand but by a motor, which its strong construction permits, are given in the following table:—

Machine.			Morse	Instrument.
Revolutions per min.	Resist. Ohm.	Current. Amp.	Resist. Ohm.	E.M.F. Volt.
2,000	3·5	3	5,000	35
2,480	3·5	3·5	6,000	45
2,990	3·5	4·5	7,000	52
2,100	2	5	6,000	44
2,500	2	6·5	7,000	51
3,010	2	7·8	8,000	60
2,020	1	8	8,000	57
2,475	1	10	9,000	65
3,060	1	11·7	10,000	72

The Morse instrument, the electro-magnet of which had a resistance of 120 ohms, worked perfectly well under the above-named conditions.

AUSTRALIA.—A despatch has been received by the Governor from the Secretary of State for the Colonies on the subject of the resolution adopted by the Australasian Postal Conference last year respecting the proposed reduction of the charge for telegrams sent by the telegraph lines connecting Madras and Bombay with New South Wales. Accompanying the despatch is a copy of a letter upon the subject from the India Office, and according to this letter there is no disinclination on the part of the Government of India to meet the wishes of the Australasian Postal Conference for a reduction in the rates charged for Press messages on the Indian lines. So far as the Secretary of State for India is aware no objection has been raised to such a reduction by the telegraph companies interested in the matter; but it appears that Germany, as one of the administrations interested in the telegraph route to India, objects to any considerable reduction being made in the rates charged. A meeting of authorities representing the several telegraph administrations is, however, arranged to take place at Berlin in May, 1885, when the subject is to be discussed. Pending the meeting of this Conference, it appears that Lord Kimberley has no desire to raise any discussion on the subject.

EXCEPTIONAL PROPERTIES OF INDIA RUBBER.—In a note to the Russian Physico-Chemical Society, on this subject, N. Hesehus states that, in 1867, M. Govi proposed the following simple hypothesis for explaining the contraction of stretched india rubber by the effect of heat. The microscope shows that this substance is full of spherical pores filled with gas. When india rubber is stretched, these pores become elongated; if it be heated, the gas contained in them expands more than the substance, has a tendency to render the form of the cavities ellipsoidal, and thus causes the india rubber to contract. This theory has been subjected to various criticisms, notwithstanding its simplicity, and the author set about solving the question. In the above hypothesis the gas should exert its action through the variation of its expansion with reference to the pressure of the molecular forces and of the surrounding atmosphere. If the india rubber, stretched by a weight, be placed under the receiver of an air-pump, and a vacuum formed, it might be supposed that the length of the india rubber would diminish. Practical experience, however, does not confirm this supposition, as the length of the india rubber does not alter in a manner appreciable by the cathetometer, not even during a sudden readmission of air.

CAB, FIRE, AND POLICE CALLS.—With regard to our note on this subject last week, it may be well to state that some time since the Exchange Telephone Company made a sustained and strenuous attempt to introduce some such system. A complete circuit was put up at Holloway, but so little was the work appreciated that we believe not a single subscriber was obtained. The use of such a system in America is often cited as a reason why it should be in common use here; but it must be remembered that in America the call system is supplemented by a messenger system, a charge being made for the messenger. From this charge an income is derived—not from the call system of itself. In England—that is in London—the messenger system, tried and even now in existence under the auspices of the Exchange Company, has proved so unattractive that the charges for messengers alone would not pay. It so happens that other work can be done by the messenger staff, otherwise its existence would have been threatened long ago. Surely facts like these ought to cause men who speak or write for the public to consider whether it necessarily follows that because one system succeeds in one place it will succeed in another. It may be that the existence of this messenger system is insufficient enough, and we have taken this opportunity of again calling attention to it.

ENGINES FOR ELECTRIC LIGHT.—In reply to a letter asking what class of engine is best for driving electric light machinery, Mr. Powis Bale writes to the *Timber Trades Journal* that he most decidedly recommends the compound, "as it combines extreme economy in working with that regularity and exactness in motion which are necessary for effective electric lighting. The economy in working is secured in the first instance by using the steam at a high working pressure, say, 120lb. per square inch, and expanding it down to as low a point as possible before leaving the low-pressure cylinder, say to five or six times its original volume." He does not recommend a governor controlling the engine by means of the ordinary throttle-valve, as it "wire-draws" the steam. The governor should be furnished with heavy balls, and made very sensitive. A 12 horse-power compound engine, with loco-boiler, with a load of 30·26 horse-power on the brake, ran for three hours 45½ minutes with only 300lb. of Welsh coal, equivalent to a consumption

Digitized by Google

of 2·63lb. per effective horse-power per hour, or about 2·41b. per indicated horse-power, while the feed-water required was only 20·461b. per effective horse-power per hour. Mr. Bale adds that he once attempted to light a large hall in the east of London by means of an ordinary engine, but that it was found necessary to substitute a compound on account of the unsatisfactory results.

THE "GREAT EASTERN."—In the case of Lawless *v.* Pyne a motion was made last week before Mr. Justice Kay, by Mr. Northmore Lawrence, on behalf of the plaintiff, for an injunction to restrain the defendants from allowing the "Great Eastern," which is now at Milford Haven, from proceeding to New Orleans under a charter party to the defendant. The defendant is the American agent of the World's Industrial Cotton Centennial Exposition to be held at New Orleans. The plaintiff had thought of chartering the "Great Eastern" for the Exhibition at New Orleans at a quarter a dollar per head, and letting her out for balls at half a dollar per head, and intended to form a syndicate for the purpose. He entered into negotiations with the secretary of the Great Eastern Steamship Company to charter the ship, and to pay for her £6,000 or £7,000 during the Exposition, with the option of purchasing her for £45,000 at the termination. He failed to form the syndicate. The defendant, who was then in this country, but was now in America, formed a syndicate, and chartered the vessel for £7,500, and the ship was now about to leave under the charter party. The plaintiff sought to restrain the vessel from sailing on the ground that he had virtually chartered her.—Mr. Justice Kay, without calling on the defendants, held that there was no evidence that the plaintiff had ever made any definite arrangement, or that his terms had been conclusively accepted by the Great Eastern Company. The defendant had, however, chartered the vessel. The motion must therefore be dismissed with costs.

UNIVERSITY COLLEGE, LIVERPOOL.—Principal Rendall and the professors of the Liverpool University College, Ashton-street, received the day and evening students at that university on Thursday and Friday evenings. All parts of the college were thrown open for inspection, and the students, along with their lady friends, were received by Principal Rendall in the examination room, on the upper floor of the institution. In the natural history laboratories, various specimens, diagrams, and models were set out for inspection, and numerous minute animals and other objects of interest were shown under the microscope. Scientific apparatus, electrical and otherwise, were exhibited and explained in the physical laboratories by several of the professors of the college. Early on in the evening, Professor Herdman exhibited, by means of the oxy-hydrogen lantern and the microscope, a series of illustrations of animal life in the surface waters of the ocean, which exhibition was accompanied by an explicit lecture of the habits and the whereabouts of the species of life which he exhibited.

ELECTRIC LIGHT IN BIRMINGHAM.—The Incandescent Electric Lighting Company (working on the Crompton-Winfield system), which obtained an order under the Electric Lighting Act to supply current in parts of Birmingham, has given notice of a Bill in Parliament to vary the terms of the order, under which the company was required to sell the undertaking to the Corporation, as a going concern, at the expiration of sixteen years from the date of the concession (1883), and was also required to lay down certain mains within a period of two years, to maintain a constant supply of current, and to secure within six months a certain sum of money as capital for electrically lighting the assigned district. Owing to practical difficulties it has been found impossible to comply with the terms of the order, and with the consent of the Corporation, together with the sanction of the Board of Trade, an extension of time has been granted. The company now asks Parliament that the term for the deposit of capital shall be extended to two years from the passing of the Act; that power be taken to vary the assigned district from time to time, with the consent of the Corporation; that a compulsory supply of current to consumers be not required for a longer period than twelve consecutive hours; that the limit within which the commencement of supply shall take place be extended from two years from the date of the order, to five years from the passing of the proposed Act; and, lastly, that "the period within which the Local Authority may purchase the undertaking be within six months after the expiration of thirty-five years from the passing of this Act.

COMBINED ENGINE, DYNAMO, AND SEARCH LIGHT.—The French Minister for War appears to have definitely adopted two sizes of a combined arrangement of steam engine, dynamo-electric machine, and search light for guarding against night attacks, and for searching the battle-field after an engagement. The larger size includes a Brotherhood engine, with vertical Field boiler mounted on a 4-wheeled truck and a pair of large wheels; a Gramme dynamo, the armature of which makes 1,200 revolutions a minute, giving a current of 68 to 70 amperes, and a difference of potential at the terminals of 38 to 40 volts; and a Mangin aplanetic mirror. The latter possesses the same property as the parabolic mirror, that of making parallel the rays from a source of light placed in its focus, and has the great advantage over the latter that it may be ground by mechanical means. This mirror is set in the end of a short, slightly conical, sheet-iron tube, inside which is placed the arc lamp, which may be adjusted so as to occupy the exact focus. After numerous trials, it has been found possible to entirely exclude automatic regulators, and only to use hand-regulated lamps. The maximum of light, which is in this case 33,000 candles, is obtained when the positive carbon, which is a little behind the negative with respect to the mirror, has a vertical face, thus sending a flood of light on the mirror. The lamp has two carbon holders, which a double-threaded screw permits of bringing together as the carbons are consumed, so that the arc always preserves the same position—that is to say, the focus of the mirror. When the apparatus is in use, the lamp and mirror are dismounted from the carriage and placed on a convenient stand.

MECHANICAL EFFECT OF ELECTRIC DISCHARGE.—The following is a translation of the abstract, made by E. Villari, of his paper on "Singular Mechanical Effect of the Electric Discharge," published in the *Proceedings* of the Bologna Academy of Science:—When an attempt is made to pierce a sheet of thin glass by means of an electric discharge, it often happens that the spark glides over the two surfaces of the sheet without breaking it. But, if the same operation be performed on a glass plate of moderate width and silvered on one side, it may readily be broken by the discharge, although several millimetres thick. Similar results are obtained if a strong spark be made to glide over the silvered surface only of the glass. I have in this way succeeded in cracking plate glass 7mm. (¼in.) thick, some of thickest I possessed. I have succeeded in breaking two glass plates, together 16mm. to 17mm. (⅝in.) thick, placed together with their silvered sides outside, by causing to burst upon them, by means of the spinterometer, the discharge of a six-jar battery containing 96 electrical units. For the discharge to produce this pheno-

Digitized by Google

menon, it must glide over the silvered face of the plates; and the effect produced may be compared with that of a ram or hammer blow. I think I may attribute it to the sudden volatilisation of the silver layer. In fact, this effect of the discharge increases in energy with the quantity and with the potential of the charge. The edges of the glass thus broken present a conchoidal appearance; and the lines of the fractures appear to proceed from each of the two poles to the opposite face, while diverging from one another. These lines, by their direction, recall magnetic *spectra* or diagrams of lines of force.

QUANTITY OF ELECTRICITY.—M. D. Thommasi, in *Kosmos*, says that this expression, which recurs continually in practice as well as in theory, is not always understood, and requires more explicit definition, so as to avoid all misconception. It is specially in electrolysis that the "quantity of electricity" plays an important part, and with it the expressions "electrical equivalents" and "electro-chemical equivalents." Reference to the tables contained in electrical treatises show that to liberate, for instance, 4·05 grammes of silver requires a current of 1 amp.-hour absolutely, as is the case to liberate 1·05 gramme of iron, 1·19 gramme of copper, 1·11 gramme of nickel, &c. This, continues M. Thommasi, is perfectly correct, provided that in each case the number of volts accompanying the amp.-hour correspond with the quantity of heat absorbed by the decomposition of the electrolyte. This E.M.F. acquired, the metallic deposit will take place in proportion to the intensity of the current. When "electrical equivalent" is used to mean the quantity of electricity necessary to decompose a molecule of any substance whatever, it is evident that intensity of current and not E.M.F. is meant. It follows that this expression, which relates to only one of the factors of energy, seems to refer to the product itself—that is to say, to the electrical energy. To avoid this confusion, it would be well to complete the tables of electro-chemical equivalents by an indication of the *calories* of combination expressed in volts of each compound. In this way, it would be known that, for an amp.-hour to decompose 2·98 grammes of sulphate of copper, 3·02 grammes of sulphate of zinc, &c., it will be necessary that the current have at least an E.M.F. equal to 1·4 volt for the sulphate of copper, and an E.M.F. equal to 3·46 volts for the sulphate of zinc.

PERSONAL SAFETY AND ELECTRIC CURRENTS.—Professor A. E. Dolbear says: The serious accidents which have occurred within the past four or five years through accidental contacts with wires carrying strong electric currents have seemed to call attention to the necessity of providing safeguards against such mishaps. It is probable that carelessness has been the cause of most of the accidents reported, and it is true that if weak currents only were used nobody could be hurt. It is, however, worth while to consider the electrical relations of the human body, in order to learn where danger lies. I have noted in various places the opinions of different persons as to what constituted a safe current. In one of the old books it is stated a "a spark 18in. long begins to be dangerous." In another place one says that a difference of potential of 800 volts is too high an electromotive force for individual safety. Now a difference of potential of 1,000 volts will not give a jumping spark the hundredth of an inch long. The electromotive force developed by the Holtz electro machine may be as high as 50,000 volts, and the spark from it will at most give a spasmodic jerk to the elbow and no manner of hurt come of it or of repeated shocks from it, so that more than difference of potential must be considered in determining what is dangerous about electricity. The ability of electricity to do work of any kind, destructive physiological work as well as any other, depends upon both difference of potential and current strength, and the amount of work is proportional to the time also. Now, the discharge from a Holtz machine through a short wire may give a very strong current; for example, let $E = 50{,}000$ volts, $R = \cdot001$ ohm, then $\frac{50{,}000}{\cdot001} = 50{,}000{,}000$—fifty millions of amperes; but the wire may show no sign of being injured, for the time of the current passage was too short, probably less than the millionth of a second. If the discharge had continued for an appreciable part of a second the wire would have been vaporised. The discharge is probably equally quick when taken on the knuckles, but there is not enough energy to hurt anything. Again, the amount that will traverse any conductor, with a given difference of potential between its ends, will vary inversely as its resistance, and for the human body it may only roughly be calculated. The resistance of the body is very great. Many measurements, made with different individuals taking wires in their fingers and hands, gives a resistance varying between 6,000 and 15,000 ohms; but this depends in a large degree upon the moisture of the skin when contact is made. Hands which are ordinarily dry have a high resistance; the same hands moist with perspiration or purposely wetted may lose half their resistance. Dr. Stone, of London, has made many experiments, and finds that the resistance of the body may be reduced to 500 ohms or less, by having the skin soaked. On an arc light circuit with forty lamps the difference of potentials will be about 2,000 volts. If a man with a dry, thick skin were to grasp the terminals at the dynamo, the current that would go through him would be $\frac{2000}{10000} = \cdot2$ of an ampere, and in one second two-tenths of a coulomb would have traversed his arms. If the same hands were soaked, the current might be $\frac{2000}{500} =$ 4 amperes, or 4 coulombs per second. In the first case there would have been spent in him an amount of energy equal to $2000 \times \cdot2 = 400$ watts, or more than half a horse-power, and in the second case $2000 \times 4 = 8000$ watts, or $\frac{8000}{746} = 10$ horse-power in the interval of one second. Now, any electromotive force above about 1·5 volt is sufficient to decompose water, and it has been shown that the fluids of the body are better conductors of electricity than any of the tissue, even the nerves; it may fairly be inferred that such a current with such an electromotive force might decompose a notable quantity of the fluids of the body into their constituent gases. To determine the highest limit of safety would require experiments which no human beings would be willing to submit to. Animals might be employed perhaps; but if 800 volts have at any time proved to be dangerous, one may set a lower limit to the resistance of the body and determine the current strength $\frac{800}{1000} = \cdot8$ amperes. That result looks threateningly large, but it is because the resistance is made so low. I have never found one less than 500 ohms, then $\frac{800}{5000} = \cdot16$ ampere. But that represents 128 watts—a quantity of energy no one would care to have spent in him. After all, what would be safe for one would be entirely unsafe for another; so that each individual would have his own factor of safety, or the difference of potential which he could work with with impunity. From what we now know it would seem as if one-tenth of an ampere current body was as much as any one could safely have traverse his body for one second. If, then, he fixes his minimum resistance, the product of the two will give him the electromotive force which he may feel timidly safe with. Thus, if one's resistance with wet hands is found to be 8000 ohms, then $8000 \times \cdot1 = 800$ volts; while if his resistance was only 1000 ohms, he could only venture to touch wires having a difference of potential of $1000 \times \cdot1 = 100$ volts. The ordinary incandescent light circuit would be on his limit.

SILVANUS PHILLIPS THOMPSON.

THOMPSON, SILVANUS PHILLIPS, was born at York in 1851, of an old Quaker family. The Thompsons of Westmoreland and Cumberland trace back many generations, and they number, amongst various collateral branches, the family of the present Archbishop of York (who, however, dropped the "p" out of his name). The subject of this notice was educated at the Friends' School, York, an institution which has done much for pioneering scientific education. It boasts of the oldest school natural science society in existence. He subsequently studied at the Founders' College, and in 1869 graduated B.A. of London University. Having, however, a preference for science rather than literature, he studied to qualify himself for the post of science-master in his former school at York. This post he abandoned for the sake of further study of chemistry and physics, and pursued courses in these subjects at the Royal School of Mines, supplemented by visits to the University of Heidelberg and other foreign institutions. In 1875 he graduated as Bachelor of Science of the University of London, being bracketed first in Honours, and in 1878 he took the further degree of Doctor of Science, selecting experimental physics as his subject for examination. Meantime he had been acting as Lecturer in Physics in the then newly-established University College at Bristol, and had also begun to lecture under the Gilchrist Educational Trust. In 1878 he was appointed to the Professorship of Experimental Physics in the Bristol University College, a post which he still holds. In connection with this chair he has, in addition to usual academical courses of lectures, delivered courses upon the Technical Applications of Electricity upon Sound in relation to Music, and a special course of Technical Physics for Engineers and Builders. He has had the onerous duties not only of lecturing on Experimental and Mathematical Physics in the College, but of organising the Physical Laboratory of the College, a task rendered the more difficult from the circumstance that this organisation had to be accomplished in the complete absence of any available endowments for the purpose, and in the teeth of great commercial depression. His perseverance and energy, however, eventually secured success; partly by the delivery of lectures in various places in the district, and partly by contributions from friends of the College, and from his own modest salary, Professor Thompson was able to get together funds for the furnishing of the nucleus of the needful apparatus.

From the time that he entered on his duties at Bristol Professor Thompson has made important contributions to contemporary science. The reports of the Physical Society of London and of the British Association bear witness to his zeal as a physicist, and his insight as an inquirer into physical, and chiefly electrical, phenomena. His investigations range from the chromatic aberration of the eye to the form of coils in the tangent galvanometer. He is at home in the problems of binaural audition, and in the theory of the magnetic balance. The curious optical illusion known as the "strobic circles" was his discovery; and his application of the magnetic figures formed with iron filings to the illustration of electro-dynamic relations, and to the elucidation of the action of the dynamo-electric machine, are well known. The researches of Antoine Breguet were avowedly based on an earlier result of Professor Thompson's. Professor Thompson also has the honour of having applied Clerk Maxwell's electro-magnetic theory of light to the explanation of the behaviour of tourmaline crystals in their action upon polarised light; and he has even constructed electro-optic models of these crystals out of iron wire and glass. In the course of this investigation, which was largely mathematical as well as physical, he brought out a new proof of the fact—still not quite regarded by some physicists as settled—that the displacements in a wave of light are perpendicular to the so-called plane of polarisation.

Professor Thompson is, however, better known by his work amongst the applications of science than in the more recondite fields of abstract physics. His studies upon electrical storage, and upon dynamo-electric machines are known to all electricians, and have received the recognition of the Society of Arts by the award of two silver medals. His Cantor Lectures on the latter subject, delivered in the autumn of 1883, at once established his reputation of being among the foremost in the special study of the construction, theory, and mode of working of dynamo-electric machines. The lectures then read before the Society of Arts formed the first really practical effort that had been made to examine this subject with anything like clearness and a thorough grasp. They proved such a useful addition to the current literature of the subject that the reprints issued by the Society and by the publishers were speedily exhausted. They were translated into French, and in part into German. They were pirated by an enterprising bookseller in New York. This demand induced Professor Thompson to undertake the much more extended treatise on the subject recently published by Messrs. Spon, and of which a second English and a French edition is already announced. According to the critics, this work is conspicuous not only for the logical completeness of its method, and for the practical nature of its teaching, but for the thorough impartiality maintained by the author in questions of priority of invention. Almost equally remarkable has been the success of Professor Thompson's "Elementary Lessons in Electricity and Magnetism," a work which, to judge by its extensive and world-wide use, is worthy of its place beside Roscoe's "Chemistry" and Huxley's "Physiology" in the well-known series issued by Messrs. Macmillan. Professor Thompson has published several other works, including a biographical notice of Philipp Reis, whose invention in the years 1860 to 1863 of the telephone that bears his name had been almost lost sight of in the fame of later improvements, a study of Apprenticeship Schools in France, and several pamphlets on Technical and Scientific Education.

Professor Thompson is no bookworm, however. A vivacious and fluent lecturer and an eager debater, he is equally ready with his pencil as with his pen or his tongue. It is an open secret that he is often the draughtsman of his own diagrams; and he is known to his friends as an amateur artist, with a keen eye for colour. His water-colour landscapes have been seen and admired on the walls of the Dudley Gallery, and in the exhibitions of the Local Acadamy of Bristol. He possesses a library of electrical literature believed to be second only amongst private collections to that of Mr. Latimer Clark. Original works of Volta, Galvani, Franklin, and even of Gilbertus, may be found amongst the treasures thus collected.

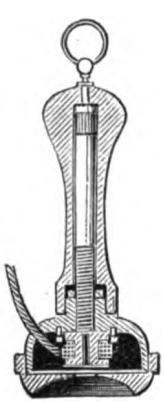
The views of the younger generation of electricians are perhaps not inaptly typified by those of Professor Thompson. He is a thorough believer in the electro-magnetic theory of light, and in the existence of electricity as an entity

Digitized by Google

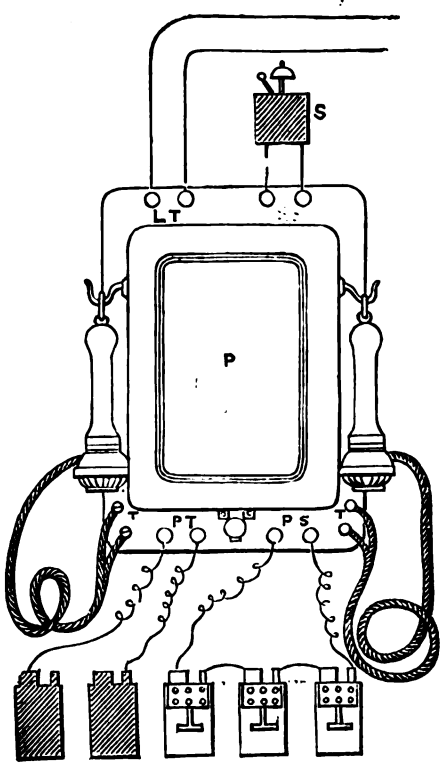
distinct from both matter and energy, though capable of being associated with the one, as also of serving as the vehicle of the other. In the dispute as to the origin and seat of electromotive force in the voltaic cell he holds firmly to the "fuel" theory—that is to say, that where the energy of the zinc, the fuel of the current, is being given out, there is the seat of the electromotive force. He spoke vigorously in the late debate at Montreal in support of this view, and exposed the fallacy introduced by Sir W. Thomson in limiting the definition of the potential of a body to the potential at some adjacent point in the external air. He regards the dynamo-machine as the central focus of electrical progress, and its relation to the science of electricity as the exact counterpart of the relation of the steam engine to the science of heat. His investigations and teaching in respect to this special subject have already borne practical fruit in various directions. Not a few of the latest forms of dynamo-electric machines may be said, without exaggeration, to bear in some point or other the impress of Professor Thompson's labours.

MAICHE'S ELECTROPHONE.

In this instrument the transmitter and receiver are now combined. The transmitter originally consisted of two distinct portions: a vibrating plate receiving the sound waves, and an organ transferring them into electric waves. The invention consists in the arrangement, on two parallel lines, of any number of carbons, separated by a certain space and breaking joint, so that the spaces between two consecutive carbons of the same line are opposite the carbons of the second row. These carbons carry others laid at right angles to the preceding, so that their ends rest on two of the carbons in the first row. The vibrating portion consists of a glass bell on which are placed the carbon contacts, as near the edge as possible. A battery current traverses all the carbons, which vibrate with the bell on speaking into its mouth. These vibrations cause differences of pressure between the carbons, and consequently induce currents in a coil, which currents are transmitted along the line for actuating the receiver. M. Maiche now uses a microphone formed of four or six diaphragms arranged in a circle, and provided with



an equal number of small bells, all included in one of larger size, the office of which is to concentrate the waves and distribute them to the small bells. The diaphragms are quite small, being cut out of thin cardboard and varnished so as to be damp proof. At the centre of each of these diaphragms, and at the back, is fixed a carbon lozenge, on which rests the contact which has to produce the microphonic effects. This contact consists of a small carbon ball, suspended by a copper wire to a jointed arrangement. The core of the induction coil is formed of a magnetised bar, the armatures being iron plates serving as telephonic receivers. The current which passes through all the contacts arrives at the primary helix of this coil. The latter, in its turn, reproduces the sounds when the transmitter is not acting, and actuates the telephones of the second station when the transmitter is in action. The circuit is thus free from telephone coils, which generally render hearing difficult. A recent improvement consists in fitting the bar (as shown by the accompanying section), not to the handle but to the mouth, by means of a screwed portion which permits of adjustment so that it cannot be displaced by the deformations of the handle. The mouth itself is of cast brass nickelised; and the nut of the screwed bar is arranged on the plate which carries the



coil. In the accompanying diagram of transmitter and receiver, S is the call-bell and battery; and P the diaphragm.

NEW ARC LAMP.

A correspondent, "G. M.," in *Kosmos* gives an account and illustrations, which we reproduce, of a new arc lamp, without, however, mentioning the name of the inventor. Although the light is not so constant as in more complicated lamps, it is said to be sufficiently so for all ordinary purposes.

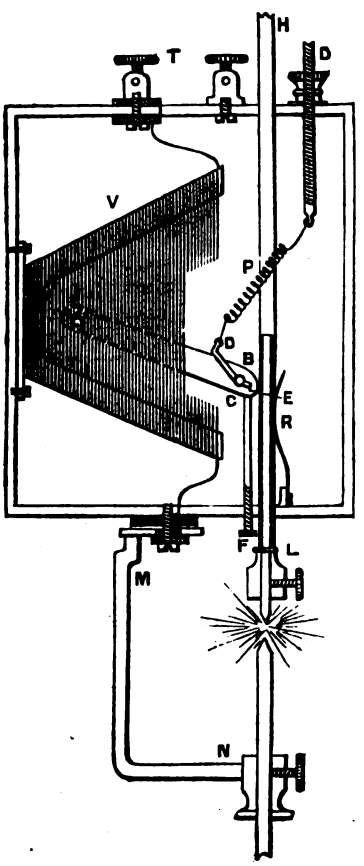
The upper carbon holder H L is a tube which slides with gentle friction in holes made in the frame or case with which it is electrically connected. The lower carbon holder M N is insulated from the frame, and is in communication with one end of the lead, the other being directly connected with the generator by means of the binding screw T, also insulated from the frame.

The mechanism which regulates the descent of the carbon holder L H consists of a brake, A B, partly shown by dotted lines; the essential portion, however, appears through a breaking away (in the cut) of part of the conical electro-magnet coil V. This brake, which forms part of the electro-magnet, is pivoted at C. It will be seen by the form given to the end B, which comes in contact with the upper carbon-holder, that, in proportion as the end A is attracted by the electro-magnet, the tube H L will be held tightly between the end B and the spring R. The position of the brake is regulated by two screws, D and F, the former acting on an opposing spring, P, and the latter on a lever, E, which limits the travel of the armature.

When no current passes, the tube H L is free to descend; and the two carbons come in contact. The lamp is then in a condition to act; but when the circuit is closed, the armature being attracted, the carbon-holder becomes fixed. It follows

Digitized by Google

that, in a second, as the ends of the carbons are consumed, the luminous arc appears between the two points. The position of the armature will have been regulated beforehand by means of the screws D and F, so that, when the carbons are no longer in contact, and the arc gives its maximum of intensity, the degree of screwing will be sufficient to keep the upper carbon fixed. When the arc tends to elongate, the intensity of the current is reduced ; and, at the same time, the attraction of the electro-magnet also diminishes The end A of the brake being then less attracted, and acted upon in a contrary direction by the spring P, will rise, thus diminishing the degree of tightness with which the upper carbon-holder is held at B. The latter will then slide, and the arc be shortened ; but at the same time the current resuming its original intensity, the brake will again act as soon as the arc attains



its normal length. The upper carbon-holder moves very slowly in exact proportion as the carbons are consumed.

CONDITIONS OF EQUILIBRIUM OF A LIQUID BAND, SUBJECTED TO ELECTRO-MAGNETIC ACTION.*

BY G. LIPPMANN.

When a liquid, traversed by electric currents, is at the same time subjected to the action of magnets fixed in its neighbourhood, electro-magnetic forces are generated which tend to displace each element of the current. These forces have their points of application in the very substance of the liquid mass. It is therefore possible, by their intervention, to realise cases of equilibrium or of more general motion than that generally presented in hydrostatics. Moreover, the conditions of equilibrium may serve to illustrate the properties of the *coupures*, which serve to render a function uniform with a given space.

Let a very thin and horizontal band of conducting liquid be traversed by electric currents brought to it by electrodes arranged in any suitable manner, and let it be at the same time placed in a vertical magnetic field of uniform intensity, H. It is required to find the conditions of this equilibrium.

* Academie des Sciences, 3rd November.

At a point of the liquid, of which the rectangular co-ordinates are (x, y), the intensity of the current is such that the components parallel with the axes are $K\frac{dV}{dx}$, $K\frac{dV}{dy}$, K being a constant coefficient and V the electric potential at the point under consideration ; V is a function of x and of y, subjected to satisfy the equation

$$\frac{d^2V}{dx^2}+\frac{d^2V}{dy^2}=0. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The electro-magnetic force is normal to the direction of the current, and therefore has for components :

$$X=-HK\frac{dV}{dy}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$Y=HK\frac{dV}{dx}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Lastly, calling p the hydrostatic pressure at the point (x, y), the necessary conditions of the equilibrium are

$$X=-\frac{dp}{dx}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

$$Y=-\frac{dp}{dy}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

What are the sufficient conditions ?

To find them, be it remarked in the first place, that from the equations (4) and (5) are obtained

$$\int(X\,dx+Y\,dy)=\int\frac{dp}{dx}\left(dx+\frac{dp}{dy}\right)dy. \quad . \quad (6)$$

It is necessary that the second member, which is no other than the equation of the hydrostatic pressure p, be a uniform function of x and y. The same is therefore the case with the first member. From equations (1), (2), and (3) are obtained

$$\frac{dX}{dy}-\frac{dY}{dx}=0. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

The condition of integrability (7) is therefore a consequence of the equation (1). In order that, besides the function of x and y, represented by the first member of the equation (6) be uniform, it suffices that the space occupied by the liquid be of suitable form, or that it be divided by appropriate separations which may be partitions impermeable to the liquid, but permeable to electricity. In that case equilibrium exists. In fact, from the equations (2), (3), (4), and (5) are obtained

$$\frac{dp}{dx}=HK\frac{dV}{dy}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

$$\frac{dp}{dy}=-HK\frac{dV}{dx} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

These equations signify that the curves $p=$ const. are orthogonal, or conjugate of the curves $V=$ const. As the values of V are given, being those corresponding with the given electric current, the same is the case with those of p. It is thus especially with the values of p along the partition.

To sum up, whatever be the form of the space occupied by the liquid and the distribution of the electric currents, it is necessary, and it suffices for equilibrium, that this space be limited by partitions arranged as *coupures*, which would render uniform the conjugate function of the electric potential. The law as to the pressures developed along the contour is the following:—These pressures have values conjugate with those of the electric potential along the contour.

It follows, then, if the given space be of simple connection, there is always equilibrium; and this is specially the case with the mercurial galvanometer which I have had the honour to submit to the Academy. Inversely, in the experiments of Faraday and the apparatus of M. Bertin, intended to show the electro-magnetic rotation of a liquid, the space occupied by it is always of multiple connection.

AFGHANISTAN.—The latest idea of the Ameer of Aghanistan, says *The Times*, is to illuminate Cabul by the electric light. It is stated that he has sent some officers to Bombay to make the necessary arrangements.

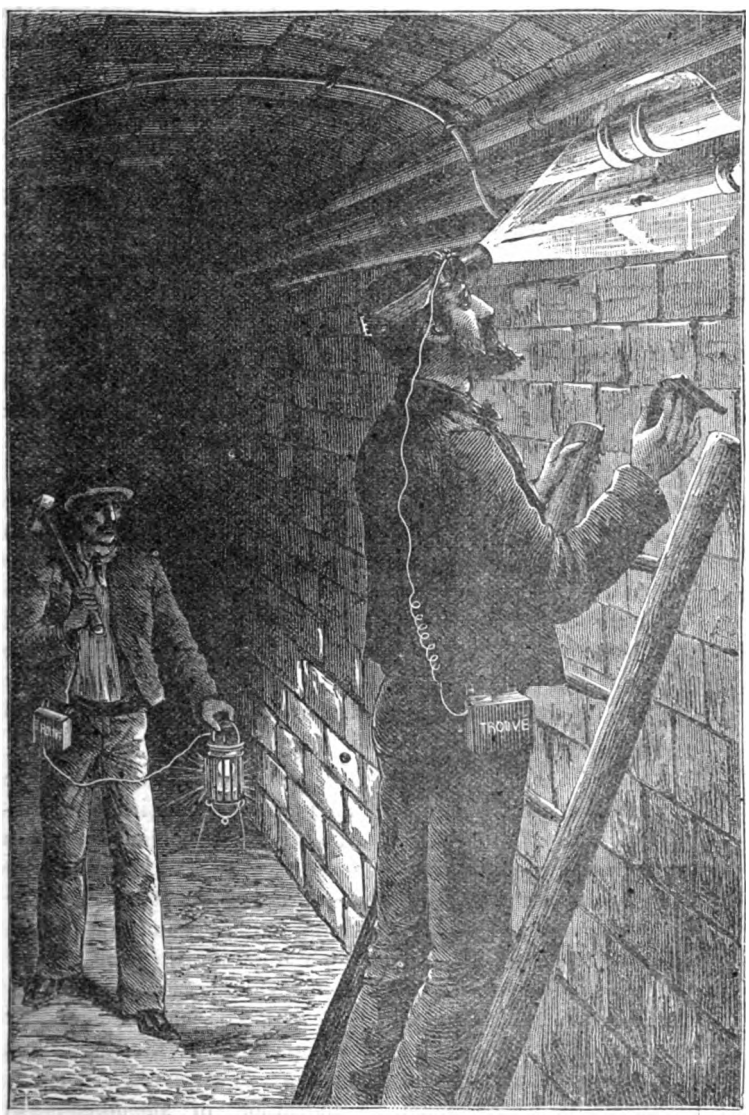
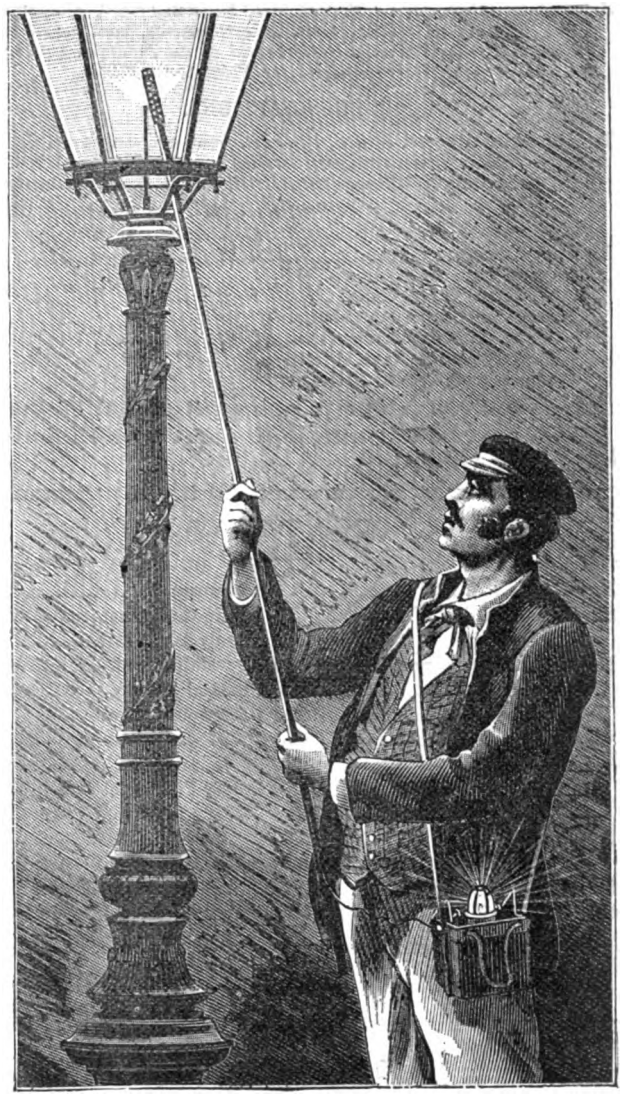
APPLICATIONS OF TROUVE'S LAMPS.

We have already described and illustrated M. Gustave Trouvé's electric jewellery and his portable electric lamps, which latter are a development of the scientific playthings, and we now illustrate some practical applications of the portable lamps.

The first view shows an *employé* of the Compagnie Parisienne du Gaz making use of the electric light under the form of an incandescent lamp, fitted into a powerful conical reflector, and worn on the forehead, so as to throw its rays on the spot to which the sight is directed. The current is supplied from one of Trouvé's portable

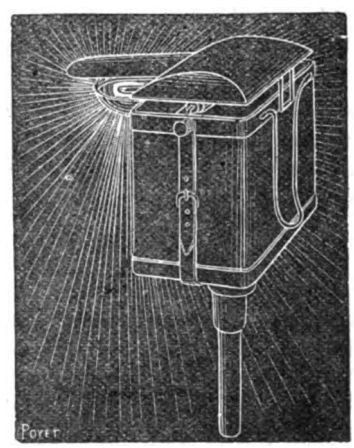




bichromate batteries, slung across the shoulder. The man is in a subway, searching for a leak in the gas main, so that it may be reasonably supposed that the atmosphere is so highly charged with gas as to be explosive; but there is no danger of ignition even if the lamp were to burst, because it is surrounded with an outer glass, while the space is filled with water or nitrogen.

The second view shows another of the Paris Gas Company's men lighting a street lamp by means of an electric lighter, supplied with current from the battery of the portable lamp slung over his shoulder, and which may be so arranged as to shine or not as required. The remaining figure shows the arrangement of carriage lamp, which is self-contained with battery, and may be used with the existing lamp sockets. The light is five or six times as powerful as that of the ordinary candle lamps, and permits, it is said, of reading inside the carriage at night. Large numbers of carriages fitted with these lamps may be seen on the Paris boulevards. There is yet another and very important application of the Trouvé self-contained portable lamps; and that is in theatres which are still lighted by gas instead of by the safer and more wholesome electric light. A few of these lamps disposed about the auditorium would be consuming no battery force until wanted; but, on an extinction of gas occurring, they would, when taken up, reassure a panic-stricken throng, and probably prevent one of those sad catastrophes of which only too many have lately occurred.

A note in *L'Electricien* on these lamps says that the domestic battery, charged ready for working, weighs 3·5 kilogrammes (7¾lb.) It contains six bichromate elements in tension, each one of which consists of one zinc and three carbon cylinders, with a provision of 100 cubic centimetres (6 cubic inches) of solution. The weight of each zinc cylinder, amalgamated with from 8 to 10 per cent. of mercury, is 85 grammes (1,312 troy grains) or 500 grammes (1·1lb.) for the six elements. The E.M.F. was found at the Ecole de Physique et de Chimie Industrielles to be 1·9 volt, and the resistance 0·35 per element. Under the conditions of maximum power they can therefore give out 3 amperes. Actually the six elements coupled



in series on the lamp yield an available current at the terminals of 8·4 volts at 1·2 ampere per element.

THE ELECTRICIAN.

VOLUME XIII.

Volume XIII. of "THE ELECTRICIAN," bound in cloth cover, price 10s. 6d, is now ready.

ALSO COVERS FOR BINDING. PRICE 2s.

TO CORRESPONDENTS.

All communications to be addressed to 1, *Salisbury-court, Fleet-street, E.C. Those relating to Subscriptions, Advertisements, back numbers of the Paper, and so forth, should be addressed to the Publisher; and those relating to Articles, Correspondence, or Notes, to the Editor.*

SUBSCRIPTIONS.

THE ELECTRICIAN *can be had, by order, from any newsagent in town or country, at the various railway stations; or it can, if preferred, be supplied direct from the office, on the following terms (paid in advance):—*

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For United Kingdom	4 11	..... 9 9	..... 19 6

SCIENCE GUILDS.

With the spread of scientific knowledge and the increased public favour extended to scientific research the relations between the guilds of learning and the outside world have been materially altered during the last quarter of a century. Or rather we should say the obligations have been altered, the fact being that their relative positions have remained unchanged, while the duties, one to the other, have undergone a complete transformation. Notwithstanding the complaints of certain grumblers at the non-endowment of science, it is an indisputable fact that the liberal expenditure of money upon scientific objects, and the popularity of scientific professors constitute an endowment which is of considerable market value, and one which, if not in excess of their deserts, is certainly beyond the highest hopes of the past generation of scientists. And this being so, it becomes a question whether the close Guilds which were founded under wholly different conditions should any longer maintain their exclusiveness and comparative isolation. We do not propose at this moment to go fully into this wide question; but briefly we may here state our conviction that in several highly distinguished quarters they seem to be unaware of the fact that they nowadays do not possess a monopoly in cultivating the fields of science, and that the fruits of their labours have ceased to be their own exclusive property.

One noteable illustration of this is furnished in the publications occasionally issued from the press of these ancient seats of learning. Their meetings are for the very elect of the scientific world, and the papers read on these occasions are presumably worthy of their audience. They are, in fact, very often of the highest possible importance; yet nobody hears them but the select few, and nobody knows of them until the period arrives, at rare intervals, for publishing the society's doings in the form of "Proceedings" or "Transactions." By that time the subjects, or many of them, have lost all their interest, and the volume containing them is so costly and so bulky that only a few people can afford either the money or the time to become masters of their contents.

Some grave inconvenience arises out of this dilatory and reticent habit, as was seen in a recent case brought to light in this journal, where an independent discovery was made and a paper explaining it read at one society, whilst a similar discovery had been made and explained a good while before at another society, but had not been announced to the public through the ordinary channels of scientific communication. It is true that by the time the second discoverer had delivered himself the first discoverer was able to point to his prior title then actually in print. It was in print certainly; but in such company, in such shape, and so long behind date that only the most indefatigable and omnivorous of readers would ever have come across it. In short, the so-called "Transactions" and "Proceedings" are mere records—valuable undoubtedly as records; but for any educational or enlightening purposes outside its own charmed circle the society might just as well keep the original manuscripts in its own lockers.

Our opinion, on the contrary, is that their doings should be made known to the public in an ungrudging spirit and without any delay. The extent to which subsidiary scientific bodies have sprung up, and the progress of scientific journalism in recent years are proofs of a widespread interest in scientific research; and there is something ludicrous in those bodies claiming to stand highest in reputation refusing any mutual intercourse either with their humbler followers or with the press, which alone can make their title to repute accepted by the outside public, and yet complaining of the public not recognising the claims of science as it deserves. We are thankful to acknowledge an indication of amendment in respect to Professor Tyndall's Christmas lectures at the Royal Institution, which by his courtesy we shall be able to report in full. This is as it should be; and we hope the example will not be lost upon other learned societies.

We cannot, however, acquit some of the subsidiary societies of faults equally grave though of a different kind. Their meetings are open enough, and their Proceedings are not inordinately delayed in publication. Neither do they discourage reporting, except perhaps when they happen to have a grudge against a particular journal. But in their organisation and management there seems very little to choose between them and their more aristocratic parent societies. The tendency to exclusiveness grows upon them; and the form it takes is to treat the members as if they did not form an integral part of the Society, or at all events to assume that its Council is the Society. Our last week's account of the annual meeting of one of these bodies illustrates what we mean. Election of new members on the governing Council is supposed to take place on these occasions; but in reality

Digitized by Google

the proceeding is a mere formality, the council nominating their successors, and the meeting ratifying their choice. Formerly they submitted several alternative names, and the members made choice; but even this small piece of indulgence has been withdrawn, and there is nothing now to be done but to vote for the Council's nominees, and try to look edified.

Members of societies governed in this way are reduced to nonentities so far as their influence on its councils is concerned. The selections may be unexceptionable; but made in this fashion they are apt to be criticised and objected to in private, and at best are not likely to secure the confidence of the whole body of members. As far as administration goes, perhaps, it matters very little; but for the selection of papers to be read, the attraction of fresh members to its fold, the introducing of fresh activities into the society, this hole and corner method of electing the administrators is decidedly detrimental. The Society of Telegraph-Engineers and Electricians, in which our readers take a warm interest, may be wise to consider this subject before another election takes places. Meanwhile, despite all shortcomings, we beg leave to wish these Guilds of Science without exception a merry Christmas and a very prosperous New Year.

CORRESPONDENCE.

THE ELECTRIC LIGHTING ACTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I observe in your last issue a list of the members of a committee promoted by the Anglo-American Brush Electric Light Corporation to confer with the Board of Trade on the amendment of the Electric Lighting Act and Provisional Orders of 1882 and 1883. A brief examination of the names and connections on that list will suffice to convince anyone that it does not fairly represent the electric lighting industry. The Anglo-American Brush Company and the Edison and Swan United Company are no doubt by arrangement in the majority, and that these two companies govern the committee is proved by the election, by ballot, of ten of those members to form the executive committee, all of whom, I believe, belong to or are connected with one or the other of the two companies before named. It is obvious that such a committee is not representative; it does not represent a hundredth part of the interests involved, and on that account, if it is to have the confidence of the body of electric light engineers and others interested, and to be in a position to carry through such alterations in the Electric Lighting Act and Provisional Orders as are considered necessary, it should be remodelled to include:—

1st. Other Electric Light Companies (in a fair proportion).

2nd. Kindred Companies, such as Telegraph Cable and Wire Companies, Steam, and other Motive Power Companies and Firms.

3rd. Private Electric Light Contractors.

4th. Consulting Electric Light Engineers, Borough Engineers, &c.

5th. Civil and Electrical Engineers generally.

It is a well-known fact that private electric light firms are doing more business in electric lighting than all the companies put together; and it is obviously unfair that they should not be represented.

In its present form the executive committee only speaks for the two companies, viz., the Anglo-American Brush Electric Light Company (Limited), and the Edison and Swan United Electric Light Company (Limited), and only represents company interests, at present the weakest of all the electric lighting interests; and unless the committee be remodelled I would advise the private firms and others I have indicated to form a committee to look after and advance their own special interests. I should like to know how the committee will work with that appointed by the "Dynamicables." The "Dynamicables" have produced a very excellent and well-timed report on the subject, and they are far more representative than the two companies can ever be.

At a recent meeting of the "Dynamicables" I pointed out the advisability of their working and presenting their report in conjunction with the Institution of Civil Engineers, the Society of Telegraph Engineers, and other such well-known and established societies. I would suggest that instead of the disjointed and weakened efforts of special and independent committees, that the proper and most forcible way of obtaining the repeal and alteration of the Electric Lighting Act and Board of Trade Provisional Orders will be by a combination of the companies' committee, the "Dynamicables," and as many of the undermentioned institutions and societies, and such like, as may be induced to join, viz.:—The Institution of Civil Engineers, the Society of Telegraph Engineers, the Royal Society, the Royal Institution of British Architects, the Society of Engineers, the Society of Arts, the Iron and Steel Institute, and others, the arrangement and management to be placed in the hands of the "Dynamicables," who have shown themselves eminently qualified for such a position. Such a combination, representing, say, 50,000 men all more or less specially interested in the subject, would be all-powerful to fight the large competing interests of the gas companies, and to deal with the local authorities. The labours of such a combination would be treated with the respect due to the large body of the best class of men in the country they represent. I submit that all the societies mentioned, the companies and private firms who all desire the advance of electric lighting, would assist in such a combination, and help us to get out of the present slough of despondency, brought on by disreputable company mongering and interested cliques. The favourable revision of the Electric Lighting Act and Provisional Orders is necessary, and would materially help the electric lighting industry, and no doubt lead to the public lighting of large areas. The interests involved in such work are enormous, and it behoves all who wish to share in the prosperity in prospect to unite to prevent the combination of any two or more companies from practically arranging the terms to suit their own special schemes, and monopolising the advantages at the same time, with very doubtful chances of ultimate success in securing alterations at all. On the other hand, a combination such as I have outlined would have the confidence of every one, and would, no doubt, be able to secure the alteration in the Acts and Provisional Orders we all so much hope to see. May I request your own views on this all important matter?—Yours, &c.,

HENRY F. JOEL.

Tower Chambers, Moorgate-street, London,
E.C., Dec. 22, 1884.

THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of 13th inst., p. 82, under the notice "Catalogue—Messrs. King, Mendham, and Co., &c."—there appears to be a grave error in the description of the Wimshurst machine, as follows:—"The electricity is collected from these straps by wire brushes, &c.," to end of paragraph. This whole paragraph is entirely wrong, as the only apparent office that the wire brushes perform is to put two opposite strips of brass on same diameter of disc into electrical connection, twice in each revolution, and which is essential to the working of the machine. The collectors are entirely separate, and on the horizontal axis of the plates, and may be removed without affecting the working of the machine, and if so removed the electricity is given off from certain parts of the plates in a copious brush discharge, and the peculiar smell of ozone is very perceptible at a considerable distance. In order to obtain the maximum effect, it is necessary that the two rods carrying the brushes should be set at an angle of 45° from the horizontal axis of the discs, and at right angles to one another; and by revolving the plates

Digitized by Google

in the contrary directions, the electricity will be produced in the two vertical sectors of the plates, and not in the horizontal sectors. The same may be done by altering the position of the brushes and revolving the plates in the original direction. I have a machine, more or less made by myself, with plates 19½in. diameter, with twenty pieces of brass on each plate, and as each plate revolves 200 times per minute, the pair of collecting combs, connected with each electrode, take electricity from no less that 8,000 pieces of brass per minute. The machine is a most interesting one, but I am unable to explain its action, though it is said to be on the principle of the electrophorous; at any rate, its efficiency is remarkable, and it seldom reverses its polarity, but its construction is attended with many mechanical difficulties. The machine that I have is made very substantially, and mounted on a special table with an arrangement for a lamp to dry the plates in damp weather, and with this lamp I have no difficulty in working the machine in all weathers and obtaining good results even in a close and crowded room. I do not see why the machine should be called "Influence." I should have thought Inductional would have been a better term.—Yours, &c., W. KNIPE, Lieut.-Col.

POCKET ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

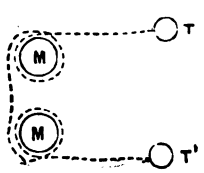
SIR: Having noticed that one of your correspondents asks (in to day's issue of your paper) where he can obtain a pocket accumulator with scarf pin, permit me to enclose you my price list for these. I may mention I am supplying some electrical effects for Mr. Augustus Harris's pantomime at Drury Lane Theatre.—Yours, &c., H. BURY.

27, Arcade chambers, St. Mary's Gate,
Manchester, Dec. 20, 1884.

WINDING FIELD MAGNETS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: All the text-books on electricity that I have read, as well as those treating of dynamos from a theoretical point of view, differ from those books which treat of the dynamo practically as to the method of winding the F.M. coils, the former stating that the wire must make an **S** curve in going from one arm of the magnet to the other, whilst the practical treatises show that, looking at the magnet from the poles, the wire is wound the same way round on both arms thus :—



at the same time marking the poles N. and S.

Will you please inform me through your valuable journal—first, the practical advantage of one method over the other; and second, how the latter method is consistent with Ampère's "Memoria Technica."

I may perhaps mention that both these methods are shown in *The Electrician* present volume—the former in page 270, Fig. 1, page 280, Fig. 4, and page 364, Fig. 22; and the latter method in page 255, Figs. 4, 5, and 6.—Yours, &c.,

A STUDENT.

December 18th, 1884.

REDUCTION IN TELEGRAPH TARIFFS.—The telegraph companies to Australia, in conjunction with the Indian Telegraph Administration, have almost arrived at an understanding for an agreement reducing the charges for Press messages to Australia to a quarter of the present rates, in consideration of the Press guaranteeing a certain amount of revenue. A similar arrangement with reference to Indian Press messages is under consideration.

LITERATURE

Magneto-Electric and Dynamo Electric Machines. By Dr H. SCHELLEN. Translated from the 3rd German Edition by N. S. Keith and P. Heymann, Ph.D., with Additions and Notes by N. S. Keith. Vol. I., with 353 Illustrations. [New York: D. Van Nostrand. 1884.]

A short time since we gave a first notice of Professor S. P. Thompson's work on dynamo-electric machinery. The work now before us traverses somewhat the same ground as that of Professor Thompson's, so that we are getting rapid additions to this class of literary production. We have no intention of comparing these works, because it seems to us that the authors had not exactly the same object in view.

Let us in the first place bear testimony to the care of the editors, and direct special attention to the additions of Mr. Keith. These additions in almost every case are as valuable, and in some cases more so, than the original text. The translators have one paragraph in their preface which should be studied by all visitors to the Patent Office. They say:—"A change of a screw here, a shaft there, an alteration of field-magnets, a long or a short armature, in endless variety, does not make a new machine, though a new name may be given it."

Before describing the various machines, the elementary principles of magnetism and electricity are discussed and explained. In the first part we have the usual diagrams illustrating the direction of the lines of force in bar magnets, the solenoid and the Ampèrean theory, followed by paragraphs upon induction and the action of currents and magnets upon currents and magnets. The next chapter describes the best known form of dynamometer, galvanometer, meter, &c. We never lose an opportunity of declaiming against the lack of an acknowledged universal notation, and this chapter gives us an example, thus:—

$$A = \frac{\text{volts} \times \text{amperes}}{735{\cdot}7}, \text{ or } \text{H.P.} = \frac{\text{volts} \times \text{amperes}}{C}.$$

In the first expression A stands for horse-power, in the second C stands for a constant. Why should C in electrical formulæ now indicate current, now capacity, and now a constant? A couple of pages further the same letters are used to indicate something else, and we have I indicating current as in $I = C\sqrt{A}$, while two pages further C is used to indicate current in $E = R \times C$.

We now come to the most important part of the work, viz., those chapters describing the various machines. Part III., or, as we should call it Chapter III., deals with magneto machines from Pixii to De Meritens. Of this chapter and of the following chapters there is not much for us to say. Most of the machines have been described scores of times, but we do not think any better descriptions will be found. The interpolations of Mr. Keith are often interesting—historically as well as practically. We do not remember to have seen anywhere set forth more clearly the claims of the early workers in the dynamo field. The papers of W. Siemens in the February number of *Poggendorff*, 1867; of C. W. Siemens to the Royal Society, Feb. 4, 1867; of C. Wheatstone to the Royal Society, Feb. 14, 1867, so often referred to in the history of the development of the dynamo are here given, as is a letter from Professor M. G. Farmer, and an extract from the *Proceedings* of the Literary and Philosophical Society. Further on we have a full translation of Dr. Pacinotti's paper in "Il Nuovo Cimento," July, 1864. This portion of the work is entirely due to Mr. Keith, and he deserves our warmest thanks for printing these papers.

We have said the descriptions of machines are good; the same may be said of the illustrations.

The theory of dynamo-electric machines forms the concluding part of the book. The works of Frölich, Deprez, Thomson, Ayrton and Perry and others, form the basis of this part.

The Disc: A Prophetic Reflection. By E. A. ROBINSON and G. A. WALL. [London: Griffith, Farran, and Co., 1884.]

The internal evidence savours strongly of an American origin for this book, and still more strongly of ignorance

Digitized by Google

regarding the fundamental laws of science. Here is the tale :— Two college chums meet after some years' separation. One knows an inventor whose secrets in the hands of the other may lead to wealth. The inventor, wedded to science, so managed that his wife ran away, leaving a daughter to the tender mercies of the scientific recluse. The daughter, however, takes after the father, and so far all is well. John Alder, the inventor, meets the two friends, shows a wonderful discovery, by means of which light, sound, and heaven knows what may be transmitted by electricity, the apparatus consisting of a "disc," wires, and other electrical paraphernalia. Sunshine can be thus transmitted, then we have a wonderful light from some chemical plastered upon the wall, and so on. A joint stock company is formed to promote and work the photo-electrophone, which proves very successful. The old inventor has steadily refused to leave his shell or take part in business matters, all being left to the two young men, who are pledged to keep his home a secret. A new man appears upon the scene with a wife and handsome daughter. One of the chums has already bespoke the daughter of the inventor, the other does as much for the new introduction. The new man is elected a director and becomes an active worker. The inventor is perfecting another invention to eliminate disease and restore youth. His experiments are seen through the photo-electrophone by his daughter's betrothed and also by the new director. The latter recognises the inventor, who is in reality the true husband. Of course the situation is now fairly startling; but the inventor is killed off, his secret for the renovation of youth dies with him, marriages are made, and all is happiness. The photo-electrophone is a grand success. Those who think this sketch interesting had better get the book, it may while away a winter's evening, though a word of caution might be given to consider the novelist's ideas as pure invention, founded upon no scientific truths, nor to be regarded as possible or probable in the manner indicated. What science may have in store for us we do not know, but at present we draw a line at bottling up sunshine in America or in Asia and electrically transmitting it to light up Lombard-street and the Poultry.

LUMINOUS PHENOMENA OF ELECTROLYSIS.

If acidulated water be electrolysed by an intense current—1 to 5 amp.—with the aid of two platinum wire electrodes, and the circuit be closed by slightly immersing the cathode, a greenish light will appear at the cathode, an energetic disengagement of gas ensue, the platinum and the liquid become heated, and the force of the current diminish considerably. If the current be rendered sufficiently intense, the noise will suddenly cease, the light become stronger, and the liquid assumes a spheroidal state, leaving the cathode, and forming round it a kind of funnel.

During the continuance of this phenomenon, gas will be disengaged normally at the anode; but, if the immersed surface be diminished, the action will be reversed, provided the current be sufficiently intense. The Russian *savan*, Slouginoff, has inquired into the conditions which determine the production of this kind of abnormal electrolysis, its causes and effects, and arrives at the following conclusion :—When the platinum of the cathode has closed the circuit by its contact with the liquid, the elevation of temperature at the point of contact may become sufficiently great to evaporate the nearest particles of the liquid in such a manner as to again interrupt the circuit. The extra current increases the effect which is reproduced the following second, when the liquid, thrown off by the vapour generated, again comes in contact with the cathode, in such a way that the intermittences of the current are repeated indefinitely. A greater intensity of current produces a truly stable spheroidal condition. This explanation is borne out by a series of facts, ascertained by experiments, of which the following are the principal. A telephone, placed in one branch of the principal circuit, or in the secondary circuit of a Ruhmkorff coil introduced into the principal circuit, causes a more or less loud sound during the abnormal, energetic electrolysis; but this sound becomes scarcely perceptible while the spheroidal state continues. The introduction of a coil into the main circuit, and also that of an iron core into this coil, increases the intensity of the sound, while at the same time lowering the note; and the extra currents, intensified by the coil, permit of the phenomena taking place with a less number of elements. Kœnig's revolving mirror decomposes the light of the electrode into a series of sparks, the configuration of the image showing that the sparks succeed one another round the electrode along a trajectory in the form of a spiral. The luminous electrode is quickly disaggregated, the liquid after the experiment containing a black powder, which is found to be platinum black. The spectrum of the light from the cathode is continuous; and in the case of very intense extra currents a few platinum lines and traces of the hydrogen spectrum may be seen.

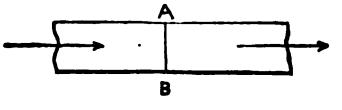
If a solution of chloride of platinum, gold, or silver (in the hydrochloric acid) be adopted for the electrolyte, a very vivid light is obtained, produced by the incandescence of the powder from the reduced metal, which, after the experiment, is found suspended in the liquid.

THE HALL EFFECT.

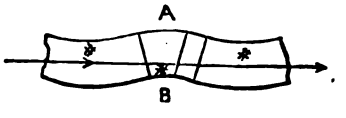
The following is Mr. Edwin H. Hall's paper, with discussion thereon, read before the American Association in Philadelphia during September :—

On the Magnetic Rotation of the Equipotential Lines of Electric Currents in Various Metal and Alloys.

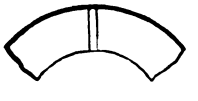
New interest has probably been awakened in the discussion of an alleged phenomenon by the objections which have been made during the last six months by one or two gentlemen in England, notably Mr. Bidwell, who has attempted to explain by the effect of strain and thermal currents the phenomenon which for the last three years has been considered a new manifestation of electrical effect. I think it worth while to give a sketch of Mr. Bidwell's explanation of the phenomenon. If this is a strip of metal through which a current is passing in the direction of the arrow, the strip will be crossed by equipotential lines as A B.



If now a magnetic force is produced, acting perpendicular to the plane of the strip, it is subjected to a strain, which forces it into this condition :



In the marked portions, the compound action of the magnetic force and the electric current tends to lift the magnetic field. The portions not marked are relatively stretched with respect to the others. I do not stop to discuss whether this strain exists. If it does occur, Mr. Bidwell says this will take place. The compressed copper is thermo-electrically negative with respect to the stretched copper, so that as the current passes across from the compressed portion to the stretched portion there will be a heating effect; and as it passes from the stretched to the compressed portion there will be a cooling effect; so that we shall have here at the top, first heat and then cold, and at the bottom first cold and then heat. The effect is to shove the two equipotential points A and B, to make this point practically nearer this end of the plate and this point practically nearer the other end of the plate.



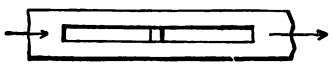
To meet this I change the conditions of the experiment. Instead of fastening rigidly to a strip, I simply took a strip of steel and arranged it so that I could clamp it at the ends, or across the centre, leaving the ends free. Now, if in the first experiment the tendency of the magnetic action were to lift the plate, when we have the clamp in the centre, we should expect it to be forced in something like this condition by a similar action; that is, an action which would tend to lift the whole plate.

Digitized by Google

Trying that experiment with the clamp at the centre and again at the ends, I found the result to be the same whatever the position of the clamp, and the equipotential lines to have the same direction as when the plate is imbedded in a firm piece of cement.

In my first publications upon this matter I did not state whether the magnitude of the effect was the same when the plate was clamped at the middle or ends; my experiments were too rough to determine that. They appeared to be of the same magnitude. I have since compared a plate of steel, clamped at the middle only with a similar plate of steel imbedded in cement. Under these conditions I think we should expect, under Mr. Bidwell's explanation of the phenomenon, that the effect would be seriously modified, if not in direction, at least in magnitude. I did not find any such modification as that. My experiments were not accurate enough to enable me to say that the effect was absolutely the same when I was using the clamped plate as when I was using the plate imbedded in cement; but it does not vary more than ·1 per cent., if it varies at all.

There is another experiment which Mr. Bidwell has published, which seems to be of considerable interest, and to require an explanation from me. It is what he calls a reversal of this effect. He does not obtain it in any simple way, as I think he should obtain it if his theory is correct, by clamping the plate at one place or another, and so change the strain; but he gets what he calls a reversal of the effect in this way:—



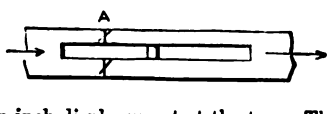
He makes a plate with a slit in it, and a narrow piece of gold making connection across the slit.

He connects the equipotential points with a galvanometor, tests as before, and finds that the effect upon those two points is not so great as before this slit was made. This, he says, is contrary to the explanation that had been given before of the phenomenon.

I wish to say just here that I do not know that any one has a right to talk of the "supposed explanation" that I have given. I have not seriously attempted any explanation of the phenomenon. I have simply stated the fact that the equipotential lines are turned in that direction by the magnetic action, instead of running straight across.

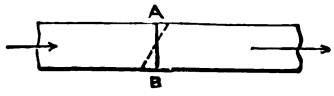
When Mr. Bidwell connects a point there with a point there (indicating) he gets an upward current, and that, he says, is a reversal of the effect.

This strip is practically two strips, connected by this little arch. In fact Mr. Bidwell himself stated that it would be so. Remember that all I claim is that the equipotential lines are rotated to a certain extent from the vertical. With a given magnetic force and given intensity of current passing through the strip, the upper line will be rotated about its centre,



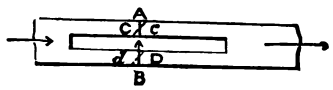
so as to give, say, an inch displacement at the top. The other line below will be rotated through an equal angle about its centre, and the displacement of its lower point would be one inch.

Let us take the entire piece, with no slit in it. We have the points A B, as before, and the line joining them is rotated through the same



angle that the shorter lines A C, B D were rotated through, and we get practically a displacement of two inches. We should therefore expect the effect to be about twice as great in this case as in that.

What would be the effect if we bridge this slit? It would not entirely restore the condition of the whole plate. Suppose—this slit remaining unbroken—you were to connect a point there *c* with a point down there *d*. This point *d*, being at the left of that line B D, means that it is at a



higher potential than any point on that line, and this point *c* being at the right of that line C A, means that it is at a lower potential than any point on that line. But these two lines B D, C A being equipotential lines, the consequence is that this point *d* is at a higher potential than that point *c*, and the current, flowing always from the higher to the lower potential, will be in this direction, *d c*. Putting in a narrow bridge will not entirely destroy that effect. That, I think, is a sufficient explanation of what seemed a very damaging experiment by Mr. Bidwell.

The new points which I have obtained with reference to this matter are not very startling, and, as they will appear in print before long, I shall not discuss them.

However, with reference to the effects of temperature, in all magnetic materials (whether the effect in them be positive or negative) the effect of a rise of temperature is to increase the transverse effect. Mr. Tomlinson has discovered relations from which he predicted that in nickel the angle of transverse effect should decrease with rise of temperature, and he questioned my conclusions in regard to that matter, saying that my experiments were not entirely satisfactory. I agreed with him, and so I repeated the experiment this summer with considerable pains, and the conclusion is the same as before. The effect in nickel is decidedly to increase the transverse effect about 2-3rds per cent. for a rise of one degree between 23, 24 and 24, 25. There is also a considerable numerical increase in the transverse effect with iron, steel, and cobalt. With respect to the non-magnetic metals, although I cannot speak with certainty with respect to any of them, it appears that an increase of temperature gives a slight decrease in the transverse effect. There is only one apparent exception—one of the alloys of copper and zinc.

Sir William Thomson: When I first heard of Mr. Hall's discovery it appeared to me to be a discovery of a most important phenomenon, in fact one of the most important discoveries of this century in respect to magnetism. The phenomenon belongs to the general class of rotational phenomena the theory of which falls under the very general subject in dynamics of gyrostatics. Mr. Hall's discovery interested me particularly, as it brought out in fact a result that had lurked in mathematical formulæ from about the year 1856, if I remember right. In a reprint, which appeared about a year ago, of a paper on "The Electro-dynamic Energies of Metals", and of another on thermo-dynamics, published respectively in the *Memoirs* of the Royal Societies of London and Edinburgh, I called attention to the fact that now Professor Hall had demonstrated by experiment the result which lay there in those formulæ, and which was referred to there as a thing to be looked for by experiment, the thing had been pronounced, even by so great an authority as Professor Stokes, to be improbable, because it was so unlike what we know of the general properties of matter. Still, it seemed to me that the dynamical foundation in the essential properties of energy connected with magnetism being there, we must not, because it seems unlike what we know of the distribution of heat through crystals and such other phenomena, therefore assume that it was non-existent. I did, in fact, myself make an exceedingly slight and unsatisfactory attempt to obtain the result. I obtained no conclusion whatever, but left the thing as I found it, demonstrated as a proper mathematical result of magnetic influences, but not yet discovered by experiment. It was therefore to me that the matter was of exceedingly great interest when I found it was discovered by Professor Hall.

The explanation which Mr. Hall has given of Mr. Bidwell's ingenious last attempt to disprove the result is very interesting, and we see that Mr. Bidwell's attempt to explain away the phenomenon is only curious, and not in any sense important. It struck me that there was another way than that which Mr. Hall put before us of making a crucial experiment to test whether or not there was anything in the kind of action indicated by Mr. Bidwell. The experiment might have been made in this way: take a strip of material and apply independently a mechanical strain, which may be made without disturbance of the electrical balance, and to be made much greater than the strain invoked by Mr. Bidwell for explanation. Has or has not Mr. Bidwell's attempted explanation been tested by applying a mechanical force pulling to one side? That should give a far greater result than the very small magnetic stress assumed by Bidwell.

Professor Silvanus P. Thompson: I think the experiment was tried by Mr. Bidwell with success. I am not positive about that, but I believe that was the case. I do not know how great a force he applied.

Sir William Thomson: It is quite clear that Mr. Bidwell's suggestion is apposite to the thing. It is the suggestion of a thing that would produce the effect that Hall has discovered. It is itself founded on the gyrostatic property that transverse force which we know to exist will induce qualities which indirectly will have an effect upon Hall's result. So, though I have spoken somewhat slightingly, perhaps, of Mr. Bidwell's suggestion, I do not wish to do so altogether. It is very ingenious. I would think it worth while to go into an examination of the kind of action involved in Mr. Bidwell's suggestion and compare that with the magnitude of Hall's action. Mr. Bidwell's explanation would make it a matter of time. It would be some time before the metal becomes heated; whereas it seems that the property may be an instantaneous one connected with the instantaneous existence or non-existence of the force.

Mr. Hall: Yes, sir. And not only that, but it would depend very greatly upon the surface condition of the metal; for example, whether the strip was exposed to the air, or imbedded in the resin and beeswax. My experiments also show a very great range of conditions as to the temperature, with no corresponding change to be observed in the effect.

Sir Wm. Thomson: It seems, in fact, that Hall's statement, that he has experimented with a variable clamp and observed no difference, is quite decisive against Mr. Bidwell's theory. Let me point out a mechanical model of Hall's phenomenon. It is very far from fitting exactly, but that it does contain the essential, fundamental principle of Hall's phenomenon I cannot doubt. Let us suppose you have here a circular canal of water on a turning table which may be going around once in five or ten seconds. Suppose we have a large turning table so that it could be done. It would not be of the slightest value to do it, yet it is interesting to feel that the conditions are realisable. Suppose we had a turning table five yards in diameter, going around once in three or four seconds; and suppose here is a water trough around it, filled with water.

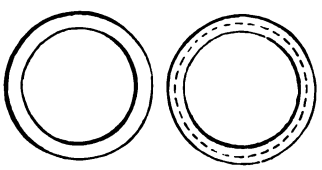
Stand up and look at this water in the trough; it is completely at a level with the motion of the table, but the outside is a little higher than the inside, in consequence of centrifugal force. Take that as the datum from which we measure all our constructions. Let one part of the canal be taken up by a pump. That is an arrangement for causing water to flow, and corresponds precisely to the voltaic battery. Cause water to flow around, and there will be disturbances and oscillations corresponding to the oscillations of the electric circuit before it settles down to the work imposed on it by the voltaic battery. Suppose, first, the water to be forced in the direction in which the table is turning. It will increase the effect of centrifugal force and cause the water to stand higher still on the outside than on the inside. Looking at the level or applying a test of levels, we have Mr. Hall's wire electrodes for testing the difference of potentials on the two sides of his strip. The pump is

Digitized by Google

stopped, the water settles again, and then water is pumped through in the opposite direction. It is now found that the level rises on the inside, and falls on the outside. Here is the fundamental dynamical analogue—I believe ultimate explanation, but I only venture to say analogue now—for Mr. Hall's phenomenon.

Now for Mr. Bidwell's ingenious last experiment, which is really very interesting as interpreted to us by Mr. Hall. Suppose we put in a barrier quite around here. That will give us two canals instead of one.

Everything remains the same until there is a current through the canals, and then we have the difference of potentials indicated by Mr. Hall. But make a hole in this barrier, which correspondends to the bridge across the slit of the metal strip. There will be a flow around the canal, and a continued flow through this little hole in the barrier. Suppose, for instance, the motion of the water to be in the same direction as the motion of the turning table. At a considerable distance from the place where the barrier has a hole in it we should have a higher level on the outside of the outer canal, a lower level on the inside ; a higher level on the outside of the inner canal, a lower level on the inside. That state of things would exist up nearly to the hole of the barrier. At the hole in



the barrier there will be a continued flow of water through, in virtue of the level being higher here and lower here than the average. That state of things exists a little distance on each side of the hole, and if the hole be small in comparison with the size of the canal, the result will be a point, P, near the hole on the inside, which, notwithstanding the hole is there, will share the higher level that exists all around the outside of the inner canal, and a point, Q, near the hole on the outside will share the lower level of the inside of the outer canal. Thus we have the complete hydraulic analogue, both for the fundamental phenomenon and for that curious illustration of it with which Mr. Bidwell attempts to disprove it.

Professor Silvanus Thompson : If I have any criticisms to make on what Hall has said, it will be directed to two points on which experiment can be further brought to bear. In the first place, when you had those two metal strips, clamped in the one case at the ends, in the other at the middle, I think you told us those strips were made of steel. Did you try any other metal than steel ?

Mr. Hall : I did not.

Professor Thompson : What was the size of the magnetic pole-piece that you applied in front and behind the strip ?

Mr. Hall : Perhaps 3·5 centimetres in diameter. The strips in which I used the clamp were entirely within the poles—about 3 centimetres long and 1 centimetre wide.

Professor Thompson : In my experiments I was very particular to employ very large pole pieces that very much more than covered the strips, and then again, pole-pieces which covered only portions of the strip, and I found the effects to be different in the two cases. If you have a strip with a current running through it and placed in a uniform magnetic field, it will not be bent up at the middle as compared with the edges. There will be no bending of this kind, because the whole strip will tend to lift uniformly. But, in the first place, if you are working with a pole-piece that considerably exceeds the size of your strip, you have not got the uniform field, and the mechanical sidewise thrust is greatest where the field is strongest. There will be a greater thrust at the ends than at the middle, which will have the same effect as if the strip were clamped at the middle, and you would have the same effect whether the strip were clamped at the ends or the middle.

Again, taking the size of strip shown us here, suppose you were to warm one edge 5° centigrade. There will be a slight depression toward the other side with those clamps, which would certainly admit of an increase of movement. Therefore I cannot accept those clamps as being sufficient to prevent the existence of the Bidwell effect.

My next point of criticism is as to the diagram which we had of the equipotential lines when Mr. Bidwell's alleged reversal of the effect was so well explained to us by Mr. Hall. You had the slit, and the bridge across it, and I followed every point except one ; I do not understand when you have a continuous metallic surface how you can have equipotential lines ending on the strip, here and there (indicating) ; it must somehow get across from this strip to that.

Again, I think that the fact that no Bidwell effect was observed by Mr. Hall in those steel strips may be due to the fact that they were of steel, and that with some more magnetic metal, such as gold or tinfoil, the Bidwell reversal might have been obtained.

Lastly, I have very carefully examined that on which the whole thing rests—the position of the equipotential lines. At the meeting of the British Association three years ago, when I took exception to certain points of Hall's explanation, I ventured to suggest, although I had not tried the experiment, that although one portion of the lines might be twisted out of the perpendicular, you did not have the lines, as a whole, twisted out of the perpendicular, and that it was an internal effect either of stress or change of electrical resistance. I had the equipotential lines something as I have drawn them here, and I remember, while I was talking, Sir William Thomson went to my diagram and crossed it out, saying, "No, no, here is how the equipotential lines must go."

With the most delicate galvanometer I could use I have carefully examined the equipotential lines. The strip of tinfoil which I took was 10 centimetres wide and 30 centimetres long, fastened with brass clamps at the two ends. When there was no magnetic field the equipotential lines ran beautifully straight across. But when we applied a magnetic force by pointed magnetic poles, placed in front and behind the strip, on making a careful exploration we found that a little before and behind the magnetised point those lines bowed out as if there had been an increase of electrical resistance in that part of the foil. We proved it afterwards by putting strips of foil in a magnetic field and measuring the increase of electrical resistance, which proved to be a little over 1 per cent. We never could find the right plotting of the magnetic lines ; we only found certain curvatures, which could be entirely explained by electrical resistance.

I would ask Mr. Hall whether he has found that these equipotential lines are twisted all along the magnetic field in the manner in which his theory supposes they are.

Mr. Hall : It was settled, once for all, that they did run in that direction ; they ran slantingly through the whole length of the strip. That was the question at issue between Professor Rowland and myself. It was the opinion of one of us that the lines would be bowed at the ends. I called in another gentleman to witness that particular experiment, and before I tried it I predicted what I thought would occur. These lines ran slanting the whole length of the strip, which was of gold.

I cannot say what effect you would have when you have a small pole acting over a large strip of metal. I would suppose, however, you would not get any particular effect at the edge ; it would simply be a rotary magnetic effect.

There is another point that I did not mention this morning. Suppose we have a certain magnetic force, m, and a certain strength of current, C. We get a certain rotational effect from that, due, as Mr. Bidwell says, to a strain produced by the action of the magnet upon the current, and that strain reacting upon the current in the way we have discussed. We can double that strain in various ways. One way is to make the magnetic force $= 2m$. The force being doubled, the strain should be doubled, and we should suppose that the effect would be twice as great. But suppose we double the strain by doubling the current, then the strain will not only be twice as great, but the current flowing through this strip will produce twice the reacting effect. In other words, doubling the current should produce four times as great an effect as before. I do not find it so. In whatever way I produce the strain, by increasing the current or the magnetic force, the rotational effect is simply proportional to the strain.

It is evident the effect could not be proportional to the strain if it were produced by a reaction of the strain upon the current, because it is impossible to conceive of a case in which a given strain would not produce a greater electrical disturbance on the equipotential points when there was a current two flowing through the strip than when there was a current one flowing through it. There is evidently an intimate relation between the properties of metals, as I have studied them, and their properties under certain electrical conditions.

Professor Ball : When Mr. Bidwell's suggested explanation, by tension, &c., was made, it appeared to me only in the light of a plausible and ingenious way of getting at the other explanation. I so expressed myself to Mr. Bidwell, and he invited me to come and see his experiments ; and there was one thing which struck me, and that is the necessity of his theory and the foundation of it, viz., that the order of the different metals, whether positive or negative, in connection with the Hall effect, is exactly the same as the order in which they lie in respect to their thermo-electric properties when under strain. I saw Mr. Bidwell's experiments, and there was not the slightest doubt about it that in every case the metal which showed a thermo-electric effect in one direction showed a Hall effect in the same direction. It may be that Mr. Hall's casual remark just before he sat down, that there is evidently a connection between the thermal effects and the Hall effect, is all we can say ; and I think the final result will be that the Hall effect and the thermo electric effect both depend upon some peculiar condition of the metal, and that the one is not directly dependent upon the other.

Mr. W. H. Preece : I merely want to call Mr. Hall's attention to one inquiry that Mr. Bidwell has made. The essential feature is this : Whether there is contraction and dilation of the molecules on each side of the plate ? If you replace your steel or gold plate by a thin sheet of mercury, then the molecules, having free play among themselves, ought to indicate the condition of compression or relaxation. Mr. Bidwell has done this, and you will find the moment you make your contact and the current flows, all the mercury flies off, excepting little currents which rotate about in the most beautiful manner, and give you a proof that there is certainly dilation of molecules in respect to Mr. Hall's process.—*Electrical World.*

PHYSICAL SOCIETY.—Dec. 13.

Professor Guthrie, President, in the chair.

The following communications were read :—"On the Effect of an Electrical Current on the Rate of Thining of a Liquid Film," by Professors A. W. Reinold, F.R.S., and A. W. Rücker, F.R.S., read by Professor Reinold. In 1877 the authors communicated to the Royal Society an account of some experiments upon the electrical resistance of liquid films. The results then obtained showed that there was some disturbing influence present, and the authors now find this to be the action of the current upon the film itself. The films experimented on were, as in the original experiments, cylindrical and vertical, formed upon two coaxial platinum rings which are the electrodes by which an electric current can enter and leave the film. The mode of formation of these films and the precautions necessary to keep them from gaining or losing moisture by condensation or evaporation have been already described before the Royal Society. [*Phil. Trans.*, 1881, Pt. II.]

Digitized by Google

When such a film just formed is left to itself, it shows a set of colours of different orders arranged in horizontal bands. As it thins under the action of gravity these bands gradually broaden out and descend, a black band soon appears at the top, which likewise extends downwards. If a current is now passed downwards through the film the motion of the colour bands is accelerated, showing that the effect of the current is to assist gravity in thinning the film; the black band, however, becomes in part or entirely white. This upon examination is found to be due to the following action: the film is not directly dependent upon the upper ring, but is attached to it by a comparatively thick mass of liquid. The action of the current is to transfer liquid in its own direction, thus, like gravity, thinning the film. The mass of liquid, however, on which the film hangs by this same action is forced down into the black portion, which consequently becomes white. If the current be passed upwards the reverse effects occur; the downward motion of the bands is retarded, or, with a strong current, reversed. The explanation is precisely the same as before; the liquid is transferred along the film in the direction of the positive current; it sometimes collects in the form of pendant drops attached to the upper ring; these increase in size, and stream down the sides of the film. Professor Reinold then formed a plane film between two horizontal wires. The film was illuminated by the lime light, and its image projected upon a screen. The motion of the bands of colour in the direction of the current produced by 50 Grove cells was clearly shown.

In a discussion which followed upon the transference of matter with the current, Professor Ayrton described some experiments recently made by Professor Perry and himself, which showed that certain metals were carried through mercury in the direction of the current.

Mr. Boys remarked upon the apparent inertia of the film; the current seemed to require time to develop its action, no motion of the colour-rings being visible for some seconds after making the current.

Dr. Stone exhibited a tuning-fork interruptor commutator. This is an instrument for reversing an electric current through a circuit a given number of times per second. From the free end of a spring kept vibrating in unison with an electrically maintained fork by an electro-magnet in the circuit of the fork acting upon an iron armature attached to the spring project two small aluminium plates, side by side, but insulated by ebonite from the spring and from each other. These are connected by fine wires which do not interfere with the vibration of the spring to screws upon the base of the instrument to which the poles of a battery are joined. The motion of each plate is arrested upwards and downwards by aluminium stops, so that there are four such stops arranged at the corner of a rectangle. They are connected in pairs, diagonally, and each pair is in communication with one end of the external circuit. Thus, when the spring is up, the current flows to the aluminium plates, and is transmitted through the circuit in one direction. When the spring is down it flows by the lower stops in the opposite direction. The electromotive force is thus reversed in the circuit twice as many times as the fork vibrates per second.

Mr. Lewis Wright exhibited his new oxy-hydrogen lantern microscope. Details of this instrument will shortly be published. Geological, medical, and biological specimens were exhibited upon the screen with great distinctness, the definition being singularly perfect under the highest powers.

COMPANIES' MEETINGS.

Anglo-American Brush Electric Light Company.

An extraordinary general meeting of the shareholders of this Company was held at the offices of the Company, 112, Belvedere-road, Lambeth, on Monday last, Mr. J. S. Sellon presiding.

The SECRETARY (Mr. E. Garcke), having read the notice convening the meeting,

The CHAIRMAN, having expressed his regret that the President of the Company was unable to be present at the meeting through a pressure of engagements in the North of Scotland, went on to say that the subject for the consideration of the shareholders was of so simple and straightforward a nature, and had been so thoroughly dealt with in the circulars which had been received by them, that he felt any lengthened remarks he might offer would unnecessarily take up their time. He therefore proposed to answer any questions it might please gentlemen to ask, rather than to go over ground which had already been fully explained. He would ask them to accept as a matter of course the fact that their Directors had very fully considered the bearing of the proposed amalgamation, or rather he should say absorption of the interests of the Great Western and Midland Companies. And he would also ask them to accept as a matter of trust the policy which they had laid down. The time which had elapsed since the formation of these sub-companies had been sufficient to prove that, to a greater or less extent, the expectations which had led up to their existence had not been fulfilled. Many things had combined against that—amongst others the slow recognition on the part of the public of the value and advantages of the electric light; the disastrous attempts at legislation, which had without doubt up to the present time throttled a great and scientific industry, and which had almost taken the heart out of those, or some of those, who had earnestly engaged in the great work; and, in some measure, no doubt, the speculative spirit which at one time pervaded the community, and which brought about a natural reaction. All these elements combined had been against the success of the electric light; and so, too, as must be the case with every new scientific development, few persons at the commencement were sufficiently acquainted with the difficulties that beset it; and, altogether, a business which, under good management, could not fail eventually to be a success had been kept back by these obstacles. It was very easy to moralise on the past, but they had to look forward to the future, and in the future there was, he thought, very great hopes of the success which at one time was desired. With regard to the amalgamation it was considered by the Directors that concentration of energy and uniformity of plan and management were essential parts of such an organised system of work throughout the country as they desired to bring about, and in order to be able to carry out their policy it was necessary that they should have free hands throughout the country, and be untrammelled by reports which were friendly or otherwise, and which seriously interfered with their independent action. He would now only detain them by briefly summarising the effect of the proposed step as far as capital account was concerned, if it should meet with their sanction. And he might mention incidentally that if he were to judge from the very large number of proxies they had received the course they recommended appeared to meet with unanimous approval, for they had nearly 30,000 proxies. As explained in the statement before the meeting, the total number of shares which it was proposed to issue to the two Companies amounted to the value of £33,475. For this they received plant, installations, land, buildings, and stock, fairly estimated as being worth to the Company about £16,750; cash, about £7,700; unpaid calls to collect, £4,100—leaving a deficit, as against the nominal share issue, of £5,000, against which they received back the licenses and secured the goodwill of the 23 counties at present out of their control. He could assure them that the very careful consideration of the Directors had been given to these provisional settlements. He would also like to pay a tribute to the care and business-like treatment which had been paid to the negotiations by the Directors of the Great Western and Midland Companies. The Board could confidently recommend the acceptance of the agreements as now offered; and, if it were the pleasure of the shareholders that they should be accepted, the Directors had no doubt that the ultimate result would be one of satisfaction to them as well as to the shareholders of the two sub-companies whom they would then have to welcome amongst themselves. He commended to their judgment, and he hoped to their approval, the resolution which had been read by the Secretary, and which he would now formally move:—"That the Provisional Agreements entered into between the Corporation and the Great Western Electric Light and Power Company (Limited), and the Brush Midland Electric Light and Power Company (Limited and Reduced), dated respectively 28th November, 1884, and 29th November, 1884, and submitted to the meeting, be and the same are hereby sanctioned, adopted, and confirmed, and that the Directors be authorised to carry the same into effect respectively, with or without modifications, and for that purpose to enter into and execute all necessary deeds and documents, and to issue not exceeding 6,695 fully paid £5 shares in the capital of the Corporation, such shares to be numbered from 40,701."

Mr. GIBBS seconded the motion.

Mr. MEYER wished to know why this meeting should have been called for the 22nd December, when, in the ordinary course of affairs, in two or three weeks' time, the shareholders would have been informed by the annual report and accounts of the state of their affairs, and been better able to judge as to whether or not the purchase was likely to be advantageous for the Company. He wanted to know also upon what footing the purchase-money had been calculated, and went on to show that, according to the quotations on the Stock Exchange of the shares of the various companies, the purchase-money was not founded upon the relative value of those shares in the market, especially at the time when negotiations were commenced with a view to bringing about the proposed amalgamation. He could not help thinking that the result of the scheme now projected had been to raise the price of the Great Western and Midland Company's property not quite on its merits, and questioned whether the Corporation were not having the worst of the bargain. He suggested to the meeting whether it would not, under these circumstances, and in the absence of the annual report and accounts, be better to adjourn the meeting until the latter should be placed in the hands of the shareholders.

The CHAIRMAN, in reply, said that the Directors of the Company entirely ignored the Stock Exchange or any of the prices that might be quoted there with regard to one Company or another. That had nothing at all to do with the conclusion they had endeavoured to arrive at, namely, a satisfactory arrangement with those two Companies, in order, as he had said, to carry out the policy which they had laid down. It was very possible that some weeks or months ago shares might have been bought in both the Great Western and Midland Companies at a very much less figure than the value arrived at in the course of their negotiations. Calculations upon Stock Exchange rates were not to be relied upon in cases of that kind, because those rates were continually fluctuating. The Board had followed one course. They had endeavoured to arrive at the assets of those Companies as they stood, and they had ascertained to the best of their judgment the value which the absorption of the Great Western and Midland Companies could be estimated at in enabling the Board to carry out their intended policy. As he had stated in his former remarks, the expectations that had been formed of those sub-companies had not been fulfilled, which accounted probably for the low price to which the shares had dwindled. But the moment there was a value given to anything in the world of course its importance increased, and they had been obliged, therefore, to deal with the companies in question upon what he said was a fair and equitable basis. He was quite sure that those who could examine the accounts as the Board had done would be quite satisfied with the result that they had arrived at. The absolute summary of the scheme would be this: that the Brush Company would receive in cash about £7,700, and the calls due to the Midland Company, which were £4,100, and they had good reason to suppose that the bulk of that money would come in; and if it did not come in, of course there would be no issue of shares to the extent of the amount unpaid. Therefore the Com-

Digitized by Google

pany was quite protected so far as that was concerned. The way in which the value of the plant, installations, land, and buildings was arrived at was a very satisfactory one for this Company, because it had been taken upon what no premium had been paid. As he had explained, however, there was a deficit of £5,000—that was to say, they had to issue about £5,000 more of fully paid shares for the goodwill and the return of the concession for the twenty-eight counties already referred to. He did not think that that sum could be grudged. He thought that the shareholders of the companies to be absorbed might perhaps say that it was the minimum value which was given. At any rate, it was one which commended itself to the judgment of the Directors, whom the shareholders must either trust or mistrust. If they trusted the Board the latter would be very glad to work for the Company, but if they mistrusted the Directors they would be very glad to let the work fall into other hands. As to the calling of the meeting, at present he could only say that it was extremely desirable to close all these questions, so that there would be no complication in the accounts and report to be submitted to the annual meeting. It would, they thought, be a pity to bring in any complication at the general meeting which would operate prejudicially against the working of the Company. He would therefore ask Mr. Meyer to withdraw his suggestion for adjourning the meeting.

A SHAREHOLDER pointed out that the Stock Exchange quotations were the only barometer by which the value of the different companies' shares could be ganged.

The CHAIRMAN said it was an exceedingly dangerous and untrustw rthy barometer to go by.

After a few more remarks from Mr. Meyer and the Chairman bearing on the adjournment of the meeting, the former gentleman did not press his amendment, and the resolution was put to the meeting and declared carried, which concluded the business.

The Provincial Brush Electric Light and Power Company (Limited and Reduced).

The second ordinary general meeting of the shareholders of this Company was held at the Company's offices, 68A, Cow Cross-street, E.C., on Monday last, under the presidency of Mr. Thomas Fry.

The SECRETARY (Mr. Alfred Jermyn) having read the notice convening the meeting,

The CHAIRMAN said the Directors had asked the shareholders to meet on that occasion at the factory because they wished them to see how the business of the Company was being conducted under the altered conditions referred to in the report. Something had been said about the date fixed for the meeting, but the explanation was this: It was only on Saturday that the sanction of the High Court of Justice was obtained for the reduction of capital in the Company. And as regarded the place of meeting, he thought it was most desirable that the shareholders should realise the full significance of the change that had taken place in the Company's position, and to see of what importance it was to them that they had a large interest in a manufacturing company for whose accumulators and other patented inventions there was a growing demand. He need not tell the meeting that nearly all the electric lighting companies had lately fallen on very bad times. It was thought when this Company was started, with other kindred undertakings, that to obtain a concession from the Brush Company, no matter at what cost, was all that was required to lay the foundation of a profitable business. Then came the Electric Lighting Act of 1882, and it was believed if they could only secure provisional orders success was certain. Well, he need not tell them all those hopes and expectations were soon rudely shattered. They saw the Scotch Brush Company retire early from the field. Then came the collapse of the Metropolitan Company, which brought disaster on the shareholders, and also affected prejudicially the interests of all other companies. They now heard that the Great Western and the Midland Companies, not desiring any longer to walk alone, had resolved to return to the parent nest. No doubt those companies could only work under the licences that had been granted to them by the Brush Company. But the position of the Provincial Brush Company must be considered to be entirely different. They were doing business independently of the Brush Company, and were, through their association with the Consolidated Company, in possession of a system which they thought would be adopted very generally for electric lighting. Let them glance for a moment at the position of the large companies—the Brush, the Edison-Gower, the Storage, and the Maxim-Weston—and they found disclosed in the published accounts of these companies that they had all met with enormous losses in doing unprofitable work, and in addition to that they had been compelled to make immense reductions of capital upon a revelation of their assets. Looking at that state of things the shareholders might congratulate themselves on their own position. Although they had met with certain losses their position was in the main satisfacrory, because after making those losses they had now laid the foundation of a profitable business. He would refer them to the working of a system by the South Eastern Company at Colchester, because they had a like interest with the South Eastern in the adoption of the system in other places. They claimed that at Colchester an undoubted scientific and mechanical success had been achieved, and he believed that it would be followed in due time by a commercial success. Of course all the companies had been established with a view to the making of money, and it was to that object that they must direct their attention. They thought they had got over many of the preliminary difficulties, and they were now obtaining from day to day an accession of business that would be greatly to the Company's advantage. Not only did they regard the success at Colchester as a fact establishing the working of their system, but the public notice of what they had done there, or what had been by the South Eastern Company, had brought to the Company a very large amount of business. And it had come to them without solicitation from all parts of the world, amongst others from Portugal and Spain, and in the way of actual business and inquiries from India, Canada, New Zealand, Russia, Sweden, and Italy; and therefore the Board considered that, with their present working arrangements with the South Eastern Company, and with the interest they had in the Consolidated Manufacturing Company, a certain amount of business was sure to follow. As to Lisbon, the estimate given by the South Eastern Company for the installation there amounted to £32,000. A preliminary order had been received and executed to the extent of over £1,000, and so certain was the business that they found that money was lodged in the bank here which the Company drew against the shipment of their plant. This Company, he might tell the meeting, had an interest in the execution of these orders, as they were accepted on joint account, because they were both interested in the Consolidated Company, and contributed like funds to the support of that Company. They considered that, having reached this point, having since the 30th of June, when the accounts were made up, obtained the orders to which he had referred, they had now a fair prospect of doing profitable work, and they were doing it at a comparatively small cost. They knew that outside the Board an approach had been made to the Brush Company, with a view to come to some arrangement with them similar to that carried out by the Midland and Great Western Companies; but at present he could not say that there was any basis for such an agreement. The Brush Company, it was said, were ready to take over on certain terms the whole of their assets, but would that Company take over their liabilities—liabilities which had been accepted in connection with the Consolidated Company, and which they were bound, he thought, to meet? He doubted very much, if they approached the Brush Company, whether they would find that there was any basis upon which they could treat. That being so, or even supposing there was any chance of agreeing to terms, it led him to say that they could much better stand alone and continue to do their own work. In this Company there was no immediate necessity for making a call, and he might say that whenever calls were made they would be made to a very moderate extent, not exceeding 2s. 6d. a share at each time. In conclusion, he thought they had reached that point when the Directors might very fairly ask the shareholders to support them in their endeavours to carry to a successful end the business of the Company; and he therefore, with great confidence, moved the adoption of the report and accounts.

Mr. CHAS. WAPSHARE seconded the motion, and gave an account of the present position of the Consolidated Company. The shareholders, he said, would remember that at the last June meeting it had been explained that the factory would be probably too small for carrying on their operations. The Board had accordingly increased it by taking a lease of the adjoining premises, and they were now in a position to do a large amount of business, and he was glad to say that there were indications of very extensive orders coming in, out of which the Provincial Company would reap a certain benefit, as they did business constantly with the South Eastern in supplying dynamos, secondary batteries, and other plant, on which they got a large discount of 20 per cent. His principal object in addressing the meeting as to the Consolidated Company was to point out the value of the property. In doing so he wished to say that he attached the greatest importance to their secondary battery. If he was correct in the view he took—and he did not wish to be enthusiastic, because no one engaged in the electrical industry should indulge in enthusiasm to any great extent—he had no hesitation in saying that there would be most profitable returns from the sale of their secondary batteries. Having briefly recounted the merits of the battery in question, the speaker went on to say that there were daily increasing signs of the growing demand for the electric light, and the concensus of opinion went to show that it was only by storage that success could be attained. That had been the opinion of the Board all along, as the shareholders were aware, and they had never swerved from it. And had it not been for the depression of trade, and a variety of other causes which he would not dwell upon now, it would have been impossible to keep pace with the demand. Estimates were being constantly asked for, and everything seemed to go to establish the fact that the taste for electric lighting was developing, and the Company had a most promising prospect before them. The electric lighting industry was entirely new, and they must not be judged in the first two years' working, under exceptional difficulties. The Board had never been free from anxiety since they had been connected with the business, and they had spared themselves no trouble to make it a success, giving the most minute attention to all the complicated questions that had arisen from time to time. Fresh difficulties might still arise, but he had no doubt that they, too, would be overcome. Up to the 31st December, 1883, there were 78 electric light companies registered, and he believed he was correct in saying that at the present moment there were not ten that were capable of undertaking any real or useful work. The rest were moribund, or deceased. As regarded Colchester, which was the keystone to the position, he might say that doubts had been raised as to whether the B K T system was a success. He visited that town at the end of last week to see what was really the case, and he found the lights burning brilliantly, and the consumers all expressed their satisfaction with the light.

Mr. R. BRAITHWAITE moved an amendment, the effect of which was to defer the adoption of the report and accounts, to adjourning the meeting for a month, and to appoint a committee of two gentlemen to inquire into and report upon the present position of the Company.

Mr. CUMBERBACH seconded the amendment, which on being put to the meeting was declared lost.

Mr. BRAITHWAITE thereupon demanded a poll, and Mr. Burt was afterwards appointed scrutineer.

Digitized by Google

A short and unimportant discussion followed, and the original motion was put and declared carried.

On the motion of Mr. F. G. BEST, seconded by Mr. HYDE, both the retiring Directors (Mr. R. Cunningham and Mr. Thomas Fry) were re-elected, as were also the auditors, Messrs. Price, Waterhouse, and Co., and the proceedings terminated.

Great Western Electric Light and Power Company.

An extraordinary general meeting of the shareholders in this Company was held at the offices, Great Winchester-street, E.C., on the 23rd inst., under the presidency of Mr. J. Braithwaite, jun., when the resolutions passed at the meeting on the 8th inst., confirming a provisional agreement between the Anglo-American Brush Electric Light Corporation and the Company for the amalgamation of the Companies were confirmed, on the motion of the Chairman, seconded by Mr. Stewart.

The Oriental Telephone Company (Limited).

An extraordinary general meeting of this Company was held at the City Terminus Hotel, Cannon-street, on the 22nd inst., under the presidency of Colonel Gouraud, in pursuance of a requisition to consider two resolutions appointing a committee of investigation and increasing the number of Directors.

The CHAIRMAN said that the Secretary would read the notice convening the meeting, immediately after which he proposed that the gentlemen in whose interests the meeting had been called should take precedence, and move the resolutions of which notice had been given. He took that perhaps somewhat unusual course in view of what he had been told, namely, that it very often happened that some time and a great deal of temper were frequently wasted in order to get this concession.

The SECRETARY (Mr. W. G. Hall) having read the notice convening the meeting,

The CHAIRMAN said it was now in order to move the resolutions.

Mr. THOMAS LLOYD stated that in the circular he had sent out to the shareholders he had briefly pointed out the chief reasons which had induced his friends and himself to act in this movement. They would remember some little time ago that a committee of investigation was appointed by the shareholders of the Consolidated Telephone Construction and Maintenance Company, and that committee reported very unfavourably about three of the four Directors.

The CHAIRMAN (interposing) said that if Mr. Lloyd was going into the report of the committee of the Consolidated Company, it would be a great deal better if the whole of the report were read.

Mr. LLOYD stated that he had no intention of dealing at length with that report, but only wished to remark to the meeting why it was that those with whom he was acting had taken the place which they had taken, and the first thing that induced them to do so was the report of the committee bringing charges of a breach of trust against certain members of the Directorate of the Consolidated Company who were also Directors of the Oriental Company—three out of the four Directors of the Oriental Company who were permanently resident in London. It had seemed to them reasonable and proper that they should inquire whether the affairs of the Oriental Company were being better managed than were the affairs of the Consolidated Company—according to the report of the committee, the correctness of which it would be understood he was not assuming. It had, however, been accepted by the Consolidated shareholders, and in consequence the members of the investigating committee were now in the places of the old Directors of the Consolidated Board. No charges, therefore, which had been brought by that committee had been accepted by the shareholders of the Consolidated Company, and it had seemed to them reasonable and proper that they should inquire whether the affairs of the Oriental Company were being better managed. They trusted that they were. He should think that the Directors against whom such very grave charges had been brought ought to welcome the proposal for investigation if everything was straight. The requisitionists had no interests adverse to the Board, and they were not in the least anxious to find them guilty in any way. In the circular which the Directors had sent out to the shareholders, they said that they had invited the shareholders of the Company individually to come to the office and make any inquiry they pleased. His (the speaker's) first answer to them, however, was that at the last meeting of the Company a consultative committee was formed consisting of three members—Mr. Pender, their late chairman; Mr. Akers, the largest shareholders in the Company; and Mr. Grewing. The majority of that committee, Messrs. Akers and Grewing, were soon convinced that a consultative committee was a farce, and that it was intended to be a farce, and that any unauthorised inquiry would do no good. Therefore Mr. Akers and Mr. Grewing were assisting the present movement of which he (the speaker) had made himself the exponent. Mr. Akers held 24,000 shares, and that being so, he thought they would agree with him that that gentleman was not likely to do anything to injure the Company. He considered that when Mr. Akers and Mr. Grewing thought that there should be a committee of inquiry that was strong *primâ facie* evidence that a committee of investigation ought to be appointed. He wished now to call attention to the report of the auditors, which the Directors had sent out with their second circular, and if they had carefully read that report they could not have failed to be struck with the extreme caution which the auditors had displayed. They were careful not to make themselves responsible for anything by the qualifications which they had made. The shareholders also saw that the auditors were very careful to avoid telling them how the paid-up capital had been spent. In the circular which he (the speaker) had sent out he stated that the paid up capital had been spent, and that in addition the Directors had borrowed a certain sum of money, which they themselves now told the shareholders amounted to £3,500. Therefore the statement which he had made, that the capital had gone, was verified, and beyond that there was a sum borrowed. The whole of the paid up capital was £110,000, of which £40,000 was paid to the vendors, leaving £70,000 to be accounted for. Although in his circular he had purposely directed the attention of the Directors to the point, and challenged them to afford an explanation of the matter, the Directors and the auditors had carefully refrained from saying a word as to how that £70,000 had been spent. In addition to that there was the sum borrowed from the bankers of £3,500 to be accounted for. They had a right to make an investigation into this point. The shareholders would remember that when the Company was brought out great stress was laid on the fact that India offered a very profitable field for telephonic enterprise, and personally he believed that that was so. One would naturally have expected that the Directors would have worked that specially profitable field, but instead of doing so they found that the Board had established two subsidiary companies, one in Bengal and the other in Bombay, and so far as he could trace and so far as the auditors' report went, the Directors had handed over the rights of the Company in Bombay and Bengal without receiving anything for them. He would be pleased if he was wrong, but he confessed he had looked very carefully into the matter. He thought that as to this question they had a right to an investigation by an impartial and independent tribunal. If the Company had got anything for the concession of their rights in Bengal and Bombay it was a further reason to inquire what had become of the proceeds, in addition to the £73,000 already mentioned. Not only had the Directors made over the rights of the Company in Bombay and Bengal, but they had paid the subsidiary companies to take those rights away from them. Estimating the value of the rupee at two shillings, the shareholders would see that the preference shares of the Bombay and Bengal Company amounted to about £98,000, upon which the Directors had given a guarantee for five years of no less than 8 per per cent., involving a charge of over £6,000 a year. He found that the Directors still held about £26,000 of those shares, but that they had parted with £72,000 of shares. What was given for them, how were they induced to guarantee 8 per cent. upon them, and what was the reason for so large an amount being paid? All these he thought were questions that ought to be answered by a committee of impartial shareholders. He had throughout refrained carefully from making imputations against the Directors, but in the circular issued by the Directors they saw that imputations were cast upon this movement of the requisitionists. He admitted that they had thrown an imputation on the Directors if it was to be contended that the proprietors were not justified in inquiring into the affairs of their own property. But he never heard that proprietors had not a right to inquire into their own affairs. He concluded by moving the first resolution.

Mr. ADDISON seconded the motion, and said he wished first of all to call attention to the third paragraph in the Directors' circular, in which they stated "the Board had no hesitation in boldly impeaching the worthiness of the motives of the real instigators of this agitation." Now, he thought that that statement was very unfair. The agitation, if they pleased to call it so, arose in this way. He received a letter from Mr. M'Nab in Scotland, who was the holder of about 1,000 shares, and he wrote to him as a resident in London, asking him to see if he could not find out anything about the Company, with the management of which Mr. M'Nab was dissatisfied. About this time he (the speaker) received the committee's report on the affairs of the Consolidated Company, of which he was a large shareholder. Upon reading that the impression that came to him was the same which occurred to Mr. Lloyd on the receipt of Mr. M'Nab's letter. He remembered that Mr. Akers some time previously had asked him to join a committee with a similar object to what was now proposed. But he found out that it was simply to join Mr. Pender on the committee of consultation which was appointed at the last meeting. Therefore he did not consent to what Mr. Akers proposed, because he (the speaker) knew nothing of what occurred at the last meeting of the Company, although he supposed that something unsatisfactory was said, or no committee at all would have been proposed. The appointment of the consultative committee at the last meeting was, however, a perfect farce, and they therefore proposed now the appointment of an independent one at this meeting Mr. Lloyd had said that they had no charges to make, but they thought that as the Directors were mostly promoters and late Directors of the Consolidated Company that they ought not to remain silent after what was said in the report of the committee which had examined into the affairs of the Consolidated Company. They would see from the list of the Directors of the Oriental Company that Mr. Edison and Mr. Hubbard resided in New York, and Sir William Thomson in Edinburgh. There therefore remained only Colonel Gouraud, Mr. Carnegy, Mr. Bigelow, and Mr. James Pender, and he believed that Mr. Carnegy was away now until next June, so that it practically came to this, that there were two Directors of the Consolidated Company on the Board against one other Director, or, with Mr. Carnegy, there were three Directors of the Consolidated Company against this one other Director. In the report of the committte on the Consolidated Company's affairs they would see that the Oriental Telephone Company was mentioned several times with respect to the different transactions in connection with that Company, and he thought that that rendered it still more necessary to see what those contracts were. He knew from what took place at other meetings a great objection was taken to having committees of investigation. In many cases such appointment might be objected to; but what they had seen attending the inquiries which had been made by the two committees of the Consolidated and the Gülcher Companies proved that such committees were not always to be objected to. Most of the Directors of the Oriental Company to which they were referring had their holdings in the Company in fully paid-up shares, and consequently their interests were antagonistic

Digitized by Google

to those of the general body of the shareholders, because it did not matter to those Directors if the rest of the money which had to be called up on the shares was called up. Mr. Lloyd had already referred to the auditor's report, and he (the speaker) did not think that much was to be got out of the report in the way of information by the shareholders, seeing that everything in it was qualified. Mr. Edison, who was the promoter of the Company, had given his proxies to the requisitionists to the extent of about 16,000 shares, a fact which showed that other people besides the requisitionists thought that something ought to be done. The present Directors and promoters had been on the Board and had had the management of the Company since the 14th of February, 1881—nearly four years—and he thought it was time that a change should be made. The Directors had talked of resignation, a proceeding which he regarded as very unfair. For why should they try and intimidate the shareholders by such a threat if the requisitionists carried their point? He concluded by seconding the motion.

The CHAIRMAN, on rising to address the meeting, was asked to put the resolution, to which he replied that the resolution had not been sent up.

Mr. LLOYD requested that the Secretary might read the resolution which had been sent in with the requisition.

The CHAIRMAN said that no resolution had been sent in with the requisition.

The SECRETARY preceeded to read the requisition, stating that the first object was, "To consider the propriety of appointing, and, if thought desirable, to appoint a committee of investigation, to examine into the affairs of the Company, with power to inquire into and report upon all agreements effected with subsidiary and other companies."

Mr. LLOYD said that he would move that a committee be appointed for the purpose stated.

The CHAIRMAN said that he understood that the resolution was as follows (and Mr. Lloyd would correct him if he was wrong, as he wanted the exact language to be given):—"That a committee of investigation, consisting of five shareholders of the Company, be appointed for the purpose of examining into the affairs of the Company, with power to inquire into and report upon all agreements effected with subsidiary and other companies." He asked Mr. Lloyd if that was the resolution?

Mr. LLOYD having answered in the affirmative,

The CHAIRMAN continuing, said that the first thing he wished to refer to was a statement of Mr. Lloyd, which certainly had gone very far beyond anything which that gentleman had stated in his circular. Mr. Lloyd had stated that the members of the Oriental Board who were Directors of the Consolidated Company had retired from the Board of that Company because the report of the committee of investigation of the Consolidated Company had charged them with breach of trust. Mr. Lloyd had said nothing so specific as that in his circular, and he wished to say that Mr. Lloyd's statement here had given him (the Chairman) a very important clue to information which he had desired, because in one of the weekly papers (one of many which had commented somewhat freely in connection with the affairs of the Consolidated Company and of this Company) that precise charge in the exact language of Mr. Lloyd had been made. It was so absolutely untrue that there was any such change in either the first or the second report of that committee that it seemed inconceivable that any one, however careless a reporter or editor of a newspaper might be, could have based such a statement on either of those reports. He had received a legal opinion which he had asked for to the effect that there was not the slightest foundation in either the first or second report of the committee for the statement made in the newspaper referred to, which Mr. Lloyd had now repeated—that was that none of the gentlemen named were charged with breach of trust, and, as the newspaper put it, "other dereliction of duty." He had been informed that it was Mr. Lloyd who wrote the article in question. They were further advised that it was undoubtedly libellous, and that the author and utterer of it ought be well punished, and they proposed to take further action in this matter. He had it on the very best authority that Mr. Lloyd, who had posed so prominently and so feelingly in the matter, had been employed for the purpose of the work he had in hand. He had said that the report of the committee of the Consolidated Company was the first cause (and Mr. Addison had corroborated that statement) of this agitation for a committee of inquiry into the affairs of the Oriental Company. He could not let that statement pass, because it was not true. As a matter of fact it so happened that before the report of the committee was issued, and therefore before any question arose in connection with that report, he received a communication from a gentleman whom he did not know, and did not now know, which was briefly to this effect—that there was going to be a devil of a row in the Consolidated Company, and that a serious attack was going to be made on the Directors of the Oriental Company who were Directors of the Consolidated Company, and the purport of the communication was that the Directors had better get out. That was the plain language of it, but it was to be a little more quarrel at the finish, and words to the effect that if they did not get out they would be kicked out. That they were —— Yankees in control of the Company, and that English people had lost enough of money in American railways, and were not going to have companies managed in London by Yankees. He thought it was a good deal to put on the shoulders of any gentleman the losses which had been made by investing in American railways. This information was repeated to him more than once with a view to their retiring to avoid a row. The matter was considered by them. He wished to say, and it would be in the minds of many of them, that he had been Chairman of this Company something less than nine months, and he was very reluctant to accept the chairmanship, and did so at great inconvenience. Ever since he had been in the chair it had been his desire to be relieved from it; but to be told what he had mentioned to them was the very course of all courses likely to make any man sacrifice his personal convenience, and see the thing out in a manly way. So much had been said about the report of the committee of the Consolidated Company that he particularly wished to say these few words on the subject. Mr. Lloyd had stated in a private letter which he had circulated before his printed statement, that the three Directors of the Consolidated Company who were Directors of this Company were gravely compromised, and that in the second report of the committee they were condemned still more, and Mr. Lloyd also said that he (the speaker) and Mr. Cargill had resigned their position on the Board of the Consolidated Company in consequence of that report. Now those reports—both the first and second—of the committee contained no charge whatever against either of the gentlemen who were Directors of this Company at that time, and he challenged any contradiction of that statement.

Mr. LLOYD, interposing, said he contradicted that statement most emphatically.

The CHAIRMAN observed that probably the meeting would not take any statement on this point in settlement of the question, but he repeated that he challenged the accuracy of the statement which Mr. Lloyd had made. There were, it was true, insinuations without number in the reports of the committee against the Directors of the Company, and more or less against the other ten directors who constituted the Board of the Consolidated Company, numbering fifteen from first to last. There was no denying this, but insinuations could scarcely be answered. His resignation from the Board of the Consolidated Company was not in consequence of the report of the committee. He had before him the proceedings of the ordinary meeting of that Company, at which he gave notice of the circumstances under which he had joined the Company originally (to which he again alluded). He remained in the Consolidated Company until it was out of its difficulties, and the gentlemen who were now Directors of the Consolidated Company were enjoying the fruits of the labour of the former Directors [laughter]. He made that statement deliberately. He (the chairman) seconded the appointment of the committee of the Consolidated Company, and he was glad to have a committee of investigation there. Mr. Cargill did resign in consequence of the report of the committee, to this extent that some one at the meeting said he wished that Mr. Cargill would resign, and some others not wishing to remain did resign, and he resigned immediately, and the resignation both of himself and of some others from the other companies referred to was in consequence of their resignation from the Consolidated Company, as they held their positions in those other companies consequent on the position they held in the Consolidated Company. Mr. Lloyd said he wished to know where the £70,000 had gone, but the various annual reports of the Company had shown where it had gone. He had said that the Company had got nothing from the Bombay and Calcutta companies. He (the speaker) could not conceive a more reckless statement. They got from those companies £34,000, in cash for the £25,000 which they had spent in establishing their businesses up to a certain time, and in addition £19,000 of the guaranteed shares, about which so much had been said. The effect of this transaction was that the Oriental Company got back all they had spent, a large amount in addition, a very large interest in the companies—about two-fifths—and they secured further working capital for the development of the business in those places—working capital subscribed by local people, and to a very large extent by natives. But for this they would, he was informed, have had to leave their money in those businesses, and they would have had to put in the further money which the local people put in, and they would not have had the local support, which was very important in enterprises of this kind. It was very important that such misstatements as those which Mr. Lloyd had made should be corrected He wished also to point out that in the case of Bombay the sale was made by the shareholders. The Board of the Company was then a much larger Board. They called the shareholders together, explained the matter at great length to the shareholders (and Mr. Akers was present, and asked a great many questions), and the matter was unanimously confirmed. In the case of the Calcutta Company the same course was taken, with this difference—that at the confirmation of the sale to the Bombay Company the shareholders gave power to the Directors to do similar business in the future upon their own authority without troubling the shareholders to meet to confirm it. It was almost immediately following the transaction in connection with the Bombay Company that the Calcutta Company was formed, and substantially upon the same lines, with the exception that the public did not come forward so freely as they had done in the case of the Bombay Company, with the result that the Oriental Company had to take a larger interest in the Calcutta Company. Mr. Lloyd had said that the guarantee they had given came to more than £6,000 a year, but the amount of the guarantee was decreased to the extent of the shares held by the Oriental Company. In the case of the Calcutta Company, moreover, there was a provision for a reserve fund of 1¼ per cent., upon which the amount paid to the vendors (that was paid to this Company), had to be invested every year, and which in the course of five years over which the guarantee extended would amount to a very large sum, which the "A and B" shares held by the Oriental Company would participate in. The outside possible losses in fact that could accrue to this Company in the event of the two Indian Companies earning nothing on account of the guarantee until its termination would be about £4,000 a year only.

A SHAREHOLDER asked what the amount of the sinking fund came to.

The CHAIRMAN: £791 a year. This was a reserve fund put aside by the Calcutta Company, and invested in Government paper. Mr. Hall informed him that this charge was part of the working expenses. He contended that the policy which had been pursued in connection with the two Indian companies had been a wise one, and he ventured to say that it was not reasonable to be expected that during the five years over which the Oriental Company's guarantee was to run the Indian Companies would earn nothing, and their receipts were increasing and their expenses diminishing. The shareholders knew that one of the great causes of the slow progress made by the telephone in this country had been the policy of

Digitized by Google

the Post Office, and the Directors had it on the best authority that the policy here had been dictated to the authorities in India. Upon the change of policy in England the Directors took the necessary steps to bring about a change in India, and he thought he might say that they had an official assurance that the Indian authorities would be recommended to follow the change which had taken place here. That would have a very important bearing upon the future. As to another of Mr. Lloyd's remarks, none of the Directors of this Company had in any sense been promoters of the Consolidated Company. Allusion had been made to the frequency with which the name of the Oriental Company had been dragged into the report of the committee on the affairs of the Consolidated Company, and that report had referred more particularly to what was known as the 4,000 telephone transaction. He wished to say on that point that the contract for the 4,000 telephone contract in question had absolutely nothing whatever to do with the Oriental Company, and it was impossible to conceive how it ever could have. He would only make one other reference to that contract. The transaction was one that concerned a great many people, nearly all of whom, if not all, were gentlemen above reproach. It was a most complicated transaction, which at its beginning certainly gave no indication of its ending. When he told them that it was a year and a half before that transaction could be settled, notwithstanding that it was in the hands of four of the most eminent firms of solicitors in London, they might form some faint conception of what a difficult transaction it was. As far as he was concerned, he had nothing to regret in his connection with the transaction, and he might add that the three gentlemen whose names had been mentioned in connection with it—Messrs. Bigelow, Cargill, and himself—acted as attorney for some twenty-five different people. That accounted for their names in particular having been associated with it. The gentleman who had seconded the resolution had spoken with very telling effect about the proxies of Mr. Edison having been given to the requisitionists. But the shareholders ought to have begun by saying that after the first circular which the Directors had sent to the shareholders they had determined to call the shareholders together themselves, and they had called a Board meeting for the purpose. But, by a very singular coincidence, that morning, just as they were about proceeding with the business of calling an extraordinary meeting, they received the requisition. But at that time, in anticipation of the meeting which they intended to call, not only the Edison proxies but others which the seconder might have mentioned, which the requisitionists thought they had the support of, were in the hands of the Directors. Reverting to the question of Mr. Edison's proxy, the Chairman said that he had a letter from that gentleman, telling him that Mr. Johnson and Mr. Batchelor, his co-partners in the Edison Company, had sold their shares, and that in doing so they had been obliged to give a power of attorney as to voting on those shares. I——

Mr. OPPENHEIM (interposing) was understood to say, as to the purchase of Mr. Edison's shares, that the remarks of the Chairman were untrue. The speaker afterwards alluded to the part which he had taken in the movement, and to his having backed up Mr. Lloyd, as he had promised, through thick and thin. He had nothing to say against Colonel Gouraud personally, and he was sorry to come into collision with gentlemen who, he was ready to admit, managed the Company according to the best of their lights. That was no reason, however, why the shareholders should not endeavour to get things better managed.

The CHAIRMAN said that the meeting would understand that Mr. Oppenheim had denied having purchased the shares, but he (the Chairman) had not said that Mr. Oppenheim had purchased them. He now wished to give them a few figures as to the progress of the Company. Last year the number of subscribers to the subsidiary companies and to the exchanges worked by this Company was 1,183. Thus, up to the latest dates published, averaging about ten months in the year, the number was 1,532, being an increase of nearly 29 per cent.; and, if the same progress continued for the year, the increase would be 34 per cent. The revenue at the end of the year was £19,800, and for about ten months of this year it had been about £22,600, being an increase of about 14 per cent; and, if this same progress continued for the whole year, the percentage of increase would be nearly 17. The only centre which was really doing very badly was that in Hong Kong, and they had closed that rather than continue to lose money there. Concurrently with the progress he had mentioned, there had been a reduction in the expenses amounting to over £1,000 a year, of which more than £700 was consequent on the Directors taking less fees, and in the ensning year the reduction in the expenses would be still larger. Mr. Lloyd had said that the Company was losing money everywhere in the concern. The subsidiary Companies, however, had worked at a profit, and the Egyptian Company had a larger profit. When the Directors had said that they thought it necessary that there should be such a committee as was now desired, he thought they were justified in saying so in view of the fact of what had been referred to concerning the consultative committee in connection with the powers which the Company had; and though they never came to the place, they could hardly say that they were denied the means of doing so.

Mr. AKERS: I shall deny that most certainly.

The CHAIRMAN said he agreed with the statement made that the consultative committee was a farce, but he thought that that was due to two of the gentlemen who had desired to turn it into something else very different from that of a committee of a consultative character.

Mr. ADDISON said that the Chairman denied the veracity of his account to the meeting of the origin of this movement, and he proceeded to tell what he had previously said on this point.

Mr. ROBINSON KENDALL said he thought it their duty to see whether the seemingly conflicting interests could not be reconciled, and with that view he asked if the Board would accept three gentlemen nominated by the requisitionists for the committee, if the Directors themselves nominated two others [No, no]. He thought that this suggestion might be wisely accepted in the interests of the Company, and that they ought not to have the Company's interests jeopardised by the appointment of a committee with hostile feelings who were determined to go against the Board. He moved an amendment in effect appointing a committee of five shareholders, to be composed of three directly nominated and elected by the meeting, and two nominated by the Board and elected by the meeting.

Mr. VEARES seconded the amendment.

Mr. E. B. Frost remarked that he failed to see anything in what the Chairman had said why the committee should not be appointed, and he thought if there was nothing to conceal that they would court investigation and inquiry. On the other hand, if there was anything to conceal, it was the duty of the shareholders to investigate and find out what was wrong.

Mr. PENDER, M.P., said he believed the whole affair was in a nutshell, and he asked the Chairman to accept what Mr. Lloyd had said he wanted—a fair, impartial, independent committee. He knew that when he left the Company he believed there was no company in a sounder position, and they had heard from the Chairman that its prosperity had materially increased since then. While he maintained that such meetings as this were, as a rule, detrimental to the credit and reputation of a company, he thought that this Company occupied such a position that it might be better to have a fair impartial investigation. The names should be suggested one by one, and then the shareholders should vote separately. He had a large interest in the Oriental Company, and a very large interest in the propress of electricity generally, and great difficulties had to be encountered. This Company only required careful nursing. They had got in India the best possible field for telephonic enterprise, while in Egypt, notwithstanding all the difficulties in that country, they had a most successful company there, and one which was likely to be a great deal more successful with the rebuilding of Alexandria. At Singapore they had a most excellent company, and altogther looking at the position which the Company occupied if they did not quarrel among themselves but would act in union and nurse their affairs, they might depend upon it they that they would come out not only with their money entire but with a very good income for it. He certainly thought the Board required strengthening, for it was weak, although that was from circumstances over which the present Board had no control.

A SHAREHOLDER asked if Mr. Pender would be disposed to act on the committee.

Mr. PENDER said he thought it would be unfair to the shareholders if he did.

Mr. BUCKLEY spoke of the benefits which the Company had derived in connection with the Indian Companies through the influence of Mr. Pender. He suggested, amid expressions of dissent, that two or three gentlemen should be invited by the Board to join them in looking into the affairs of the Company.

Mr. AKERS said it had been his opinion at least twelve months before the appointment of the consultative committee that there should be a committee of investigation, and he trusted that the shareholders would not on the present occasion allow themselves to be led away by any side wind to place any extra power in the hands of the Directors. The consultative committee which had been appointed was a compromise instead of a committee of investigation.

After further discussion on matters of a personal nature,

The CHAIRMAN said that the views of the Board on the subject of the committee were expressed in their circular. They had thought that with the freedom of access which they had offered to all the shareholders no committee was necessary. But he did not think it would be merely on the part of the Board sitting there to say that they would now oppose a committee of investigation. He had had no opportunity of consulting his colleagues on this point, and therefore he must be taken as speaking only for himself. He thought it was desirable that the matter should be settled to-day, and that a committee of investigation should be appointed, but he did think that it should be so constituted as that it would report fairly. He alluded to the large number of proxies which they had received on the faith of the statement made by them in their communication of the 29th November to the effect that if a committee of investigation (meaning always a hostile committee) should be appointed they would oppose it.

After further remarks from Mr. LLOYD, and some further discussion as to the manner in which the names of the committee should be submitted,

The CHAIRMAN put the amendment, which was lost on a show of hands. He next put the original motion, which was carried.

The following gentlemen were afterwards appointed the committee of investigation:—Messrs. William Edison, G. B. Frost, Martin Jaffé, T. Lloyd, and St. John Akers.

Mr. LLOYD said it was the general opinion that the Board was too weak, and they desired to strengthen it. He therefore proposed the election to the Board of the Right Hon. G. F. Cavendish Bentinck, M.P., Mr. St. John Akers, Mr. William Edison, Mr. John Battams, and Sir Alexander Armstrong.

The motion having been seconded,

An amendment was moved to the effect that the question of appointing Directors should be deferred until the committee presented their report. After some discussion,

The CHAIRMAN said that it was not the intention of the existing Board to remain responsible for the position of the Company with the committee going on, and therefore unless the meeting elected Directors they would be a company without a Board.

The amendment was then withdrawn.

The resolution as proposed was carried.

The CHAIRMAN said that notice had been given of a further resolution (relating to the remuneration of the Directors), but he would take the responsibility on behalf of the Board of withdrawing in.

The proceedings then terminated.

NOTES.

PATENTS.—The number of applicants for Letters Patent during the year just ended amounted to 17,110.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 26th Dec. amounted to £3,217.

APPOINTMENT.—Captain Beresford, R.E., succeeded Major Turner as Superintending Engineer of the Southern District of England on 1st January.

ELECTRIC LIGHT IN BERLIN.—The contract between the Berlin Municipal Authorities and Siemens u. Halske for the electric lighting of the Potsdamer Platz expires on 1st March, but is to be renewed.

THE MICROPHONE IN COLLIERIES.—The new microphone invented by M. Hipp, of Neuchâtel, is being tried at the Mariemont Colliery, Belgium, for signalling between the surface and the underground workings.

TRAIN LIGHTING.—On Tuesday last a successful experiment in train lighting was made on the South-Eastern Railway, two trains between London and Maidstone being provided with incandescent lamps, which gave a brilliant and steady light.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts for the week ended 26th December were £2,557, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

COMPAGNIE INTERNATIONALE DES TELEPHONES.—At the special general meeting on 18th Dec., it was decided to wind up this company, as reported in another column. The *bulletin* will therefore cease to appear, but will be continued in another form.

ELECTRIC ILLUMINATION OF THE ADELSBERG GROTTO.—This stalactite cavern is now illuminated by twelve 1,500-candle arc lamps, the light for which is reflected by the crystalline surfaces, revealing beauties hitherto unknown even to the guides.

POSTAL TELEGRAPH REVENUE.—The revenue of the Post Office telegraphs for the nine months just ended shows a decrease of £5,000, compared with a corresponding period in 1883. Mr. Childers estimated that there would be an increase of £55,000 for the whole year.

ATLANTIC CABLES.—The two Bennett-Mackay cables have been repaired, and the lines opened for traffic. The rate charged for messages was two dollars per word. In face of this competition the existing companies have also reduced their tariff from 2s. to 1s. 8d. per word.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th Dec. are £2,190, as compared with £2,251 in the corresponding period of 1883. The September receipts, estimated at £4,083, realised £4,143.

KABATH ACCUMULATORS.—We learn from the *Rivista dell' Electricità*, that these accumulators have been used in connection with Gaulard and Gibbs' secondary generators, by which the transformation may be effected, not only from series to quantity, but also from quantity to series.

THE TELEPHONE IN ITALY.—The Società Generale Italiana dei Telefoni has, with the co-operation of Commendatore Florio, of the Rubattino Florio Company, constituted a local telephone company, the Società Meridionale dei Telefoni, the chairmanship of which has been offered to Sig. Florio.

TEMPORARY LIGHTING.—The Società Industriale Franco-Italiana has provided a portable plant, consisting of dynamos, accumulators, incandescent lamps and conductors, for undertaking by contract, on the occasion of *fêtes*, &c., temporary lighting, as well as telegraphic and telephonic communication and protection from lightning.

ELECTRIC LIGHT AT THE PARIS EXHIBITION, 1889.—M. Eiffel has designed a wrought-iron tower, 300 metres = 984ft. high, for carrying powerful arc lights, capable of illuminating the whole Exhibition and its approaches, while, in case of war, a search light on the top would shed its rays over the country round for 60 kilometres or 40 miles.

PROPOSED EXHIBITION AT TRAUTENAU.—According to the German press, an exhibition of commerce, industry, electricity, agriculture and forestry, will be held in 1886 at Trautenau, the political centre of the Riesengebirge district. It is expected that the support of the various branches included in the scheme will make the enterprise a success.

INTERNATIONAL SOCIETY OF ELECTRICIANS.—The Société Internationale des Electriciens will hold its ninth ordinary monthly meeting on Wednesday next, 7th inst., in the hall of the Société de Géographie, Paris, when papers will be read on the Principal Applications of Electricity to Railways, by M. F. Rodary, and on an Electrical Meter, by M. G. Lippmann.

THE CREIL EXPERIMENTS.—It is hoped that the plant at Creil will be ready for working during the present month; and that the intended current of 20 amperes at 7,500 volts will then be generated for transmission to Paris. The French Government is imposing stringent regulations as to the protection of the conductors, so as to guard against accident.

BOILER SCALE AND ELECTRICITY.—A correspondent to the *bulletin* of the Compagnie Internationale des Téléphones states that existing boiler scale may be detached by keeping the poles of a 10 or 12-cell Bunsen battery connected with the ends of the boiler for 30 or 40 hours, and that afterwards the plates may be kept clean by a weaker current similarly applied.

THE LATE M. LATIGUE.—At the last meeting of the Société Internationale des Electriciens, the president, M. G. Berger, in speaking of the late director of the Société Générale des Téléphones, who was also one of the founders of the first-named society, said that without Latigue the Paris Electrical Exhibition of 1881 would certainly not have been so successful as it was.

GENERAL TELEPHONE COMPANY.—M. A. Berthon, chief engineer of the technical service to the Société Générale des Téléphones, has been appointed engineer-director of the construction and working department. The *Bulletin* says that M. Berthon, past president of the Société Amicale des Elèves de l'Ecole Centrale, is the first engineer to make a practical application in France of the Edison telephones.

INSTITUTION OF CIVIL ENGINEERS.—Yesterday was the anniversary of the foundation of the Institution of Civil Engineers, which was established on January 2, 1818. From a new list of members just printed it appears that there are now on the books twenty honorary members, 1,447 members, 1,889

Digitized by Google

associate members, 508 associates, 804 students, together 4,686, against the total at the same date last year of 4,443.

THE INTERCOLONIAL TELEGRAPHS, VICTORIA.—The last consignment of telegraph wires for the extra intercolonial lines between Melbourne and Albury had come to hand in excellent condition; and every effort was being made to push forward the construction of the new wires. It was expected that the work would be finished by November 20. The extra line from Sydney to Albury has been available for some time. —*The Colonies and India.*

LONG-DISTANCE TELEPHONY.—At the request of the Portuguese Minister of Public Works, M. Van Rysselberghe gave a lecture on his system, at Lisbon, before the King and Queen of Portugal, the Ministers, the high functionaries of State, and the leading scientific men. At its conclusion, oral messages were exchanged between the capital and Cintra; and the Belgian *savan* was warmly congratulated by the king on his important discovery.

UNION ELECTRIC LIGHT AND POWER CO.—By an order made on 6th of December, 1884, on the petition of Dillwyn Parrish, and Alfred Parrish, of 2, Copthall-buildings, E.C.; John Goddard, jun., of Elmer Lodge, Elmers End, Beckenham; and Jas. Fyfe, of St. Stephen's-chambers, Telegraph-street, E.C., electrician, it was ordered that the voluntary winding up of the Union Electric Light and Power Company be continued, but subject to the supervision of the Court.

ELECTRIC LIGHT AT THE ANTWERP EXHIBITION.—The Managing Committee intend to divide the lighting of the Exhibition into three portions, in one of which a single system will be chosen, in another all kinds of appliances for gas lighting will be admitted in competition, and for the third electric engineers and electric lighting companies, English included, are invited to go in for certain areas, as at the late Health Exhibition, in order to demonstrate the value and adaptability of their systems.

ELECTRIC POWER FOR THE ORLEANS RAILWAY COMPANY.—The Compagnie Electrique has put down electric plant at Vitry, for the Compagnie de Chemin de fer d'Orleans. A No. 5 electric generator, driven by a steam engine distant about 180 metres (590 feet), yields, at 1,100 revolutions a minute, a current the tension of which does not exceed 140 volts. The No. 3 electric motor, placed in a cellar, gives out 50 kilogrammetres (361 foot-pounds), working a rotary pump and other machinery.

ELECTRIC LIGHTING AT ANTWERP.—The Compagnie Générale d'Electricité is laying cables on the Callender system, for lighting the eastern district of the city by 6,000 Gülcher incandescent lamps, maintained by Gülcher dynamos. The cables are laid underground in cast-iron troughs of rectangular section, fitting one into another, and closed by wrought-iron cover plates, the interstices being filled up with pitch. This lighting plant, the most important yet undertaken by the company, is to be ready by February.

GADOT'S ACCUMULATORS.—Signor Paolo Gadot is stated by *Il Giorno* to have invented some new secondary batteries which have an electrical capacity almost double that of the Faure-Sellon accumulators. He makes four types, suitable to domestic applications, such as lighting, electro-deposit, and the working of small motors. The lead electrodes are, as usual, coated with oxide, but are immersed in a liquid, the composition of which is at present kept secret, and which, while effecting depolarisation, facilitates the attack of the metal plates.

THEATRE LIGHTING.—The contract for providing the two Court theatres of Berlin with 4,500 incandescent lamps has been entrusted to the Städtische Electricitätsgewerbe, who will lay the conductors during the winter, and install the lamps and internal fittings during the summer, when the theatres will be closed. At the new concert hall, Leipsig, 500 incandescent lamps are fitted to the gas brackets, and maintained by 120 Epstein accumulators, charged by a dynamo, driven by an 8-horse gas engine that is started about twenty-five hours before the light is wanted.

TRAVELLER WORKED BY ELECTRICITY.—For some years past a travelling crane has been worked by current at the Bourges Cannon Foundry in France; and M. Marinoni is now turning his attention towards applying the same system to a traveller 20 metres long and 7 metres high (65 by 23ft.), with a travel of 90 metres, or 295ft., at his Parls works. A No. 5 motor of the Compagnie Electrique makes the lift (up to six tons), while a No. 4 serves to effect the travelling motion. At 1,100 revolutions the generator gives out a current the E.M.F. of which does not exceed 250 volts.

TRANSIT TABLES FOR 1885.—We have received from Messrs. E. and F. N. Spon a series of tables computed from the "Nautical Almanac," for popular use, by Latimer Clark, M.I.C.E., M.S.T.E., &c., by means of which any one may obtain accurate time in any part of the world by a simple observation of the stars without any calculation. There are full directions for obtaining Greenwich time, local time in England and other parts of the world, and Greenwich time, as well as district time at foreign stations. But why in this high-pressure age are not the leaves machine-cut?

A POINT IN THERMO-DYNAMICS.—At the meeting, on 15th December, of the Paris Academy of Science, M. H. Lechatelier proposed to verify an important point in thermodynamics, if, in consequence of a progressive elevation of temperature, the heat of transformation changes rapidly (as is the case on the fusing of one of the bodies under consideration), the angular coefficient of the tangent to the curve of the pressures will also change rapidly. For this purpose he investigated the dissociation of hydrate of chlorine, and found an agreement between theory and practice greater than he hoped for.

WESTBOURNE-GROVE.—We understand that Mr. William Whiteley, of Westbourne-grove, has purchased the 1,000-light Ferranti machine which was recently exhibited at the Health Exhibition, and which obtained the gold medal. It is interesting to know that the machine of the same type, exhibited last year at the Fisheries Exhibition, was also purchased in that case for South Kensington. Mr. Whiteley, we understand, is not trying the Ferranti machine for the first time, but has had a small 200-lighter actually running 350 incandescent lamps; and, notwithstanding the severe strain, the machine is still in good order.

OURSELVES.—"*The Electrician*, Vols. XII. and XIII., shows the progress made from week to week in the development of electricity as the servant of man during the past year. This period has not been marked by any special activity on the part of the inventor. It will be remarkable rather for the survival of the fittest, for reductions of capital, liquidations, and amalgamations. And those who desire to trace the history of the critical struggles of the various companies and inventions to survive these days of public suspicion and neglect will find all they require in these volumes of *The Electrician*, besides much of interest concerning the telegraph and the telephone."—*Pall Mall Gazette.*

Digitized by Google

ABUSE OF THE TELEGRAPH.—We recently had occasion ot denounce gambling by telegraph; and we would now call attention to another species of the vice, as real if not so ostensible. Since the hourly variation of prices at the Stock Exchange has been telegraphed to a dozen different offices in the City, outsiders have been enabled to deal almost as closely as members; and their number has increased while their status has decreased in inverse ratio. The Committee of the Stock Exchange have this matter under consideration; and it seems not unlikely that the "tape system," as it is called, will be excluded from the hallowed precincts of the Exchange—that is, supposing the Committee are in earnest about the matter, and the outside gambling fraternity does not prove too powerful.

GAS OR ELECTRIC LIGHT.—The question as to the relative economy of gas and the electric light was lately discussed by the Société Industrielle du Nord de la France, when a large number of manufacturers who had adopted one form or other of the electric light expressed themselves highly satisfied. After a report presented by M. Gaillet on various electric lighting installations, M. Melon, a gas engineer, spoke in favour of gas, especially on the score of economy. He attacked the installation of the Magazins du Printemps, Paris, and stated that such an establishment at Lille, with gas at 12 centimes per cubic metre, would effect a saving of 21 per cent. by using gas instead of electric light. This is probably the case, though far from being so at Paris with gas at 30 centimes per cubic metre.

THE TELEPHONE IN FRANCE.—By an arrangement made between the French Minister of Posts and Telegraphs and the Société Générale des Téléphones, subscribers to the Paris Telephone Exchange will, in a short time, be able to despatch and receive their telegraphic messages by telephone, a telephone service, to be available day and night, being now in course of organisation at the Central Telegraph Office. Such telegrams will not be charged extra; but the telephone subscribers must pay an additional 50f. or £2 per annum. M. Van Ryssel-berghe, of long-distance telephony fame, has had an interview with M. Cochery, the French Postmaster-General, with reference to telephonic communication between Rouen and Havre, in the telegraph offices of which towns the necessary arrangements are already in progress.

THE SENEGAL CABLE.—A Reuter's telegram to the *Standard*, dated Lisbon, 29th December, says that on that day the Spanish Colonial Minister went on board the steamer "Silvertown," which is about to sail for Africa to lay the Senegal cable, and to make soundings preparatory to the laying of the Portuguese cable. After inspecting the ship, the Minister, who was accompanied by Mgr. Vanutelli, the Papal Nuncio, M. de Laboulaye, the French Minister, and Baron Greindl, the Belgian Representative, delivered a speech, in which he expressed the hope that the civilising work about to be begun—the initiative of which emanated from Portugal—would be successfully accomplished. Portugal had already rendered services to humanity on the African Continent; and it was to be hoped that this new line of electrical communication would serve as a bond of union between Portugal and the Powers interested in the development of their West African Colonies.

SERMONS BY TELEPHONE.—In this connection, Mr. J. D. Miller, one of the district managers of the National Telephone Company, writes to the *Aberdeen Herald* as follows:—"Sir: With reference to the leader in your paper on the American article of 'Talmage on Tap,' it ought to be made known to your readers that all that is hoped for in the connection of the Brooklyn Tabernacle with the telephone exchange there has already taken place, with brilliant success, in this country. On this company's system, churches in Birmingham and Bradford have been in connection with the exchanges in these towns for two years now. The first connection of a church with a telephone exchange in this country was that of the George-square Congregational Church in Greenock, which I connected up so far back as June, 1882, ever since when sermons and the entire services have continued to be 'served hot' each Sunday to a number of private residences in Greenock, and at the same time several in Glasgow—a distance of over 22 miles."

ROYAL REWARD FOR TELEPHONING AN OPERA.—The King of Portugal has just conferred the honour of Cavalliero do Christo on Mr. Alan Danvers, engineer and manager to the Edison Gower-Bell Telephone Company at Lisbon. Mr. Danvers has received this distinction in consequence of the following interesting circumstances:—Some little time ago the King of Portugal was prevented from attending the first performance of the opera "Lauriana" through the death of the Princess of Saxony; and neither the King nor the other members of the Royal Family would have heard anything of the opera, had not Mr. Danvers come to the rescue and suggested that he should telephone the opera from the house to the Ajuda Palace. The King, delighted at the proposal, immediately acquiesced. The result proved most satisfactory, as both the music and the words are stated to have been perfectly distinguishable; and the King shows his appreciation of the fact by conferring this honour of knighthood on Mr. Danvers.

EASTERN COMPANY'S CABLE IN DANGER.—The indecision of the Government in enforcing the provisions of the Foreign Enlistment Act, which has already been proclaimed in the former place, is attributed in well-informed quarters to the weakness of our squadron in the China Seas. An incident which strongly reveals our weakness there has hitherto been kept secret, and has only become known in London quite recently. After the bombardment of Foochow, the pirates in the Min River, taking advantage of the disorder, attacked the hulk which forms the terminus of the Eastern Telegraph Company's cable at Sharp's Peak, near the mouth of the river. The *employés* were compelled to fly for their lives, leaving the hulk and instruments in the hands of the pirates. An application to Admiral Dowell for a gunboat to protect the station of this important English company was met by the reply that there was not one to spare; but the English Admiral applied to Admiral Courbet to give the protection which he could not afford himself. A French gunboat was accordingly told off for the duty.—*Pall Mall Gazette.*

ELECTRIC LIGHTING IN GLASGOW.—The Town Council of Glasgow appear quite resolved not to permit any general scheme of electric lighting to be carried out by companies or private individuals within the municipality. When the subject was before the Council some time ago, a main objection urged was that the overhead wires were becoming far too numerous in the city for the public safety. This was one of the reasons brought against the application of Messrs. Woodhouse and Rawson, electricians, of London. Bearing this in mind, doubtless, a local firm, Messrs. Muir and Mavor, recently asked permission to open up Miller-street, Ingram-street, and Hanover-street, for laying underground wires, for the purpose of supplying electricity, which is generated in their premises in Miller-street, to the General Post Office. The Council have declined to sanction the work. As owners of the gasworks, the Corporation is deeply interested in the question of public lighting. They make no objection to firms supplying their

Digitized by Google

own wants by electricity—probably they lack the power to interfere in such cases. But now it is proposed to sell or trade in the light, the Council, drawing the line at that point, step in with their prohibition. They believe that if electric lighting is to become general at any future time they ought to have the exclusive right to supply it as the representatives of the community.—*Gas and Water Review.*

FIRE AND THE TELEPHONE.—Mr. C. G. Wright, the Edinburgh district manager of the National Telephone Company, writes as follows to a northern contemporary:—"In your issue of December 17th there appeared an account of a fire which occurred at the Tyrie Bleachworks, near Kirkcaldy, early on the morning of the previous day. It is stated that 'on the burgh fire brigade arriving on the scene, the roof was found to have fallen in.' Another account states that on the discovery of the fire 'a man was despatched on horseback for the Kirkcaldy fire brigade.' The owners of the Tyrie Bleachworks were lucky in having a horse and rider so handy, but had they possessed communication with the Kirkcaldy Telephone Exchange (which is open day and night), the fire brigade would have arrived at the scene about the time that the man on horseback was galloping up to the fire station with the alarm, and the roof would probably have been standing now. A marked contrast to this occurrence was the fire at the Kirkcaldy Linoleum Company's works on June 30th last. In that case communication with the Telephone Exchange existed, and by its aid the burgh fire brigade and the private engines of several firms were called with such promptitude that, although the building and contents were valued at £40,000, and the fire, when discovered, had obtained considerable hold, the total damage done was under £500."

INTERRUPTION OF THE ST. VINCENT CABLE.—At about 11 a.m. on the morning of the 28th November, the new cable to St. Vincent was suddenly interrupted. At first it was considered that a land-line had "gone wrong;" but a visit to the cable-house settled the matter, the tests pointing to the break being a very short distance from shore, though in comparatively deep water. Our superintendent at first thought of attempting the repair himself; but Mr. Blandy was unwilling to risk one of his lighters, as the weather had been and still was threatening. Accordingly the "Kangaroo" arrived at Madeira, December 15th, and found the break to be a little over half a knot from the cable-house. We are now "through," and working well. A curious feature in connection with this rupture, evidently the work of a ship's anchor, was that although our end of the break made "earth" after a fashion, the broken extremity of the St. Vincent end was completely sealed by the gutta percha which had been pulled and pressed over it. A better or more effective seal, they say, could not have been made by a jointer, and on its being tested after being brought aboard it showed no loss whatever. As might be expected, from the time the interruption took place, St. Vincent's tests gave as results the D. R. of all but the entire cable. On the Madeira end being brought aboard, it was found to be almost sealed—in fact, none of the conductor could be seen, but only felt. The electrical resistance of this break was about ten or twelve units.—*Monthly Correspondent, Madeira.*

PHOSPHOR BRONZE CONDUCTORS.—*A quelque chose malheur est bon*, or "'Tis an ill wind blows nobody good," was exemplified in Brussels on the 9th December last, when a gale broke 130 telephone wires, all of iron or galvanised steel except two, which were of phosphor bronze and cut at the fastening. *Apropos* of this *contretemps* M. Emile Bède points out in *L'Ingenieur-Conseil* that 2-mm. iron or steel wires are not to be depended upon, on account of their being subject to the action of oxidation and also disintegration from smoke. He has accordingly employed phosphor bronze for the additional lines which he has put up in Brussels and also for the whole of the Ghent system. Though their diameter is only 0·8 mm. they stand, while iron and steel wires of 2 mm. diameter give way after four years. The Bell Company now uses phosphor bronze wires of 1·25 mm. diameter, which, besides being easier to put up, offer a greater security against accidents. M. Bède states that all the 0·8 mm. phosphor bronze wires which he has tested, after being up a year, have preserved both the diameter and the tenacity that they had originally. He looks forward to the time when not only telephone but also telegraph lines will be laid with phosphor bronze wires of high conductivity. Although telegraph wires of 4 mm. diameter are capable of standing longer than telephone wires of 2 mm., on account of the greater reduction in sectional area of the latter by an equal amount of oxidation, while their tension is less on account of the supports being nearer together, they soon become bad conductors, because a half-millimetre of oxidation, reducing the diameter of the wire from 4 to 3 millimetres, increases the resistance in the ratio of 9 to 6.

SHIP LIGHTING.—The Swan lamps on the Great Eastern Company's ss. "Norwich" have now been in use a year and seven months. Though only guaranteed for 1,000 hours' service, they have, with the exception of those accidentally broken, held out for more than four times that period. The carbon filaments of a few are now showing signs of dwindling away; and the chief steward has put one up in his cabin, so as to watch and see how long it really will last. We recorded, a month or two ago, the only hitch that had occurred in this remarkably successful lighting; and that was due to the belt slipping off. This belt, of cotton, which has been on since the commencement, gave way suddenly the other night; but a new one was fitted on directly, with a cessation of less than an hour in the electric lighting. It is hoped that the difficulty of yielding suddenly without warning is now got over by the use of a silky cotton belt, or rather rope, with a very long splice. The 1st and 2nd engineers of the vessel have fitted 14 extra lamps in the engine room and in their own cabins, without any assistance from electricians, the light from the 60 lamps in the saloon being rather improved than otherwise. The dynamo may be run at a still higher speed if necessary, so the engineers propose to put up lamps in the second-class cabin, the smoking saloon, and the captain's cabin, all to be maintained by the same dynamo. As the navigation of the Scheldt is so difficult that it has to be accomplished by daylight, thus involving an early start in the winter months, and as the Dutch Government does not seem inclined to improve the channel, we would recommend the company to be independent of daylight by fitting up a couple of projectors, with powerful arc lights, so as to illuminate the way ahead, and therefore give more time before starting from Antwerp.

THE E.M.F. OF BATTERIES.—When a battery is formed by a single liquid (says D. Thommasi in *Kosmos*) its electromotive force is equal to the difference of the thermic constants of the metal attacked, and of the disengaged hydrogen, divided by the volt expressed in *calories* (463). If it be desired to determine the electromotive force of the copper-zinc couple immersed in diluted sulphuric acid, according to the general formula $E = \frac{\theta H^2 - \theta Zn}{V}$ or $E = \frac{2 \times 61{\cdot}5 - 88{\cdot}8}{46{\cdot}3} = 0{\cdot}7386$ volt, the thermic constant of hydrogen being 61·5, and that of zinc 88·8. The E.M.F. of the same couple is found by direct experiment to be 0·81 volt. If this value is greater than that shown

Digitized by Google

by theory, the circumstance is due to secondary actions independent of the chemical reaction of the battery. In fact, the E.M.F. of a couple with single liquid varies with the nature of the inactive metal, and may attain, with carbon for instance, as much as 1·4 volt (at the instant the circuit is closed), although the heat disengaged by the chemical reaction is always the same. The E.M.F. of a single-liquid battery is the same, whatever be the nature of the acid employed, and does not depend on the metal attacked. An exception must, however, be made in the case of acids capable of being reduced by hydrogen, or more exactly by H + calories, as in the case of chromic, nitric, and other acids. These reductions were formerly explained by admitting a special condition of hydrogen, the *nascent state*; but, since 1877, the author pointed out that, at the moment hydrogen is set free, it owes its reducing properties, not to its nascent state, but to the quantity of heat disengaged. The law above enunciated will not hold good if the metal, which should be inactive, is partially attacked by the liquid, as in copper-zinc, zinc-aluminium, and other couples, immersed in hydro-chloric, hydro-bromic, and other acids.

Electric Light at Temesvar.—With respect to the lighting of this, the third town in importance of Hungary, Mr. Frank Schlösser, secretary to the International Electric Company, writes to the *Daily News* as follows:—Referring to Reuter's telegram of 25th ult., to the effect that the town of Temesvar, in Hungary, was left in darkness in consequence of the breakdown of the electric light system which has been established there by this company, I am instructed by my Board to ask you to be so kind as to give publicity to the fact that the interruption referred to, which occurred on one night only, was not caused by a breakdown of the electric light system, but by a sudden failure of the water supply for boilers and condensers consequent upon the blocking up of the Bega Canal by an exceptionally heavy fall of snow followed by hard frost. With the exception of the above single interruption, against the repetition of which the necessary precautions have been taken, the lighting by electricity of the whole of the public thoroughfares of Temesvar (over 40 miles in length) has been in continuous and perfectly satisfactory operation since the first of November last. The experts called in by the Town Council to examine and report on the works were on the spot at the time of the accident, and were able to verify its cause. The result of the report they have since sent in has been a unanimous vote of the general assembly of the Town Council to accept for a permanency the electric lighting of the streets, as complying with the terms of the contract made by the town with the International Electric Company. The first permanent establishment of a system of electric lighting for a whole town is a matter of considerable public as well as historical importance, because most Continental concessions for the lighting of towns by gas contain a clause rendering it obligatory upon the concessionaries to supersede gas by any other system of illumination which may have proved itself superior by practical experience.

Compounds obtained by Means of Gas Batteries and the Silent Discharge.—The apparatus employed by A. Figuier (*Compt. Rend.*) consisted of two hollow graphite cylinders closed at one end, and coated internally with spongy metal or spongy carbon so as to prevent polarisation. These cylinders were supported by a lid which closed hermetically the vessel containing the liquid conductor, the latter being alkaline when the product of the reaction was acid, and *vice versâ*. In some cases the gases were subjected to the silent discharge before being placed in the battery. The compounds produced are formed in contact with the poles, and in greater abundance at the positive pole. Although the current produced may be very feeble, the energy of the reaction may be relatively large. In the following table the substance placed second constituted the positive pole:—

Air and sulphurous anhydride	produce	sulphuric anhydride.
Hydrogen and chlorine	,,	hydrochloric acid.
Oxygen and chlorine	,,	chloric acid.
Nitrogen and oxygen	,,	nitric anhydride.
Hydrogen and nitrogen	,,	ammonia.
Carbonic oxide and sodium carbonate	,,	sodium oxalate and formate.
Ethylene and oxygen	,,	formic & acetic acids.
Hydrogen & carbonic anhydride	,,	formic & acetic acids.
Methane and carbonic anhydride	,,	acetic acid.

The ozonisers employed were provided with armatures coated with platinum black, and were so arranged that their temperature could be raised. Under the influence of the discharge oxygen combines directly with sulphur, selenium, chlorine, iodine, and bromine, but has no action on tellurium. Hydrogen combines with sulphur, selenium ordinary phosphorus and nitrogen, but has no action on tellurium, arsenic, antimony, and red phosphorus. Oxygen oxidises formic acid and formates, carbonic oxide combines with hydroxides, &c.—*Jour. Chem. Soc.*

Treating Sugar by Electrolysis.—The complete extraction of juice from what is generally but erroneously called beetroot—*betterave* is really mangold wurtzel—is rendered very difficult on account of the presence of alcalis in the juice, which prevent the crystallisation of the sugar. A process for neutralising these alcalis has been patented by M. Despeissis, whose invention has this further advantage, that the salts contained in the saccharine solution are obtained in such a manner that they can be turned to profitable account. The process is founded on the fact that, if an electric current be made to traverse a liquid containing a salt in solution, the base of this salt, which is decomposed, is transferred to the negative, and the acid to the positive pole. If there be a porous diaphragm between the two poles, so that the current may pass, but the two liquids can only mingle slowly, the acid and the base of the salt, set free, cannot immediately recombine. The current is to be produced by dynamos or batteries; and the electrodes that M. Despeissis prefers to use are those of carbon or platinum, while the porous jar may be of unglazed clay, carbon, or parchment. During the electrolysis, it is especially the carbonic acid which is disengaged; and this acid, which partially remains in solution, is not injurious to the sugar, while it may also be neutralised by lime. When the liquid is raised to a suitable degree of heat, this carbonic acid is neutralised by the formation of insoluble carbonates, which, on being deposited, also take with them the colouring matters. The syrups and molasses may be treated by the action of heat; and this method has the advantages, that the hot liquid offers less resistance to the electric current, and is sufficiently fluid to render the addition of water unnecessary. Moreover, the high temperature facilitates the escape of the gases which are not deposited on the electrodes. The elimination of the alcalis is effected by means of a filled vessel placed in the juice, and in which the negative electrode is immersed; it is also advantageous to immerse the positive electrode in a porous jar filled with water, and placed in the body of the juice. In this manner the acids and the iron contained in the saccharine matter go to the positive electrode, and the alkaline bases to the negative electrode. The porous jars facilitate the separation of these substances, which are injurious to the saccharine juices, thus permitting a higher proportion of crystallisable sugar to be obtained.

THE STEAM ENGINE INDICATOR.—V.

BY AMICE.

There is yet another indicator which, by reason of its good qualities, and especially of its steadiness in working at high speeds, has claimed a good deal of attention amongst English mechanicians during the past year or so, namely, the indicator made by the Crosby Steam Gauge and Valve Company, of Boston, U.S., a company whose London office is in Cross-

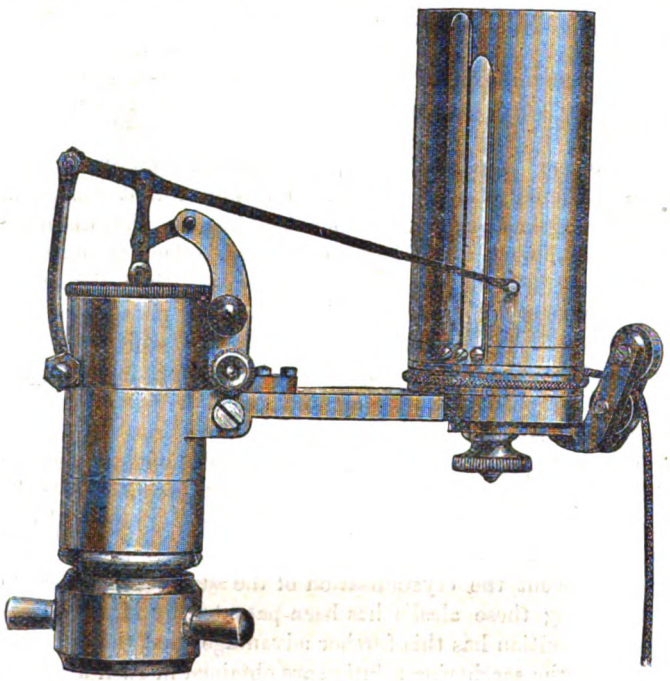

FIG. 20.

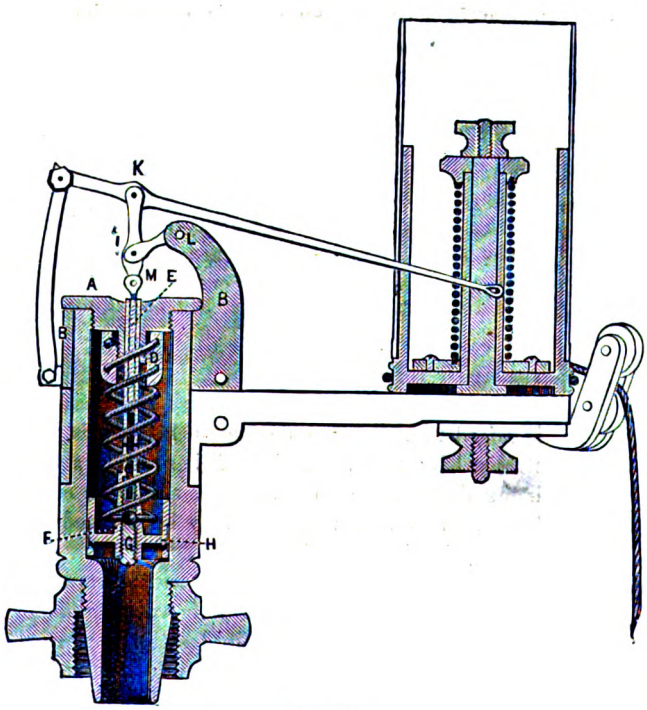

FIG. 21.

street, Finsbury. This indicator we must illustrate and describe, as it affords a good example of that capacity for the development of an invention which seems to characterise American inventors of a large class, and it is noteworthy that the indicator which has held its own for so many years, viz., the Richards, was also an American development of the English invention.

The Crosby indicator is illustrated in perspective and in section by Figs. 20 and 21. Both these views show the lightness of the pencil motion, the general simplicity of the whole indicator, the simple arrangement of piston, piston-rod, and spring. The spring differs in one feature from those used in any previous indicator, namely, that its lower end is not rigidly fixed by a screwed collar on the piston-rod, but the spring itself is a double twist of one piece of steel wire, to the middle of which is attached a small steel sphere, which sits in the hollow piston rod, as shown in Fig. 21, so that the spring is free to adjust itself and to allow the piston and rod to move freely and without the slight friction which want of absolute centralism of the internal and external screws of the usual arrangement sometimes cause. The Crosby spring, seen at full size in Fig. 22, is screwed rigidly to the top cover, as in other indicators, so it needs to be as accurately made in this respect; but the freedom given at the piston end is undoubtedly of advantage, while the lightness of that end is of much greater importance, as this part receives the same motion as the piston.

Turning to Fig. 22, it will be observed that the head by which the spring is held to the cover A (Fig. 21) is large and heavy. Here, however, size is of great advantage, for it secures the advantages of a method of holding that end of the spring which enables the manufacturers to adjust the scale of the spring with great facility. In the ordinary way it is customary to effect the final adjustment of the scale of springs, or, rather, to give them the necessary range with a given amount of pressure by grinding the wire of the spring after it has been tempered. This, it need hardly be said, is not a simple operation, and to some extent affects the uniformity of the sectional area of the spring wire, and therefore detracts from

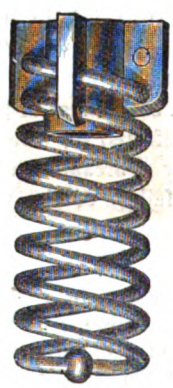

FIG. 22.

the desired uniformity of flexure throughout the length of the spring. In the Crosby spring, however, the two ends of the wire are (the spring being like a double spring) screwed or threaded into the holes, drilled on the wings of the head, and all that need be done to adjust their scale is to screw them in or out of this head. During compression, spiral springs often compress round an axis which is not either a perfectly right line or a fixed one. The advantage of the freedom given by the ball joint connection of the piston and spring is therefore of much importance, considering that it is the attention to these many small things which makes up the superiority of the modern indicators. It will be seen from Fig. 21 that the joint part E of the piston rod screws into the upper part of the tube C, which, at its lower end, screws into the upper part of the boss of the piston H. The screw G in the piston is to adjust the grip on the ball joint of the spring. At F round the piston are small chambers into which steam finds its way to cause the piston to maintain a central position in the cylinder.

Turning to the paper drum, seen in section in Fig. 21, it will be observed that round the central spindle is a spiral spring. The upper end of this spring is fixed by the nut and collar at the top of the spindle, the lower end being attached to the bottom part of the drum. By loosening the upper nut and turning the collar either the one or the other way, and then setting it fast by the nut, greater or less tension may with facility be put upon the spring to suit the speed at which the engine to be indicated is running. This spiral spring does not give a uniform tension throughout the rotation of the

Digitized by Google

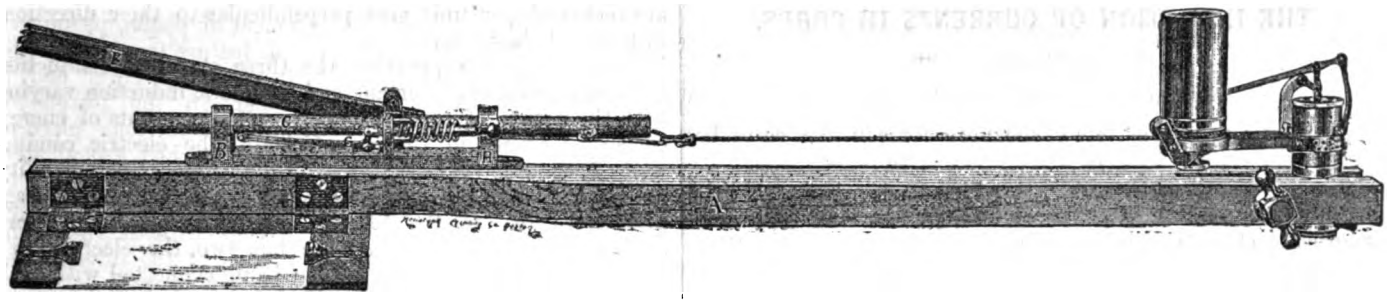

Fig. 23.

drum. It happens, however, that the increasing resistance of the spring as the cord pulls it to the end of the stroke, is exactly what is required for high speed indicating. For instance, at the end of one and the commencement of another stroke the indicator drum is at rest for an assignable length of time whatever the speed of the engine. From rest it is jerked into motion, in some cases of very high velocity. When this is the case the string has considerable work to do in overcoming the inertia of the drum. At this period the spring should offer only sufficient resistance to the movement of the drum to prevent the drum from making any back lash movement at the first jerk of the string. On the other hand, at the end of the out stroke of the string, the tension may and should be higher; the string would be able to stand the higher pull, as it and the drum will have been falling in speed as the steam engine is finishing its stroke, and the higher tension of the wound up spring will enable it to the better overcome the inertia and start the drum on its backward rotation.

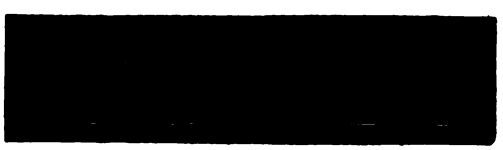

Fig. 24.

A very interesting illustration of the reality of the varying stress upon an indicator string, and therefore of the necessity of an oppositely varying tension on the drum spring, is given by the Crosby Company, as obtained by means of an instrument, the invention of Mr. G. W. Brown. This instrument is illustrated by Fig. 23, and diagrams taken by its aid, showing the variation in the tension on the string, are given in Figs. 24 to 27. If a perfectly inextensible string could be obtained, the difference of tension would make no difference in the steam diagram, and even with the good string ordinarily used there is barely any appreciable effect on the diagram. The indications are, nevertheless, more likely to be accurate when the whole indicator works smoothly than when otherwise,

Fig. 25.

so the results obtained by the instrument shown at Fig. 23 are in themselves interesting. The drum spring testing instrument consists of a wooden plate, A, to one end of which is fastened the brass frame B B, carrying the slide C with its cross head D. The head of the spring F is screwed to the cross head, while the other end is connected with the bent lever G, carrying the pencil. The connecting rod E, which moves the slide C, receives its motion from a crank not shown in the illustration. The swinging leaf holds the paper on which the diagram is to be taken. The indicator to be tested is clamped to the plate as shown, and the drum cord connected with the free end of the spring. The crank is made to move at the speed at which it is desired to test the drum and spring. The paper is then pressed up to the pencil and the diagram taken. If the strain on the cord is constant, the lines which represent the forward and return strokes will be parallel to the motion of the slide, but, if the strain is not constant the pencil will rise and fall as the strain is greater or less. The line below the diagram is the line of no stress, and is drawn when the cord has been detached from the indicator. In the diagram, horizontal distance represents the position of the drum, and vertical distance represents the strain on the cord. The perfect diagram would be two lines near together and parallel to the line of no stress, and would represent a constant stress, and consequently a constant stretch of the cord, from which no error would result.

The diagrams, Figs. 24 to 27, are shown two-thirds their original size.

Fig. 24 shows how, with a Thompson indicator drum, the stress on the string at 250 revolutions per minute fluctuated from but a slight one to a high one, falling again before the end of the stroke, when it rose to the point from which it fell, rose and fell to the starting point. Fig. 25 shows the stresses

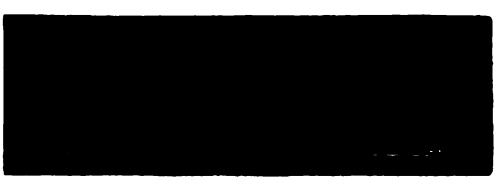

Fig. 26.

as obtained by Messrs. Crosby with their own drum spring; here the stresses become so near as to be almost a single stress. Fig. 26, also obtained by the makers themselves, is from a Tabor indicator drum at 400 revolutions per minute, while Fig. 27 is from a Crosby drum at 450 revolutions. In both Figs. 24 and 26 the straight dotted line is merely to connect the two points at the ends of the stroke, to show the departure of the stresses from a uniform rise and fall with the stroke. These diagrams have an interest from a mechanical point of view apart from indicators themselves. They serve to show how varied may be the stresses where uniformity, or approximately uniform rise or fall, might be expected.

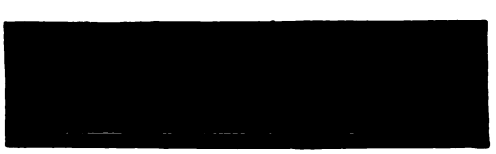

Fig. 27.

The guide pulleys seen in Figs. 20 and 21 are adjustable as to position by means of the nut below the drum, so that the string may be led in any desired direction.

The spring clips on the Crosby drum are, it will be seen, not of equal length. This is an apparently small invention, but it really is one which saves a great deal of trouble. It makes the application of the indicator paper very much easier and quicker than as ordinarily made.

In our next we shall deal with the use of the indicator.

Societe Generale des Telephones.—In the week ended 25th Dec., this company booked a dozen new subscribers in Paris; and in that ended 20th Dec., three at Havre, one at Lyons, and one at Marseilles.

THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONCLUDED FROM PAGE 107.)

Now let a normal system of magnetic force in the cores be

$$Am_{12}J_0(n_{12}r_{12})e^{Dt},\ Am_{13}J_0(n_{13}r_{13})e^{Dt},\ \&c. \quad . \quad (139)$$

merely changing the subscripts in passing from one branch to another. Here D is the same in all. That makes it a normal system. Again, the n's are known in terms of the D, by

$$4\pi\mu_{12}D = -n_{12}^2 P_{12},\ \&c.$$

Finally, the m's in (139) are a set of ratios to be found, and A is a common factor, fixing the actual size of the system. We have also

$$\Gamma_{12} = Am_{12}J_0(n_{12}c_{12})e^{Dt}/4\pi N_{12},\ \&c. \quad . \quad (139a)$$

Inserting this expression for Γ_{12} in (138), we get, with $t=0$,

$$P_1 - P_2 = \Gamma_{12}\frac{y_{12}}{x_{12}} \quad . \quad . \quad . \quad . \quad . \quad (140)$$

where $x_{12} = J_0(n_{12}c_{12})$, and

$$y_{12} = \{[R_{12} + (L_{12} - M_{12})D]J_0(n_{12}c_{12}) - S_{12}n_{12}J_1(n_{12}c_{12})\} \quad (141),$$

as in the last section. Here y_{12} and x_{12} are constants; also (140) would be the expression of Ohm's law if y_{12}/x_{12} were the resistance of the branch 1, 2, and there were no impressed force. So all we have to do is to put $C_1=0$, $C_2=0$, &c., $P_q=0$, in equations (131), and write x_{12}/y_{12} instead of K_{12}, to get the potential equations. But, the left members being now zero, we have

$$Z = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (142)$$

necessarily. This is the determinantal equation of D, when in the full expression for Z we write x/y for K. It should be cleared of fractions to avoid missing roots. Thus, the expressions (136) equated to zero, with x/y, as defined in (141) put for every conductivity, and cleared of fractions, will be the determinantal equation when every branch in the diagram contains a coil with a core. The ratios m in (139) next have to be dug out of the potential and continuity equations. That done, there is only left the size of A to be settled. Given the state of magnetic force h in the cores, and the coil currents γ at the moment $t=0$, A is to be found by the property of the vanishing of the mutual energy of a pair of normal systems, which makes the mutual energy of the given system with respect to a normal system, as defined in (139) and (139a), with $t=0$, equal to twice the energy of the normal system itself, and gives

$$A = \frac{\Sigma\tfrac{1}{2}\mu l\int hmJ_0(nr)rdr + \Sigma(L-M)\gamma mJ_0(nc)/4\pi N}{\Sigma\tfrac{1}{2}\mu l\int m^2\{J_0(nr)\}^2rdr + \Sigma)L-M)\{mJ_0(nc)/4\pi N\}^2} \quad (143).$$

Here the Σ's indicate inclusion of all the coils, so no suffixes are written, and the integration is from the axis to the boundary in every core. With this, we leave the combination. It is not patented, and is freely given to the world, without money and without price.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

Conductivity, Capacity, and Permeability.

In the electromagnetic scheme of Maxwell there are recognised to be three distinct properties of a body considered with reference to electric force and magnetic force, viz., conductivity, electrostatic capacity, and magnetic permeability. The body may support a conduction current, it may support electric displacement, and it may support magnetic induction. These three phenomena may, and in general do, coexist at any one point. Quantitatively considered, they are all vector magnitudes, having definite directions as well as strengths, which are reckoned per unit area perpendicular to their directions in terms of chosen units.

The facility of supporting the three states of conduction current, electric displacement and magnetic induction varying with the nature of the medium for equal amounts of energy concerned, brings in three coefficients, the electric conductivity k, the electric capacity c, and the magnetic permeability μ. At first sight it might appear as if three other vector magnitudes related to the former by these coefficients were involved; but in reality there are but two, the electric force and the magnetic force, the former being connected with both the conduction current and the displacement.

First we have Ohm's law. C being the conduction current density, E the electric force, and k the specific conductivity,

$$C = kE \quad . \quad . \quad . \quad \text{(Conduction current)} \quad . \quad . \quad . \quad (1)$$

Far more is known about conductivity than about capacity or permeability. In an unstrained isotropic metal, k appears to depend on the temperature only, and not to vary rapidly with it. That is, k is practically a constant, which simplicity is of great utility. Within wide limits k is independent of the current or the electric force.

The range of conductivity in different media is very great. From the conductivity of copper to that of cold glass is such an enormous range as to compare with astronomical ratios, and it speaks well for electrical science that it can compare definitely such widely differing magnitudes. But why be satisfied with copper? The discovery of a well-stocked mine of a material possessing, with other necessary qualities, a conductivity say ten times that of copper, would effect a revolution in the practical applications of electricity. Let it be looked for. There is a fortune in it, when found. There is some reason to believe that there are many of these mines in Spain; probably, though this is uncertain, in the neighbourhood of the old castles.

Dry air in its ordinary state appears to have no conductivity. But it is a vacuum that is the perfect non-conductor in Maxwell's theory. Where there is no matter, in the ordinary sense, there is no dissipation of energy; and ether, whatever it be, is perfectly conservative and non-dissipative, dynamically considered. Dissipation of energy is a necessary accompaniment of a conduction current, so far as is known; though of course a perfect conductor can be imagined in which a continuous current developed no heat. But ether cannot be this perfect conductor consistently with the propagation of magnetic disturbances, for none can be propagated in a perfect conductor. Grant that they are propagated in pure ether (space from which all "matter" has been removed) without loss of energy in the medium, and it follows that ether is the perfect non-conductor. This, however, somewhat anticipates electric displacement and magnetic induction.

Equation (1) is a vector equation. In an isotropic medium k is a scalar constant. We may symbolise E, C, or other physical vector magnitudes by geometrical vectors, lines drawn of the proper lengths and in the proper directions. Thus E is one vector, C is another, and when, as ordinarily, k is a scalar constant, (1) says simply that C and E are parallel, and that C is k times as long as E. Vector quantities are compounded like velocities; in a vector equation containing n vectors, separated by + or − signs, the n vectors form the n sides of a polygon. But two straight lines cannot enclose a space, so in equation (1) C and kE are parallel and equal.

But in a body eolotropic as regards conductivity, C and E are only exceptionally parallel. Using the same equation (1) to represent the relation between them, k, from being a scalar constant, becomes a linear vector operator; kE must be regarded as a single symbol, being E operated upon by k in a certain manner, turning it into a new vector kE. The operation is a little complex when expressed in Cartesian co-ordinates referred to any axes, so it is better to define once for all the meaning to be attached to k when eolotropy is to be included, and then use equation (1), rather than be repeating the Cartesian operations over and over again. The following defines the operation k, and the same will serve for c and μ later. First let there be no rotatory power. Then in three directions, mutually perpendicular, fixed in the body at the point considered, depending on

Digitized by Google

its structure there, Ohm's law, isotropically considered, is obeyed. That is to say, if electric forces E_1, E_2, E_3 act successively parallel to the above mentioned directions, or principal axes of conductivity, and C_1, C_2, C_3 be the corresponding currents, C_1 will be parallel to E_1, C_2 to E_2, and C_3 to E_3, and we shall have

$$C_1 = k_1 E_1, \quad E_2 = k_2 E_2, \quad C_3 = k_3 E_3, \quad . \quad . \quad . \quad . \quad (2)$$

where k_1, k_2, k_3 are scalar constants, being the principal conductivities. From this we find the current when the force acts in any other direction than parallel to one of the principal axes. For if E be the force, let its components parallel to the axes be E_1, E_2, E_3; the components of the current will then be C_1, C_2, C_3, as defined by (2). Compounding them, we get C. Thus the relation of C to E requires a knowledge of the principal conductivities and the directions of the principal axes.

But should the body possess rotatory power, the above process is incomplete. Let ϵ be a vector, directed parallel to the conductivity axis of rotation, and of length properly chosen, then to the current as found by the above process must be added another current expressed by

$$V\epsilon E, \quad . \quad . \quad \text{(Vector product.)} \quad . \quad . \quad (3)$$

which stands for a vector whose direction is perpendicular to the plane containing ϵ and E, and whose length equals the product of the length of ϵ into that of E, into the sine of the angle between their directions. This also defines the prefix V before two vectors. The + direction is defined thus. Let ϵ and E be the short and the long hands of a watch. Let ϵ point to XII. and E anywhere else. The angle between ϵ and E is measured positive in the usual direction of motion of the hands, and the direction of $V\epsilon E$ when positive is from the face to the back.

It is possible, consistent with the linear principle, for k_1, k_2, k_3 to be all zero, and ϵ not zero. Then

$$C = V\epsilon E$$

simply; the current is always perpendicular to the force, of maximum strength when ϵ and E are perpendicular, and vanishing when they are parallel.

Returning to equation (1). Multiply by E. Then

$$EC = Ek E = Q \text{ say}, \quad . \quad . \quad \text{(Dissipativity)} \quad . \quad . \quad . \quad (4)$$

Q is the dissipativity per unit volume. It is in the first place the rate of working of the force E, and next, by the experimental law of Joule, the rate of generation of heat per unit volume. (4) is a scalar equation. All our equations will be either wholly scalar or wholly vector. In case of isotropy, with k a scalar constant, we may write $Q = kE^2$; or, since $E = k^{-1}C$, $Q = k^{-1}C^2$, where k^{-1} is the specific resistance, a more familiar form of Joule's law. But in general, when k is a linear vector operator, we must not take $Ek E = kE^2$, unless E act parallel to one of the principal axes, when we may do so, with the appropriate value of k for that axis. When E and C are not parallel, the product EC means the strength of E multiplied by that of C, and by the cosine of the angle between their directions, which of course includes the common algebraic meaning of EC, since when E and C *are* parallel, $\cos 0^\circ = 1$. Referred to three rectangular axes, if E_1, E_2, E_3 are the compounds of E, and C_1, C_2, C_3 those of C, then

$$EC = E_1C_1 + E_2C_2 + E_3C_3 \text{ (Scalar product)} \quad . \quad (5)$$

which is an equivalent definition of EC.

Coming next to specific capacity, although there are media, as air, which appear to have no conductivity, yet, by the continuity of the electric current, they can support current; not steady, but transient, and stopped elastically. By an obvious mechanical analogy the integral current is termed the electric displacement. Let this be D, and let E, as before, be the electric force. We have then

$$D = \frac{1}{4\pi} cE \text{ (Electric displacement)}. \quad . \quad . \quad (6)$$

The excrescence 4π is a mere question of units, and need not be discussed here. The 4π's are particularly obnoxious and misleading in the theory of magnetism. Privately I use units which get rid of them completely, and then, for publication, liberally season with 4π's to suit the taste of B.A. unit-fed readers. Of course, if it comes to numerical comparisons we should have to consider the ratios of units in the ordinary to what I may call the rational system. Sometimes it is $\sqrt{4\pi}$, sometimes $(4\pi)^{-\frac{1}{2}}$, sometimes 4π, sometimes unity, but in the mere algebra it is simply a matter of putting in 4π's here and there in translating from rational to ordinary units.

In a dielectric medium, the force and the displacement are simultaneous, like the force and the current in a conductor. Time does not appear in the equations. In an isotropic dielectric, c is simply a scalar constant; in an eolotropic dielectric it is, as described above for k, a linear vector operator, with this difference however, that there is no rotatory vector ϵ, so that the relation of D to E is settled by the values of the principal capacities, and their axes.

Multiply (6) by $\frac{1}{2}$E; then

$$\tfrac{1}{2}ED = \frac{1}{8\pi} EcE = U, \text{ say.} \quad \text{(Static energy)} \quad . \quad . \quad (7)$$

U is the electrostatic energy per unit volume, the work done by the force on the displacements as they rise from 0 to their final values, or the final displacement multiplied by the mean force which produced it. This energy is stored, and is recoverable in work like the energy of a perfectly elastic strained spring. It is unnecessary to assume that there is any real displacement of anything in the direction of the electric displacement. All the electric and magnetic quantities are more or less abstractions, measurable abstractions, whose real signification is as yet unknown.

Far less is known of c than of k, and it is not so agreeably definite as k. Solid dielectrics appear to have imperfect electric elasticity, as they have imperfect mechanical elasticity. The bent spring, with the applied force removed, and brought quietly to rest, is not exactly in its equilibrium position. A small part of the displacement remains, and slowly disappears. This is easily shown when not visible to the eye by using a microphonic contact; though, by the way, the variability of the contact itself makes it a bad method. Most likely there is no such thing as a perfect return even with small displacements; we cannot draw a hard and fast line to mark the limit of perfect elasticity.

All non-conductors are dielectric. Bad conductors are also dielectric. Good conductors, even the best, may be dielectric as well, so that with a force E we shall have a conduction current kE and a displacement $(4\pi)^{-1}c$E co-existing. But in such case, as well as in the case of known dielectric power of bad conductors, kE is not the complete or true current, unless the displacement remains steady. The time variation of the displacement is itself an electric current, and the true current is the sum of the conduction current and of the rate of increase of the displacement. Let Γ be the true current, we have, in a conducting dielectric, or dielectric conductor,

$$C = kE, \qquad D = \frac{1}{4\pi} cE,$$

$$\Gamma = C + \dot{D} = kE + \frac{1}{4\pi} cE, \quad . \quad . \quad . \quad \text{(True current)}. \quad . \quad (8).$$

Put $c = 0$ in a pure conductor, and $k = 0$ in a pure dielectric. It is the true current that is 'the current" when we come to induction and variable states.

In the equation $\Gamma = C + \dot{D}$ we have three vectors. They form the three sides of a triangle, unless $\dot{D}$ should be parallel to C. But $\dot{D}$ may not be parallel to C, nor need it be parallel to D. If we charge a condenser formed of two large flat opposed conductors very close together, the displacement current, when setting up the displacement, is, by general reasoning, parallel to the displacement—at least away from the edges. But this is not invariable. When charged conductors are discharged, the displacement current does not in general follow the tubes of displacement. To do so would require instantaneous propagation of the disturbance to infinite distances. The displacement current may be perpendicular to the displacement—viz., when the displacement at a certain place changes its direction without changing in amount.

Digitized by Google

Multiply (8) by E; then

$$E\Gamma = Ek E + \frac{1}{4\pi} Ec\dot{E} = Q + \dot{U} \quad . \quad . \quad . \quad . \quad (9).$$

The rate of working of the force is accounted for partly in heating (Q per second), and partly in the increase in the energy U of the displacement. (Equations (4) and (7)). The first is lost from the system, the latter is stored.

Whilst conductivity depends on the presence of matter, the existence of capacity is independent of matter, though modified in amount by its presence. That is, capacity is a function of the ether, which is the standard dielectric medium of least capacity. Ether is a very wonderful thing. It may exist only in the imaginations of the wise, being invented and endowed with properties to suit their hypotheses; but we cannot do without it. How is energy to be transmitted through space without a medium? Yet, on the other hand, gravity appears to be independent of time. Perhaps this is an illusion. But admitting the ether to propagate gravity instantaneously, it must have wonderful properties, unlike anything we know. Similarly in the propagation of the transverse vibrations of light, it is not easy to conceive ether acting as an elastic solid. We may know some day. But if not, what matter? Things will go on all the same whether we know how it is done or not. What vanity is this the philosophers are striving after? Is it not "Science, falsely so called," when there is the infinite blank of the Unknowable behind? And, speaking of blanks, might there not be a great blank in space, to which we shall arrive some day, to find all theories confuted?

Coming next to permeability, all bodies sustain magnetic induction, and most of them to nearly the same degree. H being the magnetic force, B the induction, and μ the permeability,

$$B = \mu H \quad . \quad . \text{ (Magnetic Induction) } . \quad . \quad (10).$$

μ is taken as unity in ether (in the electromagnetic system), and is either a little greater or a little less in most bodies. But in some bodies it, very singularly, runs up to large numbers. Iron is the principal offender; then come nickel and cobalt, minor magnetics, but far removed from the crowd of almost unmagnetisable substances. Fe = 56, Ni and Co about 58·5. What can it be?

The linear connection between H and B is very unsatisfactory. Not merely does μ vary with the temperature, and enormously from one piece of iron to another, being, with moderate strength of magnetic force largest in the softest iron and smallest in hard steel, but it varies with the magnetic force, first increasing with the force, and then, more importantly, decreasing greatly; how far down is unknown. To make matters worse, part of the induction produced by applied magnetising force becomes fixed, for the time, remaining after the removal of the force. Thus the linear connection between H and B must be taken with salt. But within moderate limits, and excluding permanent magnetisation, which requires separate consideration, μ in equation (10) may be taken to be, like k and c before, a scalar constant in case of isotropy, and a linear vector operator in eolotropic media, being then, like c, self-conjugate, or without the rotatory power.

μ in soft iron is said to run up to 5,000 or 10,000 (Rowland's experiments. I forget the exact figures). But in general it is very far lower than these tremendous figures. From experiments on the retardations of coils made some years ago, including straight solenoids, I concluded that μ = from 50 to 200 was safe.

Not B, but $B/4\pi$ should be the magnetic induction to compare with D, the electric induction, or displacement. So, dividing (11) by 4π, and then multiplying by $\frac{1}{2}H$, we have

$$\tfrac{1}{2}H\frac{B}{4\pi} = \frac{1}{8\pi}H\mu H = T, \text{ say, } . \text{ (Magnetic energy) } . \quad (11).$$

T is the energy of the magnetic induction per unit volume, when wholly induced, and acting conservatively.

(TO BE CONTINUED.)

CORRESPONDENCE.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The remarks of Professor Dolbear, quoted p. 125, are no doubt an interesting attempt to elucidate a very important matter, but some portion of them really appears to be very wide of the mark. I refer to the effects attributed to the discharge from a Holtz machine, which is estimated to produce through a wire a current of 50 million amperes, which is supposed to produce no apparent effect, because its duration is probably less than one millionth of a second. I think both the estimate and the explanation are erroneous. The power of a current to destroy a wire is not limited to the calculated energy carried by the current. We cannot say that the wire could not be vaporised or melted unless that energy represented the heat needed for those results. The molecular motions involved in the passage of the current may disintegrate the metal and reduce it to its ultimate molecules, even though the heat equivalent were far below that required to fuse the metal; in fact, a metal carrying a current and fused by it does melt at a point considerably below its temperature of fusion, when this is a consequence of heat. Of course this is assuming the possibility of a large current passing for an infinitesimal period without the energy corresponding to it under ordinary conditions, an assumption we have no right to make. But Professor Dolbear's actual figures bring out a very different result, for 50 million amperes with an E.M.F. of 50,000 volts for, say, 1 millionth of a second is $\frac{5\cdot\times10^7\times5\times10^4}{1\cdot\times10^6} = 25\times10^5$, or two and a half million joules. This amount of energy would cause a large conductor to vanish away, and its conversion would require a Holtz machine of somewhat unusual dimensions.

But what is the current we might look for from a Holtz machine, or rather from its discharge? Say its potential E is, as stated, 50,000 volts, and the resistance of the wire ohm ·001, is it proper to employ Ohm's formula to estimate the resulting current? Is $\frac{50{,}000}{\cdot001} = 50{,}000{,}000$ a correct consequence of the conditions? Professor Dolbear has neglected the very caution he gives as to the need for considering quantity as well as E.M.F. We know that a Holtz machine gives only an infinitesimal current, because its own internal resistance is so vast. Therefore the conditions considered involve the discharge of an accumulation, as in a spark; and it is necessary to take into account not only the potential of the discharge and the resistance it is to traverse, but also the *quantity available to pass as a current*. If we neglect this we must take into account not only the resistance of the conductor, but also that of the machine, or the condenser holding the charge, and then we get among the megohms, which will vastly reduce the Professor's result.

The actual quantity in such a discharge is probably not easy to ascertain, but a very rough calculation will serve the purpose. Taking the electrostatic system, we may consider that the balls of the conductor have unit capacity, that of a sphere of one centimetre radius, and then if we take 60,000 volts (to save fractions and 3×10^{10}) as the ratio of r, we find that the quantity is about two-millionths of a coulomb. Now, if we take the period of discharge at the highest estimated, viz., one-millionth of a second, and suppose the current uniform, we have a current of 2 amperes instead of 50 millions. Or if we consider that the capacity of the whole system of balls and jars is one microfarad, then with an E.M.F. of 50,000 volts we get only one thousandth of the current stated. The Holtz machines have generally but a very small fraction of a microfarad capacity, so that we come to something like the first result, viz., that the amperes of current so produced must be reckoned by units, and probably far below one ampere instead of by millions.

The calculations as to the current and energy which may traverse the human body are subject to similar corrections of errors caused by the slavish use of Ohm's formulæ without considering the natural parts. The resistance from hand to

Digitized by Google

hand of the human body ranges under ordinary conditions from 5,000 to 10,000 ohms, but this is when measured with small battery power and when grasping good conducting handles. This is entirely different from the accidental contact of a small surface, and that probably at only one point instead of two. It is of little use to reckon up possible amperes of current and consequent horse-powers traversing the body under conditions so entirely different. Then, also, the resistance of the body, with other conditions alike, would not be the same with currents of milli-amperes as usual, and of several amperes as estimated. We know from Edison's motograph that great changes instantly result from the generation of gases. Now the instant effect of the commencement of a large current would be the production of an external film of gas, and a superficially changed surface, due to the action of nascent acids and alkalies in the skin. There is no likelihood of the generation of gases within the body.

The real danger would appear to have little to do with such calculations of current; it is due to a physiological effect of the static actions which accompany the setting up of the difference of electric potential; it is the sudden and violent contraction which occurs in all the muscles traversed, and the nervous derangement due either directly to the molecular motion set up in the matter of the nerves in the setting up of electric stress, or else indirectly to the effect of pain and fear, or, in the usual phrase, nervous shock. This is why our electromotive force, which is absolutely harmless when sustained and producing current, may be dangerous and even fatal in the alternating form which repeats shock after shock, and, by setting up rapid molecular motions in the organism, destroys its proper vital action. This indicates the importance of perfect insulation, and such separation of conductors as to avoid risk of getting the body into the circuit.—Yours, &c.,

J. T. SPRAGUE.

THE ELECTRIC LIGHTING ACT COMMITTEE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the letter from Mr. H. F. Jool, which appears in your last issue, may I be permitted to point out that the premises upon which that gentleman bases his arguments can scarcely be considered as being in accordance with the facts. From Mr. Joel's statements it is to be inferred that the committee of which Lord Thurlow is chairman is controlled by the Anglo-American Brush Electric Light Corporation and the Edison and Swan United Electric Light Company, and that all the members of the Executive "belong to, or are connected with, one or the other of the two companies before mentioned," and that "in its present form the Executive Committee only speaks for the two companies, and only represents company interests." How far this statement is correct can be determined by reference to the list of members of this committee, which has already appeared in extenso in *The Electrician*, and from which it will be seen that the committee consists at present of 45 members, of whom only 13 are, so far as I know, either directly or indirectly connected with the two above-mentioned companies; that, out of about 20 English electric lighting companies to be found in the Directory, about 15 are represented on the committee; that several private electric lighting firms (like Messrs. Crompton) are represented; and that among the members are one of the vice-presidents of the Institution of Civil Engineers, one of the vice-presidents of the Society of Telegraph-Engineers and Electricians, and many of the foremost scientific and legal authorities upon the subject of electric lighting legislation. The Executive Committee was appointed from the full list of members by ballot at a representative meeting of this committee, and consists of ten members, two of whom are associated with the Anglo-American Brush Corporation, two with the Edison and Swan Company, one with the Hammond Company, and one with the Electrical Power Storage Company, the four remaining members being Sir Frederick Bramwell, Mr. R. Campbell, Mr. R. E. Crompton, and Captain Douglas Galton, C.B.

I merely wish to add that the formation of this general committee is only one more step in the progress which a combination of electric lighting companies and others had already made in the direction of reform in the interests of the industry generally, and is the immediate result of the interview which they had with the President of the Board of Trade a few weeks back. This committee has already, therefore (apart from its influential and representative character), a *locus standi* which will add weight to its deliberations, and doubtless secure for its decision the especial consideration of the Board of Trade.—Yours, &c.,

C. GARCKE,
Hon. Sec. to the Committee.

Belvedere road, Lambeth, London, 31st Dec., 1884.

HEATING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of last week mention is made of experiments carried on in France for heating railway carriages with electricity. Heating by electricity has not as yet attracted the attention which so important a subject would seem to merit, and it may, therefore, interest your readers to know that since October, 1883, I have successfully warmed some of the smaller rooms of my house with a very simple apparatus, as described in my patent, "Electrical Heating," No. 4961, 1883 (some of the forms of which are specially designed for railway carriage warming). In heating rooms by this means there is the great additional advantage that a current of fresh air from the exterior can be passed through the electrical heater, so as to enter the room at any desired temperature within moderate limits. The outside air being, say, at freezing point, can enter the room fresh and pure at a temperature of 200deg., causing thorough ventilation, a matter of no small importance for sick rooms or hospitals. A modified form is used nightly in my house as a bed warmer, the heat being turned on or off at the bedside at any required moment, a great convenience for invalids. As a minor use I also employ the same principle for a chicken incubator, and it is especially applicable to the French system of "thermostatic" nursing, avoiding the noxious fumes of the gas or oil at present employed.

An ordinary foot warmer for railway carriages is a very simple adaptation of the same principle, but if desired, fresh warmed air can be admitted, and the temperature of any closed carriage be regulated by the form used for chamber heating. When once the electric current is furnished to railway carriages for lighting purposes, which cannot be long delayed, this will doubtless prove to be a very convenient and cheap method for heating them. If the arrangement is fitted to permanent receptacles containing salts, such as acetate of soda, the heating of carriages can be carried out with still greater facility and convenience, and at a very low cost.

I shall be happy at any convenient occasion to show you some forms of the apparatus at work.

With the further exception of the system patented by Mr. Oswald Rose, in May, 1882, I have no knowledge of any other attempt to deal practically with the subject.—Yours, &c.,

JOHN S. SELLON.

The Hall, Sydenham, Dec. 30, 1884.

FLUORESCENCE OR PHOSPHORESCENCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is well known that fluorescence or phosphorescence is common to a great many substances, viz., certain varieties of fluor spar, glass coloured by peroxide of uranium, red seaweed of different kinds, &c., but the cause of this phenomenon is still a matter of doubt to many. It is believed by Professor Stokes that the explanation of fluorescence lies in the communication of motion by means of the intermolecular forces, from the molecules or part of a molecule thrown into agitation by the vibrating ether, to the neighbouring parts, and thence to the mass in general.

The following experiment appears to agree with the above explanation of Professor Stokes:—By holding a partially exhausted incandescent lamp in one hand and rubbing it with

Digitized by Google

the other until it becomes warm, beautiful phosphorescent effects may be produced. Of course, these effects are best seen if the experiment be performed in a dark room. After being rubbed, if the lamp be tapped by the finger fluorescent effects will be produced almost as bright as in the former case. The friction thus produced by rubbing and the vibration by tapping appear to be the cause of fluorescence in this case. If the vacuum be either very good or very bad these effects will be produced with difficulty; if the vacuum be entirely destroyed, no effects will be observable.

We may conclude from the foregoing that the vacuum of incandescent lamps may be roughly tested in this manner.—Yours, &c., JOHN B. DUNCAN.

16, Brandling-place, Newcastle-on-Tyne, Dec. 22, 1884.

SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On December 20th you published an article on the electrical tram car recently built by the Storage Company, in which you gave certain figures as to the depreciation of the cells which are likely to be misleading.

You say that owing to a new design lately introduced the useful output for a given weight has been increased without in any way sacrificing the *durability;* and later, that Mr. Reckenzaun has based his figures for working cost on a depreciation of 50 per cent. as a safe limit. This would naturally imply that the cells used for lighting purposes would depreciate in the same ratio, which is far from being the case.

The type of plate manufactured by the Storage Company enables the conductor and the active material to be disposed to the best advantage, but the proportions are varied according to requirements.

The accumulators supplied for lighting purposes are made with a view to obtaining great durability coupled with a high effective return, whereas in the tram car cells the first consideration is a rapid discharge from a minimum weight.

In the latter case the metal is distributed where most needed, but the same durability cannot be expected as with cells designed for lighting or other purposes where weight is of minor importance.

We have every reason to hope, however, that Mr. Reckenzaun's allowance for depreciation will be more than ample, as the cells which were first made have been in constant use for over three months, and show no signs of deterioration.

It is impossible to say definitely what the life will be of the plates manufactured for lighting purposes with the latest improvements, but it may be mentioned that even with the older types the positives frequently lasted 18 months, and there is little doubt that this will be exceeded with the plates now being supplied.

The depreciation is confined almost entirely to the positives, and the company have already made arrangements to meet their customers in this respect by quoting a special price for renewal plates.—Yours, &c.,

BERNARD DRAKE,
Managing Engineer, Electrical Power Storage Company.

FUSIBLE OR AUTOMATIC CUT-OUTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read the description of Mr. Cunynghame's ingenious automatic cut-out, and noticed your remarks on the failure of Messrs. Woodhouse and Rawson's fusible cut-outs, may I be allowed to say a few words on this subject? It is stated that "fusible cut-outs are objectionable," firstly, because of "loss of power and change of melting point through heating." Is not this paradoxical? for the reason that loss of power means increased resistance; while on the contrary it is the lowered resistance, produced by the deterioration of the alloy, which causes the fuse to go at a lower temperature. The second objection is, that "it is impossible to test each plug, and often considerable variation is found." This I can account for if the arrangement was as described—namely, "foil fastened on fibre." How can it be otherwise, as there are two opposing forces, the expansion of the foil, due to the rise in temperature, resisted by non-expanding vulcanised fibre? My experience is, that if the foils are clamped at their two ends only, and allowed to expand freely all along their length, not only are they absolutely reliable, but the current at which a number fuse will not vary more than 2 per cent.; and if the material employed is suitable no change of melting point will be noticed. The automatic cut-out has its uses, but as a rule, if untouched for a length of time, is generally found to stick so that it will not pull; besides, what is there to prevent the man in charge of an installation from increasing the current by manipulating the instrument, and thus shorten the life of the lamps?

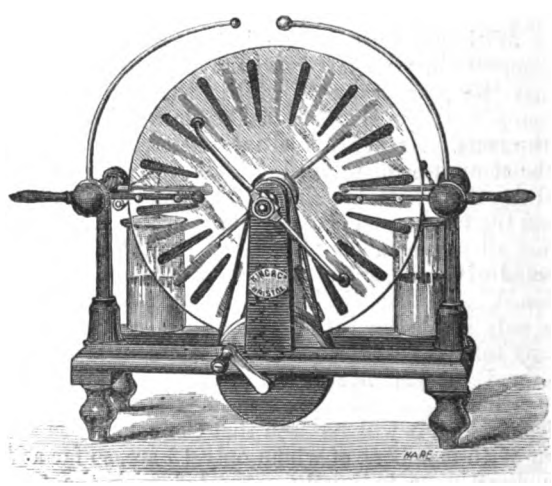
I do not think the increased resistance of fusible cut-outs when heated would be found of any great importance, and certainly not more than the resistance of the coil of the electro-magnet, and that of the copper legs in the mercury cup after they have been in use some time and become dirty. As to the risk of employing mercury in an apparatus where there is just a chance of an arc being formed I will say nothing, but only state that I should decline to sleep in a room where the electric circuits were protected by an instrument which might possibly cause similar disastrous consequences to those which were fatal to the inventor of the mercurial electric light.—Yours, &c., KILLINGWORTH HEDGES.

25, Queen Anne's-gate, S.W.

THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent Colonel Knipe has directed attention to what he calls a "grave error" in the description of the Wimshurst machine given in our new catalogue, which you were good enough to notice in your issue of the 13th inst.



The supposed error at once vanishes when it is understood that the *wire brushes* which we state collect electricity from the plates are not those wire brushes at the extremities of the curved rods which, as your correspondent truly observes, "only put two opposite strips of brass on the same diameter in electrical connection;" but the brushes to which we refer are those which we fit on the forked conductors, or collecting combs, to which the movable electrodes are attached.

We have found that if, in addition to the spikes on the collecting combs, wire brushes be fixed, the machine is rendered more efficient.

This arrangement constitutes one of several improvements we have made in these machines.

The position of the curved rods is shown in the accompanying illustration, which also shows the general arrangement of conductors, electrodes, &c. It was not our intention when compiling our catalogue to give a *full* account of the way in which electricity is generated in these remarkable machines,

Digitized by Google

for we have already done this in a circular, which may be obtained from us on application.—Yours, &c.,

KING, MENDHAM AND CO.

Western Electrical Works, Bristol,
December 29, 1884.

BERTHOUD-BOREL CABLE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of 29th November you mention the gutta percha covered cables which have been laid down in the Arlberg Tunnel. In addition to these seven miles of our No. 25 Berthoud-Borel cable were laid, consisting of three conductors, each of 7 strands of No. 22 B.W.G. After the laying of our cable it was tested and found to have an insulation of 7,000 to 8,000 megohms per kilometre for each conductor. The cable was delivered in lengths of 1,000 metres, so that there were 10 joints. Tests were made after the jointing and laying of each length, and it was found that the insulation per kilometre remained the same after each joint. Since then a further order has been received from the Austrian Government for six and a quarter miles of our No. 3 cable, consisting of one conductor of 7 strands of half a millimetre diameter. This particular cable is largely used by the French Ministry of War.

With regard to our cables now being laid under the Greenock Provisional Order, it may interest you to know the results of the insulation tests made on the cables before leaving the factory. It was specified that the cables should have an insulation resistance of not less than 1,000 megohms per mile at ordinary temperature. The actual results obtained when tested under water were:—

1,925 metres of cable of one strand of 1·2 millimetre diameter, 25,000 megohms per kilometre.
457 metres of cable of 36 strands of 1·5 millimetre diameter, 6,500 megohms per kilometre.
465 metres of cable of 36 strands of 1·5 millimetre diameter, 6,800 megohms per kilometre.
582 metres of cable of 12 strands of 1·6 millimetre diameter, 12,500 megohms per kilometre.
584 metres of cable of 12 strands of 1·6 millimetre diameter, 12,500 megohms per kilometre.

The insulation given is therefore from 3½ to 15½ times better than what was asked for.—Yours, &c.,

H. BOISSELIER,
For the Kinetic Engineering Company.

London, Dec. 30, 1884.

A BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can you or any of your correspondents tell me how to make up a battery (not Grove or Bunsen) that will run an incandescent 2½ candle-power lamp for six or seven hours *full power*?—Yours, &c.,

H. ANDREWS.

7, Newark-street, Reading, December 29, 1884.

PAYING FOR SPECIFICATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having read the recent correspondence published in *The Electrician* upon this subject, kindly permit us to state that it has been in no way an innovation on the part of Messrs. Mackenzie and Brougham charging for the specifications and drawings in connection with the Grosvenor Gallery electric lighting contract, so far as the engineering portion of the work is concerned, in substantiation of which we beg to enclose you various cuttings from *The Engineer* and *Engineering*, inviting tenders from some of the leading public companies and engineers, in every instance of which a charge is made for the specifications and drawings, and in no case is it stated that the fee will be returned, but in several cases you will perceive it is distinctly mentioned that the fee will *not* be refunded.

We send you this communication as we consider from our experience that the engineers in question were certainly only acting upon a usual precedent in the course they adopted.—Yours, &c.,

MARSHALL, SONS AND CO. (Limited).

Gainsborough, Dec. 23, 1884.

(For continuation of Correspondence on this subject see p. 165.)

ALCIDE LUDOVIC TERNANT.

It is with much regret that we have to announce the death at Marseilles on Saturday last, after a short illness, of Mr. Alcide Ludovic Ternant, manager of the Eastern Telegraph Company's establishment at Marseilles, at the age of fifty-two. The late Mr. Ternant was born in Arras (France) in 1832. The son of an inspector of public instruction, he was educated in the Lycées of Tours and Cahors, wherefrom, after taking his degrees, he was appointed as Professor to the Lycée of Moulins. He left, however, his professorship to join the French telegraph service in 1853, and taking a special interest in submarine telegraphy, he sought and obtained a situation in the service of the Mediterranean Telegraph Company. He was sent from there to Cagliari in connection with the first cables laid from there to Bona and Malta. After a few years spent in the Persian Gulf Mr. Ternant came to England, where he devoted himself to the study of cable testing and engineering at Silvertown and Woolwich. He was for some years Mr. Henley's electrician, and in that capacity took part in several cable expeditions. In 1870 he joined the Eastern Telegraph Company as their manager and electrician at Marseilles, where till his decease he had been acting as the company's representative. Although a staunch Frenchman, Mr. Ternant was considered as thoroughly Anglicised in the telegraph service, and had done much to benefit his country by introducing English practice in French telegraphy. The telegraphic international service requires men of his stamp, and in this respect it may be said that he was the right man in the right place. Locally Mr. Ternant gained the confidence and respect of his countrymen, who daily consulted him on the practical applications of electricity. He was lately elected president of the Société Scientifique Industrielle, and also of the Société de Statistique of Marseilles. Mr. Ternant was the first in France who studied in scientific papers the laws of the propagation of the electric current in submarine cables, and he had published several important papers on this subject in the *Journal des Télégraphes* and the *Annales Industrielles*. He had also published several interesting works on the telegraph and the telephone, which are consulted daily by those interested in these matters. His kindly and aimable disposition endeared him to all his friends and colleagues, who sincerely mourn his lamented death. His funeral took place at Marseilles on Monday, and his remains were followed to their last resting place by a large and influential number of friends, among others, Mr. Duportal, director of the French Government Telegraphs; Mr. Bebz, engineer of Government Telegraphs; Mr. Lawton, assistant superintendent, Eastern Telegraph Company, several representatives of the local scientific and financial societies, and many others.

ELECTRIC LIGHTING AT VIENNA.—It has been decided to light the Imperial Palace, the Court Opera House, and the Burg Theatre of Vienna by electricity. The palace will be illuminated with 5,000 lights, the Opera House with 4,000, and the Burg Theatre with 3,000. The system to be employed is the Turettini patent, and the contractors are the Vienna Gas Company. The new Parliament House and the University will, in all probability, also be lighted electrically.

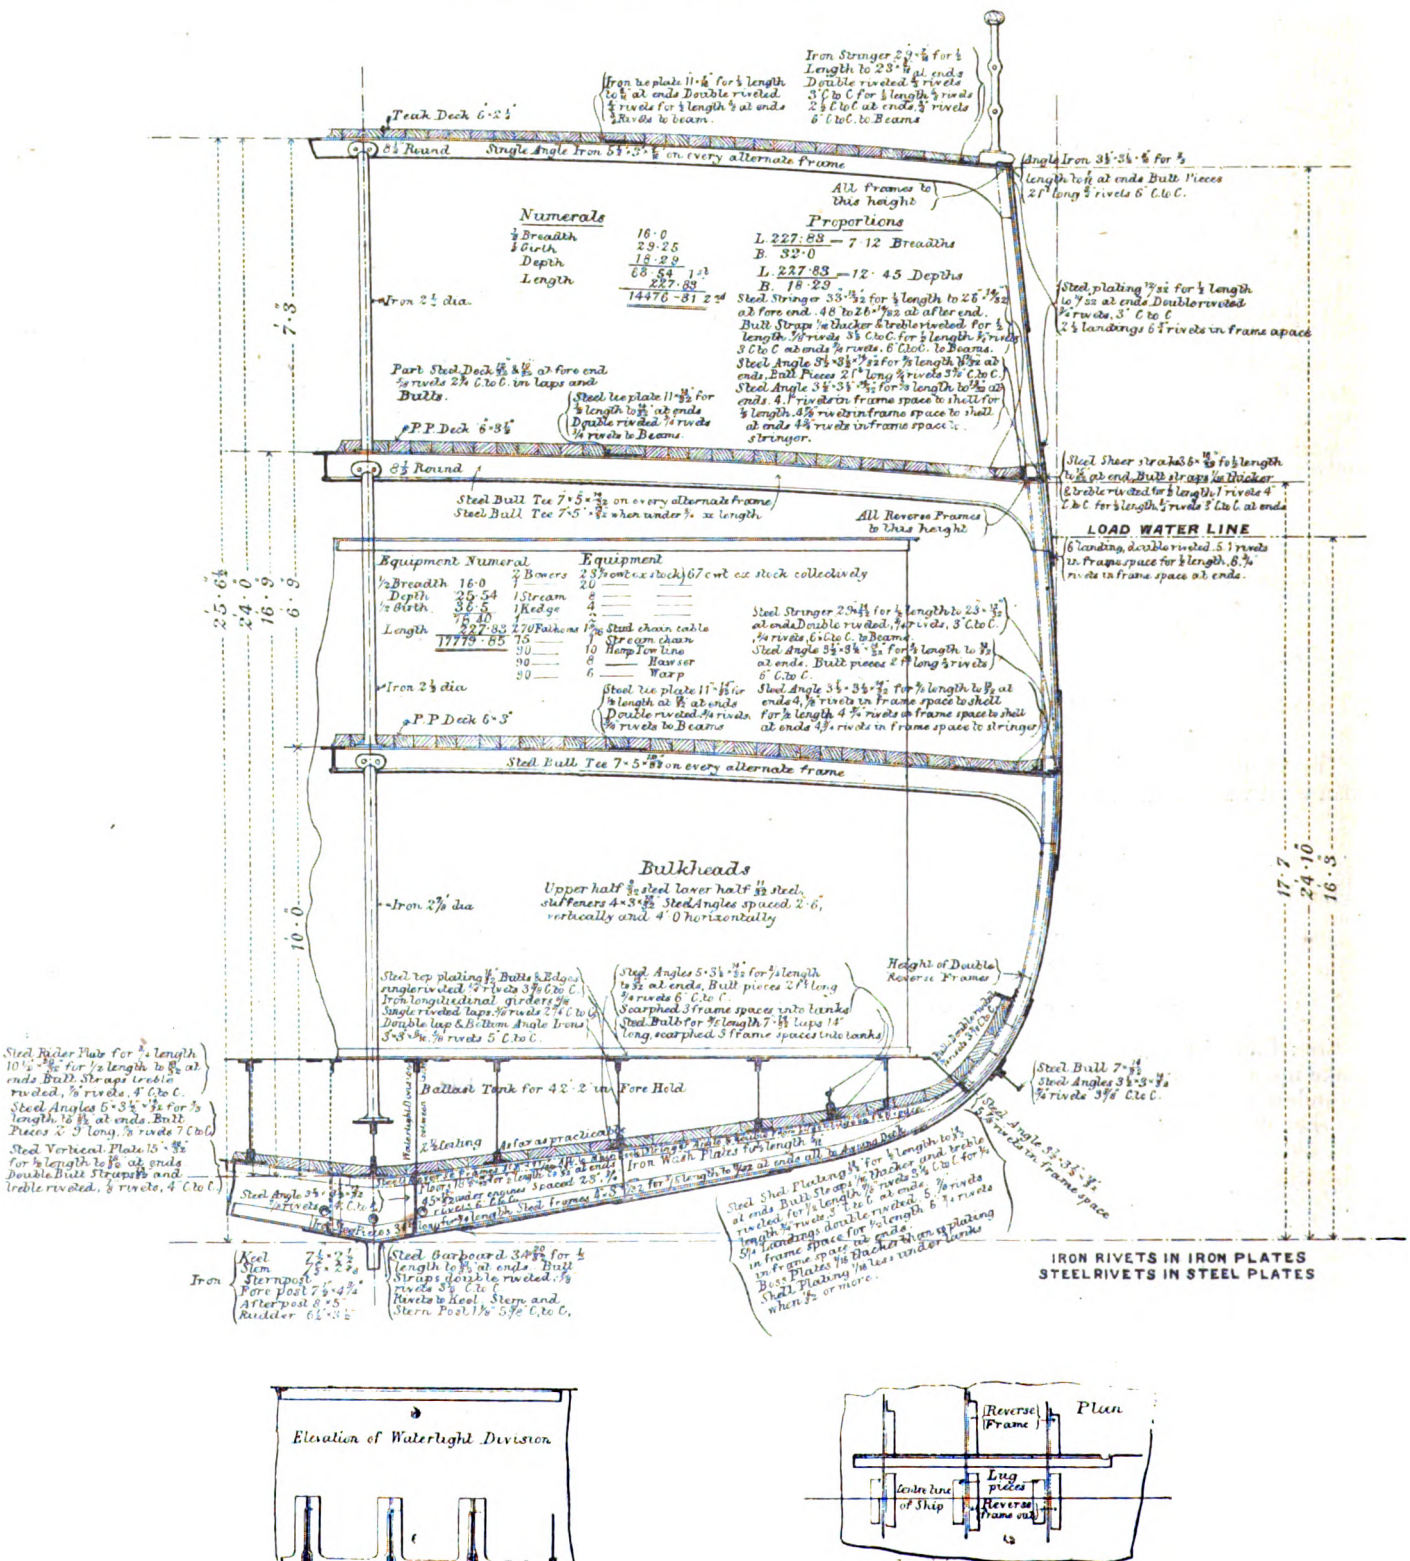
THE NEW CABLE STEAM-SHIP "THE MAGNETA."

Midship Section of a Steel Screw Steamer for Cable Purposes to Class 100 A. Awning Deck Special Survey

Dimensions

Length (between perpendiculars)	230'-0"	
Breadth (moulded	32'-0"	
Depth (do) to Main Deck	17'-7"	
Do (do) to Awning Deck	24'-10"	



Digitized by Google

In a note in a previous issue the launch of a new cable ship was recorded. We commence in this issue to give various details of the ship—details which, so far as we know, have never before been published. Ships have before now been specially built for cable work, but we do not hesitate to say that never before in the history of submarine telegraphy has so complete a specification been prepared for the building and fitting of cable ships as those prepared for the "Magneta" and a somewhat similar vessel the "Electra." The "Magneta" has been built and engined by Messrs. Napier, of Glasgow, to the order of the Eastern Extension, Australasia and China Telegraph Company, from the design of Mr. Joseph Birnie. The ship, as soon as ready, will be sent to the Singapore station, and is therefore fitted for work in a tropical climate. It is hardly necessary to dwell at length upon the engravings which are given in this issue, inasmuch as they almost explain themselves. Before entering upon the description of the vessel we must congratulate the cable world, and the share holders of the Eastern Extension Company in particular, upon the acquisition of so fine an addition to their fleet. We have often said that submarine telegraphy is of modern growth. It is the work of men who are still among us—working as earnestly, as laboriously as in the days of yore, encircling the world in a network of wire, laying hold of scientific discoveries and fashioning them into weapons to wield for the benefit of civilisation. Their experience has been called upon in the production of these ships, with the result of obtaining an almost perfect equipment for the work.

The "Magneta" has the following dimensions:—	Ft.	in.
Length between perpendiculars	230	0
Beam	32	0
Depth of hold, top of floors to top of main deck beam	16	9
Depth, top of floors to top of awning deck	24	0

Tonnage (B.M.), about 1,096 tons.

The ship is intended to steam 11 knots while working on a consumption of 14 tons of coal per day, and carries coal for 16 days' steaming. She is of steel, the plates being rolled by the West Cumberland Steel and Iron Company. The position of the water ballast tanks will be seen from the drawings, as will that of the cable tanks, of which there are four. The tanks are similarly built, though not all the same size. It will be sufficient to describe one, say No. 2 tank, which is about 25ft. × 12ft., built on top of forward ballast tank. The top of water ballast tank is ½in. The plating is of steel of good quality, sides of tank ⅜in. in one length, plated vertically, with double-riveted external butt strips 9in. × 7/16in., with vertical joints planed, and all riveting perfectly flush inside. This tank is fitted with a cone, flush-plated, tapering from 6ft. to 3ft., with plate top. The bottom angles on top of water ballast tank are 3½in. × 2½in. × ½in. The top angles are double, 3in. × 3in. × 7/16in. inside and outside of tank to receive the feet of pillars from girders under deck to top of tank. The inside angles have eye-bolts about 8ft. apart for life lines, and recessed foot pockets for ascending and descending. The after-tanks, Nos. 3 and 4, have bottoms ½in., sides ⅜in., and strips 7/16in., angles like No. 2.

The main deck is plated with steel fore and aft, according to Lloyd's rules, covered by a 3in. × 6in. teak deck, in long lengths, fastened with galvanised bolts and nuts, and finished in the usual manner.

The fresh water tanks are in the fore hold, and the vessel carries two of Starnes and Sons' cylinder condensers, capable of condensing 5,000 gallons per day. The improved steam stearing gear of Davis and Co. is adopted. The fore and main masts are of steel, with wooden telescopic topmasts. A continuous line of railings is carried round the ship, the entire length of which is also fitted with awning stanchions of galvanised iron 8ft. apart, with galvanised plates on rails and sockets on waterway. The awning has support centrally on pillars of galvanised iron, with ridge lines of galvanised wire and boxes of yellow pine. This is not a luxury, but, with side curtains, a necessity in tropical climes. The ship carries six boats, two lifeboats, two cutters, captain's gig, and a dingy, fitted and hung in the most approved manner.

The ship is lighted partially by electricity, a special engine and dynamos being placed therefor upon a platform in the engine room. Incandescent lamps are fitted in the saloon, saloon cabins, steward's pantry, in the cabins of the officers, electricians, and engineers, in the chart, engine, dynamo, and testing rooms, in the cable tanks and along awning deck, while a powerful search light with reflector is on the bridge. The electric light, as well as the cable apparatus, has been supplied by Messrs. Johnson and Phillips, of Charlton, while all the electrical apparatus (of which more hereafter) is by Messrs. Elliott Brothers, of the Strand. The vessel is being fitted by Messrs. M'Whirter, Roberts and Co., with their system of exhaust ventilation by steam, as fitted to several other telegraph ships, by which means 1,000 cubic feet of air per minute is extracted by each ventilator.

Of course a well-fitted workshop is one of the first necessities on board a cable ship, and that of the "Magneta" will be found very perfect. The testing room is on awning deck in line with the wheel house, and is built of teak, and care has been taken in construction to avoid as much as possible vibration from the steam stearing gear, which would disturb the instruments. A steam winch is fitted on the main deck, and a steam sounding machine, fitted complete with sounding wire and leads by Messrs. Johnson and Phillips, is as near the taffrail as convenient. As we hope to illustrate the engines among other details of the vessel, we shall only now say they are 200 horse-power, of the compound surface condensing type, with inverted cylinders and direct acting. The boilers are of the cylindrical multitubular type, two in number, built entirely of the West Cumberland Steel and Iron Company's brand, with three furnaces to each. The furnaces are Fox's patent corrugated, the parts exposed to fire being of Lowmoor iron, the shell of steel. In addition there is a donkey boiler of the cylindrical multitubular type; tubes, 2½in. in diameter. Both main and donkey boilers are fitted with Galley's patent bars.

From these few details, it will be seen that the most modern improvements in every direction have been utilised in order to make the ship in every shape and form most competent for the work she has to do.

The cable gear is of the most modern design, and consists of bow guards and triple sheaves, davits, crosspiece and three tackles, stopper hooks and plummer blocks, dynamometers for both picking up and paying out over bows, to register very light and very heavy strains, with all lead wheels. Then we have a double combined picking up and paying out machine, with engines of special design, with holding back gear for paying out, and draw off gear for picking up. To insure rigidity and avoid pillars in between decks, fore and aft foundation plates are riveted to steel main deck with web plates, double angles top and bottom, with foundation plate and chocks fitted overhead between deck beams in way of holding down bolts.

The saloon is of wainscot oak, inlaid, French polished, with circular panels, gilded capitals, and edges of overhead mouldins gilded. All doors have handsome finger-plates. The hand-rails are of polished maple, with electro-plated brackets in saloon and corridor. The overhead of saloon is done in flatted white, picked with gold on edges of mouldings. The saloon, captain's, chief electrician's, chief engineer's, and assistant electrician's cabins are connected to steward's cabin by means of electricity. Saloon, pantry, closets, and baths have scuppers, all carefully trapped, leading down bilges into waste tank.

It is necessary to say a few words about our illustrations. It may be thought unfortunate that the midship section could not be given on a somewhat larger scale, as the information it contains is both unique and important; still we think that with a little care the whole of the information can be deciphered. The details in the sheer plan, the lower deck, main deck and shade deck plans are on a somewhat larger scale, and ought to be quite clear. With regard to the picture on page 156, our engraver has done his best from the drawings to give a fair representation of the vessel.

The cable department and the electrical department will be dealt with, more fully, and illustrated, in a future article.

Companies' Share List 170

1884.

Adieu delights, that lulled me asleep;
Adieu my dear, whose love I bought so dear;
Adieu my little lambs and loved sheep;
Adieu ye woods, that oft my witness were;
Adieu good HOBBINOL, that was so true,
Tell ROSALIND, COLIN bids her adieu.

Thus ends the "Shepherd's Calendar." Spenser had sung through every month of the year, and in the words we have quoted bids his adieu. In another fashion we have passed through a year, and now bid it adieu. We speak our farewell with a mixture of sadness and gladness. The sadness is natural. Co-workers are gone from our side, and the coming of a new year reminds us that the time is approaching when the workers of to-day will give place to other workers, and we feel constrained to ask the questions: Are we earnest enough in looking to the security of the foundation upon which our successors are to build? What *esprit de corps* exists among the electricians of England? Is it such as tends to redound to the glory of their country, the advancement of science, and honour to individuals; or is it such as thinks mainly of £ s. d.? Reader, does your answer make you sad or glad; or have you no care in the matter?

The gloom which settled upon the electric lighting industry seems to be passing away, and while activity may not be very pronounced, there exists a widespread feeling that the worst is over. The silver lining of the cloud is widening, and we trust it may soon take the place of the blackness which has so long obscured the outlook. This is a source of gratification. It may not be amiss here to refer to one of the causes—many are just now referring to it as *the* cause—which has proved a scapegoat upon which the vials of wrath have been poured from an indignant and interested body of men. The Electric Lighting Act is now the proverbial red rag, and when mentioned before electrical engineers is sure to arouse their anger. At this juncture, then, we may be pardoned for affirming our consistent attitude as regards the question. We cannot refer to the criticisms of any other technical paper, because such criticisms do not exist. On June 10, 1882, referring to the report of the committee, and more especially to Clauses 8 and 10 of that report, we said "Both are impolitic, for the one will unnecessarily exasperate the gas interests, and the other will not encourage electric enterprise." On July 29th, 1882, on the passing of the Bill we said:—"The compromise entered into as regards the term of years was, like all compromises, not particularly satisfactory to either party; and it must not be assumed because 'all the leading companies with one exception' agreed to it that therefore they approved of it. On this, as on several other points, it was plainly a case of that or nothing." One other quotation from the same volume. On October 28th, 1882, we said:—"What we prefer to see is the electric light promoted by substantial and competent people, who will do a legitimate business in a thoroughly workmanlike manner." With these and many similar utterances, we cannot be taunted with not having considered the question; and when we now say—and say most emphatically—that the Electric Lighting Act has proved a blessing and not a curse, we may perhaps command attention.

At the time the Electric Lighting Act was suggested, the electric lighting enterprise was chiefly in the hands of speculators, promoters, and company mongers. It is in such hands now to a far greater extent than is good for it; but many of these parasites have been strangled off. There are still some left hanging on; but we have to thank the Electric Lighting Act for having swept away the worst of them, and also for having taught us that wisdom is not the growth of a night. Where was the experience in these companies? The answer is simple. Experience there was none. Experience has been gained at the expense of shareholders. We can point to it now; but the wisdom of to-day says ignorance in electric lighting matters was "intense" in those days. And yet it was into these ignorant hands that the future industry was to be given. The Electric Lighting Act was a blessing in disguise, and we are not so sure that we are even yet endowed with the necessary experience and foresight to enable us to draft satisfactory clauses to such an Act. The Act, to be of real service, should have certain clauses repealed and others inserted that will permit the industry with the least inconvenience to "drift" onwards. The electric light is at this moment a luxury. Then let it spread as a luxury; let it become fashionable; let it permeate and take root among those who can afford to pay for it, extending gradually but surely. Some of our electric light engineers could light a house; some could light a ship; but we doubt if there is one that can light a town—that is, light a town with the same certainty that a gas company can—giving a horrible light, nasty, disagreeable, dangerous, but commercially profitable. Putting aside Mr. Crompton, who, perhaps, has no compeer in electric lighting experience, it is to such men as Esson, Howard, Kapp,

Digitized by Google

Mordey, Sayers, Sellon, Wright, &c., that we have to look for carrying on the work to greater success. These men, with dozens of their colleagues daily conversant with the practice, have the inestimable advantage of the investigations of Professor Sir W. Thomson, Professor Garnett, Professor Lodge, Professor Thompson, and others, who are laboriously delving into the laws which regulate the practical work. It is marvellous how keenly the practical watches the theoretical, and the theoretical the practical. No sooner is a new experiment devised and certified in the laboratory than it is tried in the workshop; and, on the other hand, the investigation into the why and the wherefore of all practical work is searching and unremittent. The unknown, like the infinite, is as vast as our conception, and the words of Tiberius Cavallo, F.R.S., written more than a hundred years ago, are as applicable as if they were written yesterday. The last paragraph of his introduction to "A Complete Treatise on Electricity," second edition, 1782, reads as follows:—"Since the time of this discovery,* the prodigious number of electricians' experiments and new facts that have been daily produced from every corner of Europe, and other parts of the world, is almost incredible. Discoveries crowded upon discoveries; improvements upon improvements; and the science ever since that time went on with so rapid a course, and is now spreading so amazingly fast, that it seems as if the subject would be soon exhausted, and electricians arrive at an end of their researches. But, however, the *ne plus ultra* is, in all probability, as yet at a great distance, and the young electrician has a vast field before him, highly deserving his attention, and promising further discoveries, perhaps equally or more important than those already made." We look upon Cavallo's knowledge as dry bones compared with our own. Yet we can imagine a writer of a century hence asking whether the students of 1884 really understood the veriest rudiments of the subject. Cavallo's words should act as an incentive to all who feel interested in the science, should lead to hard work, though the student ought never to forget to go back before looking forward. The making of oneself acquainted with what has been done is the best method of preparing to plunge into the vast labyrinth of work to be done; and, above all, when about to start on the forward path be sure to determine well at what you aim. Desultory experiment is one of the curses of the age. The hope of stumbling accidently upon the philosopher's stone has been, and is, the source of more trials and privations than the breaking of stones upon the Queen's highway.

We have rather wandered away from our subject in giving advice to students, but we now return to consider another cause which operates somewhat against confidence in electric lighting and is a bar to progress. A kind and valued correspondent, whose experience is great, although more Continental than English, has put the case so forcibly, aptly, and clearly that we are fain to use his words. Readers will pardon the departure from elegance of expression, and admit its forcibleness:—"You wish my opinion upon the present and future position of the electric light industry. Well, here it is. We are at present on the eve of a new epoch. Electric light shall always go blooming on, but the question is with what rapidity? What are the obstacles that prevent it from rushing forwards and spreading itself everywhere according to the expectations expressed at its birth a few years ago? One of these obstacles is that within the last few years an innumerable number of 'petite' companies have arisen; they have sprouted up, we really know that they exist, and something more. The mere fact of the existence of such companies has done more to retard the progression of electricity in its applications than to push and elevate it. Now and then a party who wishes an installation of electric light falls into the hands of a drummer who represents such a 'Cheap John' Company, and, with the eloquence of a lightning-rod man, he succeeds in inducing the above said party to try his system (as he calls it). Then they bring their traps. The machine, for instance, is a direct piratical infringement on another man's machine—the only difference from the original is that it is painted red instead of brown—and naturally, of course, is less efficient. Their lamp is also an abortion of the lawful lamp; in fact, everything they have encroaches on other men's ideas. Well, then they install their light—perhaps it is done by a youthful prodigy, who as a boy showed his early ingenuity by taking apart the works of a clock and putting them together again, so that a fond mother thought he would be an Edison No. 2. His father, who owns one half of the shares of the Cheap John Electric Light and Power Company, manages to find a berth for his son as engineer to the company. This inexperienced youth has the audacity to begin to install the so-called plant. He had learned while at school that one wire must be connected to the positive pole, and the other wire to the negative pole of the machine. He also knows that the machine is to be put upon its base. His books tell him that pure water is an insulator, and therefore he takes no precaution against damp and watery places where his wires may run. Then, again, he says, "Ain't they covered with zinc oxide? That won't let any fluids through." He will also talk about the theory of potential to somebody whose path in life has never led him to be entangled with electricity, and will go on to say that in order to 'comprendre' the subject one must be well versed in the higher branches of mathematics. He will have the cheek to ask you if you understand mathematics. When he is introduced to you he will generally burst out, as if it were irresistible, saying, 'When I was at the University of Edinburgh, A l'Ecole Central de Paris, or Das Polytechnik von Wien.' Yes, he takes great pride in the mere fact that he was at one of these learned institutions; but he don't tell you that he spent all his time in rowing and football, in going to the 'Cafés Chantantes,' or at the 'Bierhäuser,' drinking himself sick. These qualities he considered the most important factors of his education, and it made him a first-class society man. His studies were secondary matters; study is tedious, and he did not want to ruin his health, for the captain of the club told him of a man who studied so much that he was overworked and got crazy. Of course he thinks differently now, and when he started his installation there was a gushing of electricity at the wrong spot. The armature of a machine is burned, and is sent to the factory to be repaired or replaced, he himself knowing no more of what is inside of the armature, as it seems to him, than he knows of the man in the moon. He gets another bobbin, and this time his main lines and branches give a greenish light, but the lamps are black. Perhaps he thinks that he has discovered some new law or theory that is unknown to the scientific world. While he is trying to solve this new problem the proprietor of the place rushes in, perspiring, swearing, and calling him impious names—telling him if he don't hurry out with all his traps in just about one day he will pull them down and resign him to the mercies of the big bulldog waiting for human gore just by the gate. This takes some starch out of the young man. But what is the result? The proprietor swears he will never have any other electric light, and also warns his brother manufacturers, giving them the experiences he has just met with. Thus the reputation of an honest and lawful firm is soiled by these Cheap John firms, and also by

* The discovery referred to is that of the Leyden jar.

Digitized by Google

inexperienced men. It is ten to one that a party having gone through such experiences will always retain some prejudice against the electric light. One might naturally ask why the inventors do not take proceedings against such concerns? It is simply this, the original inventor does not take any notice of them, as the business they do is so small that such a course would be but a waste of time and money. I dare say some would feel flattered if originality would contest with piracy. We have one consolation, and that is a disease which generally infests such companies, called in legal terms the 'winding-up' disease. We read almost every week of some of these 'petite' concerns being extinguished under its influence. It will be then, and only then, when these shabby and crooked associations will give up the 'spark,' that electric light can pass along unprejudiced, and realise the former expectations."

Our correspondent is not far wrong, though in some parts his statements may be open to misapprehension. He does not intend to argue against small companies, or private firms undertaking work. His crusade is against speculators forming a company, palming off pirated goods as the real thing, and employing incompetent men, men who are pitchforked into positions of responsibility, not because of their capacity, but because of influence. We have not one word to say against the employment of "sisters, cousins, and aunts," except in cases of incapacity.

The following excellent letter embodies not the feeling of the writer only, but a very widespread dissatisfaction, as might be proved by the quoting of letters and opinions. The makers of lamps, too, must be constantly on their guard to see that the manufacture is carefully carried on without degeneration. The letter is as follows:—

"Replying to your inquiry as to our opinion on the present position of the electric light industry, we submit to you the following notes, and trust they will not be deemed by you to take up too much of your valuable space. Electric light installations may be broadly divided into two classes. 1st. Central station lighting, implying undertakings which from their magnitude can only be undertaken by joint-stock companies, and which require certain rights of privilege and rights of way necessitating the control of the Board of Trade. 2nd. Private installations, where the whole outlay is incurred by the user of the light, on the same principle as any other outlay in machinery or premises necessary for the purposes of his trade. The state of central station lighting is in a 'comatose' state, and likely to remain so until the vexatious and prohibitory regulations of the Board of Trade are altered. A committee has been formed with a view to obtain these alterations, and no doubt will do some good. At the same time we are rather surprised to see how little representative this committee is, private manufacturing firms, who have, after all, carried out most of the electric lighting in the country, being hardly represented at all, and the greater part of the committee apparently representing the few remaining electric light companies who have weathered the storms of the last two years. As regards private installations, there is in our opinion no manner of doubt that an enormous extension will take place during the near future in mills, works, ships, &c., having steam or water power to spare, provided certain difficulties can be overcome. The direction in which this increase should take place will be far more in incandescent than in arc lighting, because the latter is suited to only a fraction the number of cases that the former is. The dynamo and arc lamp have arrived at a stage of improvement which leaves not much to gain in the future. It is far otherwise with the incandescent lamp. We know of nothing connected with electric lighting so utterly unsatisfactory as the efficiency and durability of the incandescent lamp. We know of nothing more open to improvement in all the conditions of its manufacture and sale. A purchaser of these lamps is told that they will last with fair usage 1,000 hours. He orders a parcel of lamps to give 20 candle-power, and work at 100 volts. If he asks such a question he is told that they take 45, 60, or 70 watts, according to the maker. He is perhaps a contractor fitting up a mill, and the representations he makes to the mill-owner as to the durability are the echo of the character imputed to the lamps by the makers. Now, we as such contractors have bought some scores of parcels of lamps the last six months under the above representations from different makers, and our almost invariable experience is as follows:—First, that though we buy lamps, for example, to give 20 candle-power at 100 volts, and carefully keep the potential of current much below this even at the terminals of the machine, a considerable proportion of the lamps give out in the first week of running. Second, that when we have taken the trouble to test the lamps before sending them out to see what watt-power they take to bring them up to a given standard of candle-power we invariably find there is a wide variation in the limits of watt-power required. A parcel of lamps, for instance, said to take an average of 65 watts will consist of lamps of every grade of efficiency from 50 to 70. The significance of these facts lies in the consequent deduction that either you must run these lamps so that a large number are little better than what Mr. Trotter calls 'red hot hair pins,' or you must run them so as to involve a risk of a considerable number very quickly bursting. Third, we find no marked advantage in these points in lamps bought from a maker claiming great durability at a cost of an expenditure of $3\frac{1}{2}$ watts per candle-power in the lamps and those supplied by a maker claiming an efficiency of $2\frac{1}{4}$ watts per candle-power. Now, we say advisedly, from our own experience, that *nothing* tends to hinder the progress of incandescent lighting so much as the little dependence to be placed on the durability of these lamps. Coupled with the high price asked for them, an increased durability in the lamps would be a great gain, and a diminution in price a still greater one, because the latter is a tangible advantage demonstrable to everyone, while the former requires a considerable amount of faith and a good many trials before it can be demonstrated as being the character of any new lamp offered. It is evident to anyone at all conversant with the manufacture of incandescent lamps that they can be made for less than 1s., and therefore should be sold for less than 5s. Apart from the efforts of makers to keep the price up, the main justification of the high price of lamps is doubtless the great variety of types asked for—every voltage, from 45 to 100 volts, having to be supplied. If two or three recognised potentials were adopted in the trade as standard lamps—say, 50, $66\frac{2}{3}$, and 100 volts—and these lamps were at a much lower price, leaving lamps taking intermediate potentials at present prices, the demand for and output of those three types would so largely increase that they could soon be sold at as good a profit to the makers as the 5s. price now brings them. But this determination of the best potentials for standard types of lamps should not be left to the makers, but be referred to a committee of those interested in the advance of incandescent lighting; and the same committee might investigate the various conditions under which incandescent lamps are usually worked, to see if there are any points detrimental to their life or otherwise which are not yet sufficiently investigated. In any case it is earnestly to be hoped, in the interest of electric lighting, that there will be no attempt to secure a monopoly of any branch of it to any financial company. A kindred industry has been crushed out in this manner, and the country

Digitized by Google

practically deprived of a valuable invention for many years to come, and the outlook for electric lighting would be most dismal were the same history to be enacted in its case. If this does not happen, and if the price and durability of incandescent lamps are (as everyone knows they can be) greatly improved, we need have no fear as to the future of electric lighting."

Another correspondent, writing under totally different circumstances, corroborates the views above put forward with reference to the Electric Lighting Act, but says:—"I do not consider that this deserves all the blame cast upon it. However easy it had been, the bogus companies would not have paid anything to the shareholders, and the removal of the restrictions (if effected) will be used in an attempt to bleed the public still more, and nothing will be done to the good of electric lighting until all the company mongering is done with, and the companies swept away, and the sooner the better. Should the Board of Trade give way and more money be raised, the effect will be that electric lighting will receive another check."

Upon incandescent lamps he writes as follows:—"The principal thing to be desired is greater duration of the filament in the incandescent lamps, combined with great efficiency, and from personal observation I am inclined to think that the life of a very large percentage of lamps is cut off from want of equality in the filament itself; *i.e.*, a certain spot in it seems to offer more resistance, and the greater development of incandescence or heat at that spot seems to nip it asunder, and yet nothing is perceptible to the eye. Another great practical difficulty is the varying E.M.F. required by the filaments. Although nominally all sent out as equal, the variation is so great that in a room containing, say, 200 to 500 lamps the varying brightness is very perceptible to the eye, and the brightest ones soon go. If you buy, say, 1,000 at a time, so as to pick out the lamps, you are defeated, for the larger number you get the less carefully they are selected, and, apart from this, in an installation of 1,200 lamps you would need a stock of about 10,000, and besides the wasted time selecting, what is to be done with all the rejected ones? A large number are also defective at the eyes, so that the first attempt at using them spoils them. I calculate that those trivial matters alone would make or lose a 5 per cent. dividend to shareholders without waiting for a theoretically perfect lamp. With regard to the E.M.F. allowed, it seems necessary that it should be fairly high, for it will never pay to lay down mains sufficient to supply every house in a district large enough to carry current with a low E.M.F.; neither must the E.M.F. be too high, because however perfect cables may be made it is certain that, allowing for the rough handling of workmen, &c., any cable would be very short-lived placed underground. A system of secondary generators also seems to be necessary, because it must be possible to light or turn out single lamps, and up to the present high resistance lamps possess in a higher degree the faults of the low ones, and one or two of their own. An E.M.F. of 400 to 600 volts will be high enough for fair economy in cables, and quite as much as an average cable will stand; a secondary generator having an efficiency of 85 per cent. would pass muster. Secondary batteries in any of their present forms are a failure as regards town lighting. With regard to price, electric lighting will command 50 per cent. more than gas readily. Engines and dynamos, both in price and efficiency, leave little to complain about, the actual cost being small compared with the total capital required. In conclusion I feel that making the best use of our present knowledge will give good results to all concerned, and every advance make things better still."

Mr. Lever writes very fully as to his experience, which, no doubt, is not unique; but, as he puts the matter somewhat differently to either of the other correspondents already quoted, we herewith give his remarks:—"My experience," he says, "of electric lighting in this country is that the public is very slow to move in the matter. Until the Electric Lighting Act be materially altered, we shall never be able to do much with incandescent lighting. Take the Manchester district for instance, where gas is supplied at something like 2s. 6d. per thousand feet, or a little higher than this. The gas is of excellent quality, and gives about 21 candle-power with a burner consuming, say, 4ft. per hour, or, in other words, a 4ft. burner gives a better light than a 20 candle-power Swan lamp. Moreover, the Manchester Corporation light all the streets in the city free, and yet make a clear profit of £500 every working day in the week, or £150,000 every year. Imagine an electric light company competing with this! The greatest field for us to work in lies, in my opinion, in engineering work, foundries, workshops, &c., and here I have always found a great prejudice against incandescent lights. What is required is an artificial daylight—if I may use the term—a light by means of which the men can be watched and better superintended than by gaslight, and by means of which the work can be done more quickly and with greater precision than by gaslight. This the arc light alone can give. It is necessary, first of all, that the inventor, patentee, or whoever else it may be, who is 'pushing' a particular system of arc lighting, have the greatest confidence in that system, and he must be convinced in every way that it is thoroughly practicable. He must, indeed, imagine that there is not a system anywhere to equal that which he has to offer, but, at the same time, he should be careful not to say 'nasty' things about other systems, which, I am sorry to say, some people do. He must, however, be prepared to meet with disappointments and anxieties, which invariably accompany the introduction of new inventions. In the field, then, in which I say there is the greatest scope we meet with three classes of people:—1st, those who are quite content with gas; 2nd, those people who say they cannot afford; 3rd, those who would adopt the electric light, but think the whole thing is in its infancy, and imagine that every day some discovery may 'crop up' which will send all the present inventions into oblivion. The first class are luckily not very numerous; so we may leave them alone until they change their opinions. The second class of people only want the matter bringing well before them, the advantages pointed out to them, and they will soon be convinced that it will pay them. The system should, therefore, be a cheap one. We may say the same in regard to the third class of people, only that the efficiency of the dynamos, lamps, &c., should be pointed out. They should be convinced that any improvements which will be made can only be 'step by step' improvements. The inventor, patentee, &c., who is introducing the system should be willing to put his system in the works on trial if asked to do so. If a man has not sufficient confidence in his system to permit of his doing this, the sooner that man improves his system the better. A reputation must be gained, and it must have a beginning. It is unreasonable to expect any business man to take up a new invention without knowing whether it will suit his purpose or not, and he naturally wants a trial. The system of arc lighting should be simple, easily understood, and not liable to get out of order. It is not sufficent that the inventor, patentee, &c., employs his own men to work the lights whilst they are on trial. The intending purchaser should have the system in his own hands, and employ his own man or men to look after the installation. If after the necessary instructions be given the system will not

Digitized by Google

work, it is not a practical system. Perfection of feed in the lamps means complicated mechanism as a rule, and such lamps are unsuitable for workshops, &c., for this reason. The system will most likely be tried from some shafting which is driven by the engine working all the machinery. If a large number of arc lights be required, the fact of a separate engine having to be provided very frequently runs the price up so high that those who would adopt the electric light are debarred from doing so. Hence the system should work with a reasonable variation of speed on the dynamos. So long as a lamp is practically steady, it is all that is required. Everything connected with the system should have a good workable margin; nothing should be 'cut' too fine, and all weak points should be remedied immediately they are discovered. Now I do not think there are more than half a dozen systems in this country which will stand this test, and it is a test I find which will be necessary in order to do any great amount of business. The commercial aspects may not look encouraging, but it is surprising to find how quickly one man follows another in adopting the electric light. An installation successfully carried out in one works brings dozens of people in the same line of business to see it at work. They are told that the light was tried as an experiment; that their own men can easily manage everything in connection with the installation, and this brings business. The arduous task of trying the experiment in some one else's works or foundry is not very often repeated. Other intending purchasers have seen the lights at work, they have seen a successful installation, and they don't like to be 'behind the times.' Business spreads very rapidly in this way, and inquiries come from unsuspected quarters. One thing is evident, viz., that those engaged in electric lighting must not sit still and expect orders to come to them. Some of them have done this long enough, and the sooner they bestir themselves the better will be our prospects."

The ANGLO-BRUSH COMPANY.—With the Anglo-American Brush Electric Light Corporation the past year has been one of considerable activity and progress. The business of the company has been largely extended contemporaneously with marked improvements in their manufactures. Their foundations have been strengthened and prospects improved. Further advance has been made in the development of their incandescent apparatus, the Victoria dynamo both in large and small sizes having been still further perfected, and the development of their incandescent lamp has now culminated in what is known as the Victoria lamp. For this lamp an increased efficiency of about twenty per cent. and a longer life are claimed, while a greater uniformity of light is obtained. In arc apparatus the progress has been equally great. The new Brush armature has been put into the market, whereby the output of any Brush machine has been raised by about forty per cent., while the horse-power absorbed per light is diminished. The new ratchet arc lamp has also proved highly satisfactory in giving a steady light. A complete system of switches, cut-outs, and fittings of every kind has been brought out by the corporation and put into practical work, and has proved the reliability and easy management of incandescent electric lighting when installed in a workmanlike manner at the outset. It is only to be expected from this advance that the corporation have done a large amount of profitable work. Among the many installations completed by the corporation during the year the following may be mentioned :—The Forestry Exhibition at Edinburgh, which was exclusively lighted by the corporation, to the complete satisfaction, we understand, of the committee; Messrs. Courtaulds at Braintree, Essex; Messrs. Gray, Hull; the Driffield Cake Company, &c., while apparatus has been supplied for lighting Buckingham Palace, Grand Hotel, Bank of England, Gaiety Theatre, Plymouth New Pier and Promenade, and the Fine Art Exhibition in Bristol, &c. Shipments have been made to all parts of the world, including Cape Town, Australia, Germany, Moscow, Norway, and Sweden, &c. Among the best records, however, of the work done by the Corporation during the past year are installations of the electric light carried out for the Admiralty on board Her Majesty's ships of war. For the purposes of ship and search lighting the corporation's plant has been largely called into requisition, and is now in use on board the "Colossus," "Ajax," "Bacchante," "Conqueror," "Cleopatra," "Dreadnought," "Dolphin," "Linnet," "Leander," "Reindeer," &c. Electrical installations have also been supplied to Her Majesty's War Department and the Northern Lighthouse Board, and this class of business has been, through the medium of agents, extended to merchant ships and foreign navies. In a *résumé* of the work done during the past year the very prominent part taken by that company in the agitation for a reform in electric lighting legislation deserves notice. The officers of the corporation were, we believe, among the first to draw the attention of the public to the onerous conditions imposed upon electric lighting companies by the Legislature, and it is to Lord Thurlow, the chairman of the corporation, that we owe the organisation which led up to the recent interview with the President of the Board of Trade, and has now assumed the form of a powerful committee, whose object it is to confer with the Board of Trade, and otherwise to prepare the way for the early amendment of the Electric Lighting Act. Thus, though the past year may be looked upon as having been one of great depression in electric lighting circles, it will be seen from this brief summary that the Brush Company have been active not only for the benefit of their shareholders, but also in the interest of the industry generally, and have made real and substantial progress, so that with the improved outlook for the coming year this company may be congratulated upon its position and prospects.

Messrs. CROMPTON and Co.—During the past year this firm has been busily engaged in manufacturing dynamos, arc lamps, and all the various accessories required for incandescent as well as arc lighting, and for the electrical transmission of power. The works in Chelmsford have been greatly enlarged, and the number of men now employed is greater than at any previous period. The introduction of the new Crompton dynamo is the most important feature of the year. This dynamo, as most of our readers will remember, is a development of the Gramme ring type of machine. The armature core consists of a very massive ring made up of thin discs of Swedish charcoal iron fixed on a central steel spindle by short arms of phosphor bronze, which are dovetailed into thin discs. At intervals gaps are left for ventilation. The winding consists of a single thickness only of coils. The field-magnets are very massive and are also of soft wrought iron. These machines give exceedingly high E.M.F. at a slow speed and with low armature resistance; there is hardly any lead at the brushes, and the sparking is *nil*. A considerable number of these machines, varying from 60 to 800 lighters, have been sent out; three of them, designed to run 1,000 lights each, are well on the way towards completion.

Three large machines, each driven direct by a three-cylinder compound Willans engine, have been constructed as exciters for the enormous Gordon machines about to be put down at the Paddington Station of the Great Western Railway. Three large machines of similar construction are being constructed for the Brazilian ironclad the "Aguidalan," the lighting of which

Digitized by Google

has been entrusted to this firm. They have constructed six sets of combined engines and dynamos for lighting the trains of the Great Eastern Railway, which will work their suburban traffic on the Epping Forest line. The engines used are the "Tower" engines made by Heenan and Froude, and the whole arrangement is extremely compact, measuring about 3ft. 6in. long by 1ft. 8in. wide by 12in. high. We hear that these little engines and dynamos have given great satisfaction, and this department of train lighting promises to be a prominent feature in the firm's next year's trade. Turning now to arc lamps, Messrs. Crompton have turned out some 600 double lamps of the Crompton-Crabb type, and their use is rapidly extending. Those put up a year ago for the Forth Bridge works have stood extremely rough usage, with entire immunity from breakdowns; and, although the high price of carbons in this country prevents arc lighting from attaining the prosperity and development it has shown in the United States, there is every reason to believe that the uniformly good behaviour of these lamps is contributing in no small degree to a renewal of the demand for arc lighting plant. Messrs. Crompton and Company have been working out with Mr. Willans the development of the electric governors brought out by them and Mr. Wilson Hartnell. The large engines at Victoria Station are now controlled by these governors, and the current supplied to the lamps thus employed has been maintained within a narrower percentage of the standard E.M.F. than has, we believe, ever been the case at any electric lighting station either in this country or America. Other specialities of Messrs. Crompton's manufacture have been the current and potential measuring instruments invented by Messrs. Kapp and Crompton, and described by us. Several hundred of those instruments, all made and calibrated at Chelmsford, are now in daily use in the hands of the public. With the kind assistance of Lord Rayleigh, Messrs. Kapp and Crompton have lately been able to obtain verified readings of correct multiples of the new standard volt at 20, 50, and 100 volts. They have also received from Mr. Weston in America a table of independent tests which prove conclusively not only the accuracy of the original calibration of these instruments, but also that they retain this accuracy even after rough usage and travel. Mr. Weston's tests showed a duration throughout the entire range of the instrument of less than $\frac{1}{4}$ of a volt from his standards. The list of separate installations carried out by this firm by themselves and by their agents is an exceedingly long one. We will only refer to two of them. First, that at Victoria, which has been so recently described by us that we need only call attention to it as undoubtedly the largest and most complete in the United Kingdom; and, second, that at the Palsgrave Restaurant as one which, though belonging to a previous year, is interesting in that it has been tried in the balance with its rival, gas, and has not been found wanting. In the first instance, as the maintenance of the machinery at the Palsgrave Restaurant was found to be very costly, it was thought, erroneously as it has turned out, that by discontinuing the use of part of the electric light and by substituting gas for it, some money saving would be effected. The partisans of gas were highly jubilant, and our contemporaries who write in the gas interest were proportionately triumphant. However, after a fair trial of the gas, it has been conclusively shown that the high cost of maintenance of the complicated machinery in these buildings was not due to the electric light but to other causes, and that the electric light was not more costly than gas. It has therefore been decided to discontinue the gas and go back to the electric light.

THE HAMMOND ELECTRIC LIGHT COMPANY.—This company notices on all hands a more sensible appreciation of the advantages of the electric light, and less of that wavering indecision which has characterised the would-be user hitherto. Satisfaction is felt by those interested in the company that the installations put up two years ago have been running without any more trouble than a little attention now and then to the wearing parts of the apparatus, and this has been specially the case where the apparatus is generally severely tested by dust and smoke. Among the installations carried out are the following:—Messrs. J. Readhead and Sons, South Shields, one 16 arc light apparatus; St. Peter's College, Cambridge, complete plant for 150 lights, the generator being a Ferranti machine; Messrs. J. and J. Colman, Norwich, 1,000 lights run from a 1,000 light Ferranti machine, similar to that exhibited at the Health Exhibition; William Whiteley, Esq., Westbourne-grove, W., a 1,000 light machine; Central Marine Engineering Works, 16 arc light plant, erected only; Stanner's Closes Steel Works, Walsingham, an extension of arc lighting; Civil Service Stores, Queen Victoria-street, incandescent lighting of board room and offices; Messrs. Denny and Brothers, Dumbarton, incandescent lighting for two steamships; James Laing, Esq., Sunderland, incandescent lighting for one steamship; T. C. Eltringham, Esq., South Shields, arc installation, &c. They have during the year produced, in the latest type of Ferranti machine as exhibited at the Health Exhibition and awarded a gold medal, a machine which bids fair to hold its own in the struggle for existence. A new direct acting engine has been designed, and has been working satisfactorily at the works in Appold-street, which is said to embody many improvements. We shall doubtless shortly hear more of this engine.

LATIMER CLARK, MUIRHEAD, AND CO.—During the year this old established firm has been formed into a private company, Mr. A. Le Neve Foster, late of the Silvertown Company, joining as works manager. The work of the company is largely composed of general telegraph and manufacturing work. The work of the greatest public interest during the year that has been done is the manufacture of the apparatus for duplexing with Muirhead's patent system the new Mackay-Bennett Atlantic cables of the Commercial Cable Company. The apparatus before being shipped was exhibited at the *conversazione* of the Royal Society, and also at the *conversazione* of the Society of Telegraph Engineers, at King's College; and it is the first time that so large an exhibition of apparatus and of such value has been brought before the notice of these societies. The company have added to their specialities a new and complete system of submarine mining defence, under the patents of Mr. Latimer Clark and Mr. J. P. Gibbins. The company now manufacture the ammeter, voltmeter, &c., under the patents of Professors Ayrton and Perry; also ships' telegraph and speed indicator, of Messrs. Farquharson and Lane; Mr. Mance's cable testing method, &c. This company has the agency and manufacture in England for the arc lamps of Captain Cardew, R.E., and M. Werner, of Cologne, which are very efficient working lamps. They have lighted up the new premises in Fleet-street of Sir J. Whittaker Ellis, Bart., M.P., with incandescent lamps, using a Victoria dynamo.

J. H. GREENHILL has been one of the most active agents in the development of electric lighting in Ireland. We note with a considerable amount of pleasure that he has extended the light installations in various places during the past year, as well as put up new installations. It is a good sign that people are satisfied when they extend the lighting. Thus Messrs. Harland and Wolff, the well-known shipbuilders, have extended their lighting, and now have in use 250 incandescent lamps and 43 Crompton arc lamps. In addition this firm has 1 Brush dynamo, 18 Brush lamps, 3 Brockie lamps, and 1

Digitized by Google

Belfast Electrical Appliance Company's lamp; also 1 Siemens exciter and distributor incandescent machine for 100 lamps. W. J. Shaw and Sons, Limerick, have also extended the light, and have now in operation 3 machines and 310 lamps. J. and T. M. Greeves, of Belfast, have 2 machines and 250 lamps. Among other new installations during the year we may name St. Patrick's Industrial Schools, Belfast, 1 machine 60 lamps, and Messrs. Matterson and Sons, Limerick, 1 machine 130 lamps. This firm has also a large Maxim light installation. Mr. Greenhill, speaking of his experience in lighting his own house with ten incandescent lamps, says:—"It may be considered that it was not worth while introducing the electric light for so small an installation, but this is entirely an erroneous impression, as although I have only one of Crossley's new half horse-power gas engines for the dynamo, yet we can get from 8 to 9 lights of 20 candle-power each quite easily. I have a set of 24 Planté cells, but seldom use them, as I find the lights are perfectly steady without them. The engine and dynamo give no trouble whatever, except the act of starting and stopping; the latter can be done in my house without going out to the little engine house where the machinery is. This installation has been running constantly since Sept. 12, the only hitch during that period being on an occasion when the lights went out for a few minutes by reason of the lacing of the belt giving way, and this could have been avoided by an examination of the belt before starting. If it was only more generally known how pleasant the electric light is, and conducive to health and the preservation of furniture, plants, &c., and how it lends itself to the decoration of the house, it would be far more used by those having the facility for driving the dynamo either by water power, gas, hot-air engines, or steam. I think there is a good opening for a thoroughly efficient hot-air engine for driving the dynamos in country mansions where gas is not to be had, and water power not available."

Mr. C. Lever.—During the year the electric light has been put into part of Mr. Lever's house at Bowdon. The billiard room is lighted by 45 Swan lamps of 20 candle-power each, whilst 18 Swan lamps of the same candle-power, and one Lever arc lamp of 2,000 nominal candle-power, light the offices. The power is obtained from a Marshall's vertical engine and boiler, and two Bürgin machines—one of which is always kept in reserve—generate the requisite current. This system of lighting has been adopted in the spinning of coloured goods by Messrs. W. Blackburn and Co., Clarence Mill, Cleckheaton. Six Lever arc lights of 2,000 nominal candle-power each are used for lighting the combing and hanking rooms. A specially designed compound-wound Gramme machine is used for generating the current, and is driven from the shafting which works the machinery in the combing room. These lights were put in last summer, and although the plant has been left entirely in the hands of the firm's workmen, there has not been a single hitch so far, the lights being run morning and night. Messrs. Richards and Co., of the Atlantic Works, Broadheath, have adopted this system, and are now extending the lighting by means of smaller arc lamps of 1,000 nominal candle-power in lieu of Swan's incandescent lamps, which are used in the offices. The dining room is lighted by 20 Swan incandescent lamps of 20 c.-p. each, and about 15 Swan lamps of 20 c.-p. are used for the small lathes and for lighting small corridors, &c. Nine of the small arc lights are being put in for lighting the offices and gallery where the larger arc lamps are unsuitable, so that this firm has the whole of the works lighted with thirty arc lamps and about thirty-five Swan lamps. Five special Gramme machines are used for the arc lighting and a small Phœnix machine for the incandescent lights. Mr. Lever, like many other manufacturers, has spent a good deal of time in perfecting an alternating current dynamo machine. Although the results obtained were very feeble at first, with some important improvements in the details the machine now gives infinitely better results. This machine has been designed more especially for working arc lights in series and incandescent lights in multiple at the same time. A plate of wrought iron is the only revolving part in the machine, and this being of one polarity the coils are connected in a different manner to other alternating current dynamos. There are no collectors or brushes on the machine, consequently it can be left in almost anyone's hands to work.

Messrs. Paterson and Cooper, as will be seen, have carried out a number of installations at home and abroad, either directly or indirectly through their agents, and, like some of the other manufacturers, have supplied apparatus to order for work not carried out under their supervision. The dynamo supplied by this firm is named the "Phœnix." Among other installations the following may be mentioned:—Municipal Buildings and Public Library, Leeds; Government Hospital, Christiania; Craig y nos Castle, Swansea Valley; cloth mills of Mr. Isaac Northrop, Embsay; cloth mills of M. Sheard and Co., Batley. Installations for cloth mills of Messrs. Kessler and Co., Bradford; Messrs. J. Bannister and Sons, Bradford; Messrs. J. Gaunt and Co., Farsley; Messrs. Wilsons and Glenny, Hawick. Installations for Messrs. Mechan and Sons, Glasgow; Messrs. Thomas Adams and Co. (Limited), Nottingham; the cloth mill of Mr. J. Blackburn, Johannsberg, Berlin. They lighted the "Tilly" steamship, built by Hanna, Donald, and Wilson, Glasgow; Rusclokbahkens Bazaar, Christiania; Hœgholmen's shipyard, Christiania; Devolo's wool mills, Aalesund; Gyethus paper mills, Drammen; Nilsen and Matthieson's saw mills, Fredrichstad; J. Shibley and Co.'s cloth mills, Batley; J. L. Stewart and Co., Valley Mills, Bradford. Also for J. Mitchell, Snargate-street, Dover; Phillips Bros., The Combination, Holborn; MacNaughten, Love, and Co., Finsbury; J. Smith, optician, York; Blundell, Spence, and Co., Hull, and J. Henry and Co., Bradford.

The German Edison Company.—This company has not hitherto found a place in our annual *résumé*; but it will be seen that it has done a large amount of work. The light has been installed in 128 establishments, which altogether take some 22,000 Edison lamps, the current being supplied from 169 dynamos, driven by engines of collectively 2,500 horse-power. The following are a few of the larger installations:—The Central Station at Strassburgh with 1,960 lamps, five 250-lamp dynamos, one 450-lamp, one 200-lamp, and one 60-lamp dynamos. The piano factory of Emil Ascherberg, of Dresden, is lighted by 250 lamps, one 250-lamp dynamo giving the required current. The Rositzer Sugar Refinery is lighted with 500 lamps, with two dynamos. The King's Theatre at Stuttgart has 1,060 lamps, fed by four 250-lamp dynamos, and one 60-light dynamo. The factory of Hartmann and Sons, of Münster, has 1,000 lamps, supplied by two 450-light dynamos, and one 100-lighter. Messrs. Burensson and Oldroyd in their factory at Sagan have 500 lamps. The Berlin Central Station is supplying current with four 450-light machines for 1,800 lamps. The theatre at Munich has 2,500 lamps, and so on. Besides the installations of incandescent lamps, a number of installations of arc lamps have been carried out. The installations have been for clubs, hotels, cafés, factories, shops, theatres, town halls, and private residences.

The Liverpool Electric Supply Company.—A number of installations have been carried out under the superintendence of Messrs. Holmes and Vaudrey, the managing directors. Among others, the Adelphi Hotel, Liverpool, 200 incandescent

Digitized by Google

lamps; the American Exchange, Liverpool, 24 lamps; the White Star Steamship Company's new works, 400 lamps; Messrs. A. Handyside and Company, Derby, 6 arc lamps; Royal Court Theatre, Liverpool, 6 lamps; Prince of Wales's Theatre, Liverpool, 4 arc and 24 incandescent lamps; Messrs. Hyam, Liverpool, 10 arc lamps; Messrs. Henochsberg and Ellis, Liverpool, 6 lamps; Star Music Hall, Liverpool, 4 lamps; Messrs. Joseph Owen and Sons, 5 lamps; Messrs. H. and C. Grayson, 8 lamps; the India and China Tea Company, Liverpool, 35 incandescent lamps; Messrs. David Rollo and Sons, 5 arc lamps; Thomas H. Edwards, Esq., 20 incandescent lamps. The company is now supplying under rental agreements, from its central station in Rose-street, more than 300 incandescent and 30 arc lights. They have also contracted with the Corporation of Liverpool to supply the electric light to the Free Library and Picton Reading room. The company are also lighting the large ball room and reception rooms of the Wellington Club, Liverpool, 200 incandescent lamps being employed in this installation.

W. T. Henley's Telegraph Works Company early in the year put down new machinery for covering wires with gutta percha, which has been constantly at work since its erection, manufacturing telegraph, torpedo and telephone cable cores, leading-in wires, &c. The company have made several lengths of submarine telegraph cable during the year for various telegraph companies, foreign governments, &c., amongst which we may mention the much-needed cable laid early in the year from the coast of Devonshire to Lundy Island. This cable is one of the strongest, perhaps the strongest, laid off the British coast. It has two sheathings, the first composed of 18 galvanised steel wires, and the second of 15 galvanised B.B. iron wires. The insulation consists of the company's patent ozokerited india rubber. A large quantity of armoured torpedo cable has also been manufactured. It may be mentioned that very satisfactory reports have been given concerning the ozokerited india rubber core put in cables immersed during 1883. A considerable quantity of telephone and electric light cables has been made. The cables purchased by the Commissioners of the International Health Exhibition were made by this company. They were insulated with the ozokerited india rubber, and have given great satisfaction, not a single breakdown having occurred during the exhibition. During the last three or four months of the year the demand for electric light cables, according to this company's experience, has been steadily improving, and leads to the inference that the employment of the electric light is increasing. The demand has been considerably in excess of that for the same period in 1883. The demand for porcelain insulators, galvanised and braided wires, &c., for overhead telegraph and telephone lines, and also in cotton covered, silk covered, and paraffined wires has been fairly good during the year.

The Consolidated Telephone Construction and Maintenance Company.—This company, which was started in 1881 with such bright prospects, seemed under the management of the late Board to have a blight over it, and the report of 1883-4 was one of a most discouraging character; indeed, it looked as if the company was on the verge of liquidation. In May last the shareholders, thoroughly dissatisfied, demanded a Committee of Investigation, and the report of this committee, issued in July, showed such a state of affairs that the shareholders insisted on the resignation of Colonel Gouraud (acting chairman), Hon. H. Spensley, and Mr. P. Carnegy, C.T.E., from their seats at the Board. With fresh blood infused into the Board, the company seems to have taken a new lease of life. The gentlemen who are now in power have for the last six months been actively engaged in putting in order the various undertakings which the company has in hand, and judging from the chairman's speech at the meeting held at the Cannon-street Hotel on the 16th December (which was fully reported in our columns), there seems a good prospect of a sound and lucrative business being carried on under their able and energetic management. The company, besides its ordinary manufacturing business, is largely interested in the River Plate Telephone Company, the Telephone Company of Austria, which company has a ten years' absolute concession to erect exchanges in nine large towns in Austria, and the Edison-Gower-Bell Telephone Company of Europe, who have a twenty years' concession to erect exchanges in Oporto, Lisbon, and elsewhere in Portugal. All the exchanges are doing well and gradually (as seems to be a certainty in the telephone business) working into dividend-paying properties. With the great extension of radius lately granted by the Postmaster-General to the United Telephone Company and its subsidiary companies, the demand for the telephone will assuredly increase greatly, and this increase will favourably affect the Consolidated Company, as under its agreement with the United Telephone Company it has exclusive right to manufacture telephones for the United Kingdom and their affiliated companies under the Bell, Edison, Blake, and Gower-Bell patents. With a steady increase in the manufacturing business and the various exchanges making returns to the parent company, it would seem that the shareholders of this undertaking are now within a measurable distance of a dividend.

Telephony in the South-East.—The Brighton and Hove Exchanges have nearly doubled the number of subscribers. Direct wires have been run between London and Brighton. These are nearly free from inductive effects, and the articulation all that can be desired. The wires are run along the main line of the South-Eastern Railway cross fashion. Business has also been commenced at Eastbourne and Hastings, and exchanges will be opened early in 1885; in fact, several private wires are already at work. It will be necessary, for the due development of telephony, that a much better class of trained engineers be employed, as the constant train of delays and complaints must militate against the enormous development which should await it, and it is much to be feared that the public will have to wait until the present monopoly is abolished; and as Nature's law seems progress, it is useless to suppose that everything is known at present.

Magnus Volk has greatly extended the small electric railway, with the result that there has been an enormous development of traffic, and it may claim to have carried a greater number of passengers than any other electrical undertaking. In electric lighting he has carried out the lighting of the Corn Exchange, Dome Assembly Rooms, Free Library, Picture Gallery, and the lawns. This work has been carried out for the corporation, the extensive lights of the lawn being (as far as known) the first use of incandescent lighting for the purpose. The total number of lamps used in this one installation is about 1,300. Siemens' 500 light new compound machines are used; these show a marked advance in the economy of power. The use of the Maxim 30 candle-power for the Picture Gallery, when driven rather beyond their normal candle-power, has met with great success, the light being all that could be desired, and free from the flicker of the arc.

Although we have incidentally mentioned telephony, telegraphy, submarine telegraphy, transmission of power, &c., this week, we are compelled to leave over the main features of the year's work in these directions to another article.

PAYING FOR SPECIFCATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think that electrical engineers owe you a deep debt of gratitude for the fearless manner in which you have upheld the true interests of the whole profession in this matter.

No one supposes for a moment that Messrs. Mackenzie and Brougham were actuated by any other motives than those of duty to their client in adopting the course they did, and we now know that they were acting strictly in accordance with his express instructions. In fact, as Sir Coutts Lindsay has practically acknowledged, it is he who is to blame, and not the firm that he employed. It is of course open to question whether Messrs. Mackenzie and Brougham acted with due consideration in accepting such instructions.

It is certainly a somewhat new doctrine that a part of the duty of a consulting engineer is to endeavour to squeeze as much as possible out of competing contractors for a particular piece of work, towards lightening his own professional charges to his own client. I think it is by no means difficult to imagine cases in which such a system might be made the means of something very closely approaching a transaction that most men would call by an ugly name.

Suppose that A starts as a consulting engineer, and makes use of the names of B, C, D, and as many more of his friends as he chooses, to draw specifications for work that B, C, and D have not the slightest intention of having executed, and makes the competing contractors each pay a sum sufficient in the aggregate to reward him very handsomely for his trouble. B, C, and D are under no legal obligation to give the work to any contractor, nor, so far as I understand, was Sir Coutts Lindsay.

I trust I may not be misunderstood in the above. I am not for an instant reflecting on the *bonâ fides* of either Sir Coutts Lindsay or Messrs. Mackenzie and Brougham. I am merely putting the extreme case, what might happen in that delightful village called London, where it is believed men of the character of A, B, and C do occasionally harbour. Leaving, however, the question of *bonâ fides* out altogether, suppose that no rogue ever set up as a consulting engineer, and that it would be impossible for him to do as I have suggested. Come back strictly to moral grounds. Is it right that competing contractors should be made to pay for the professional services of the engineer who draws the specification upon which they are to base their estimates, but from which only one can benefit? There is a suggestion in a contemporary, that these specifications contain valuable technical information which, it being important for contractors to be possessed of, it is therefore just that they should pay towards its preparation.

I think that this argument will hardly hold water. It may occasionally happen that a consulting engineer has a wrinkle not in the possession of contractors; but I believe every one will agree with me, that a consulting engineer who inserted in a specification an untried idea of his own would hardly be doing his duty to his client. Knowledge that is required for drawing specifications is gained by experience of the actual working of apparatus, and I believe I am hardly overdrawing when I say that those who make, or enable others to make, experience of the actual working of different kinds of apparatus, are the very contractors who are to compete for the work when the specification is drawn. It can hardly be just, therefore to make them pay for knowledge or experience which they themselves or some of them have furnished.

We come back therefore to our original point. Given the fact, which no one will dispute, that professional work must be paid for where employed, then who should pay for it?

To answer this, let us ask another question. Whom does the work benefit? For it is clear that he or they who benefit by the labour of others are the proper parties to pay for that labour.

The work in this case benefits Sir Coutts Lindsay's clients, and therefore it is they who should pay Messrs. Mackenzie and Brougham for their services. It is they who will suffer if the light flickers or goes out at inconvenient times, and it is they who will benefit if the light is good. Therefore it is clear that they should pay.

Moreover, it is perfectly clear that they will have to pay whatever Sir Coutts Lindsay has to pay in one form or another; and therefore it would be a manifest injustice to make others pay a part where they receive the whole benefit.

Mr. Crompton has rightly pointed out that, however long the public may take in adopting the electric light, and to whatever expense they may put manufacturers and others, it is they, that same consuming public, and they alone, who in the end will have to pay the bill; and I think there can hardly be a clearer or a more direct case than the one under notice. Either by increased attendance, or by increased charges, Sir Coutts Lindsay's consuming public—the ladies and gentlemen who patronise the Grosvenor Gallery—will have to recoup him for the expenditure which he is now making for their comfort. This being so, as the amount which Sir Coutts Lindsay will receive from his clients in repayment of his present outlay will be independent of how much or how little he pays for professional assistance, and we may therefore assume that the receipts will exceed the expenditure, is it just on the part of any consumer to endeavour, after putting a certain body of men, who have no interest whatever in his venture, to a certain expense in preparing estimates for his benefit, to draw from them (the contractors) a further sum in addition to that he receives from his clients, for which sum he gives no return whatever?

A consumer, having determined to use a certain commodity, has always two courses open to him, supposing that he has not sufficient practical acquaintance with the commodity to risk being his own buyer. He may confide in a firm of suppliers on whom he can rely; or he may endeavour to obtain the benefit of competition between suppliers, and thus obtain his article at a cheaper rate. If he adopts the latter course, however, in the case of very many commodities, always supposing the consumer to have little practical experience himself, he must, to protect himself from unscrupulous suppliers, employ the assistance of some one who is skilled in the particular subject the consumer has in hand, and who has the practical experience which he lacks.

In many cases, notably in the present, in order that suppliers may compete on equal terms, and that there may be no room for dispute when the work is done, detailed specifications have to be prepared. Are these specifications prepared for the benefit of the consumer or the supplier? Clearly the former. Moreover, in the majority of cases, the labour involved is the same whether one supplier tenders or a hundred, the ninety-nine being merely copies, involving only clerical or printer's work.

Suppose that only one supplier tendered. To carry the matter to its logical conclusion, the unfortunate man ought to be charged with the whole cost of preparing the specification. Would this be just? In this case it would, as the supplier would simply add to his estimate the cost of preparing the specification, plus his profit on that as a business transaction. If custom arranged that the successful contractor paid the professional charges, it would also be just, as the consumer would really pay it, but in another form, and possibly with a little interest.

I think, however, a consumer would hardly be prepared to sanction an arrangement by which the man was paid not by the man in whose interest he was paid to watch, but by the man he watched. To make the body of competing suppliers, whatever be the commodity, pay the cost of skilled advice and overlooking between them, while only one can benefit, *must* be unjust.

There only remains to consider the grounds upon which Sir Coutts Lindsay based his instructions to make the competing contractors pay a part, viz., to lessen his own expense, which has been already dealt with, and to see that *bonâ fide* contractors applied for specifications.

It is somewhat difficult to see that Sir C. Lindsay could be injured to any great extent if any reasonable number of firms applied for a specification and did not afterwards tender. Suppose the case of a firm who would tender if the conditions were such as they could accept. How are they to know what the conditions are? So that by refusing copies of the specification, which, once made, can be reproduced at small cost, thereby saving possibly a trifle on the professional bill, he

Digitized by Google

may have deprived himself of the services (for that is what it amounts to) of a valuable competitor.

There is, however, as Mr. Crompton points out, a simple and efficacious remedy, ensuring thoroughly that Tom, Dick, and Harry shall not obtain possession of one of the precious documents unless they really intend to make a proper use of it, and that is to charge a fee, returnable on receipt of a *bonâ fide* tender. No firm of standing would object to that arrangement, which, as anyone who will peruse the front columns of the *Engineer* can see for himself, is almost universally adopted by corporations, railway companies, and others.—Yours, &c.,

SIDNEY F. WALKER, M.S.T.E. and E., M.I.M.E.

195, Severn-road, Cardiff, December 24, 1884.

EVOLUTION OF THE ELECTRIC RAILWAY: Its Commercial and Scientific Aspect.*

BY DR. W. ADAMS, MEMBER OF THE ENGINEERS' CLUB OF ST. LOUIS.

Since Denys Papin, in 1687, proposed the transmission of power over long distances pneumatically, human genius in every age and clime has been struggling to solve the problem of power transmission in accordance with the principles of economy.

It is primarily the more desirable to effect this, that advantage may be taken of the various forces of nature, such as the ebb and flow of the tide, swift-running streams and waterfalls, for the performance of work at points located awkwardly or at some distance from the source of power.

Furthermore, since the advent of the steam engine, the economy attending the centralisation of power and its distribution to isolated consumers, even when thus artificially developed, has been fully recognised by all engineers. Various methods have been proposed, for accomplishing this; such, for instance, as pneumatic, hydraulic, cable, and steam transmission. But all have thus far failed to practically meet the requirements, until now electricity has entered the field as a contestant, and seemingly put an end to competition; since it has been both *theoretically* and *practically* demonstrated beyond question by a host of noted scientists, some of whom have the honour of being recognised as among the greatest living engineers—such for instance, as Sir William Armstrong, Sir Frederick Bramwell, Dr. Werner Siemens, Sir William Thomson, Professor John Perry, Professors Preece and Ayrton, M. Marcel Deprez, Count du Moncel, and many others of like scientific celebrity—that electricity may be used as a medium of power transmission with greater facility and economy, all things considered, than any of the other known methods.

It is the invention of the dynamo-electric machine that has rendered possible this method of power transmission. Such a machine yields electricity as the result of rotation imparted to it by the expenditure of mechanical power derived from some natural or artificial source. A portion of this power may be reclaimed by causing the electric current generated in one dynamo machine to circulate through a second similar machine. Hence, all dynamo-electric machines—the name signifying from mechanical motion to electricity—become electro-dynamic machines when the condition of affairs is reversed, and an already existing current of electricity is caused to circulate through them. The second or reclaiming machine, or translating device, as some call it, will, when a "series wound" machine, rotate in an opposite direction and deliver up a certain proportion of the mechanical power expended upon the pulley of the first. This constitutes the basis of the electrical transmission of power. These facts are generally admitted to have been first pointed out and demonstrated by Messrs. Fontaine and Gramme, at the Vienna Exhibition of 1873, although Pacinotti had, in 1861, constructed a motor identical in principle with the modern dynamo-electric machine, and clearly pointed out its reversibility. Considering this question of electric transmission of power from its two principal standpoints—first, as regards the electric current developed from the mechanical power (the steam engine, for instance); and, second, as regards the amount of mechanical power reclaimed from this current at the distant point through the instrumentality of an electro-dynamic motor, the efficiency of the system is 70 per cent., allowing 7 per cent. for loss by leakage in and resistance of the connecting conductor. The amount of energy lost by the two conversions from mechanical motion into electrical energy, and from electrical energy back again into mechanical motion, is a fixed quantity, and practice has demonstrated this to be 13 per cent. from the first, and 10 per cent. from the second process, when the most efficient types of electric generator and electric motor are used.†

The other element of loss—that by leakage in and resistance of the connecting conductor—will naturally vary with the conditions in each individual case, and will depend entirely upon the size and insulation of the connecting conductor. In general it will, in my opinion, be best to base a calculation upon a 7 per cent. loss in the conductor, allowing 5 per cent. for resistance and 2 per cent. for leakage. This, however, will be governed entirely by the peculiar conditions attendant upon each individual case. The rule given by Sir William Thomson is to the effect that the most economical diameter is secured when the two losses (that is, the loss from heating and the interest upon the price of the conductor) are equal. Knowing the cost of one horse-power of electrical energy in any particular locality, which depends upon the price of coal and the efficiency of the machinery used, and the cost of copper per ton, and remembering the formula $H = \frac{C^2 R}{746}$, the calculation for that locality may be readily made. Assuming, however, the loss in the conductor to be 7 per cent., and the loss in each of the translating devices to 10 and 13 per per cent. respectively, the total loss by transmission becomes 30 per cent.; or, in other words, 70 per cent. of the power expended at the point from which the distribution is to take place may be recovered in the reclaiming machines or electric motors. That is to say, we may deliver within reasonable distances just 7-10ths of the power expended in the first instance. For example: a steam engine of 500 horse-power operated at a central station in the centre of a ten-mile circuit could, by the aid of an electric current traversing a suitable conductor, lay down 7-10ths of its power, or 350 horse-power, distributed among as many different points within that circuit. The fact must here be borne in mind that, aside from all considerations of nuisance and cost of services of engineers, this 500 horse-power may be generated in a single engine for one-fourth the cost, in the way of fuel alone, of generating the power in small engines. Consequently, while we lose 30 per cent. of the power by this two-fold conversion and transmission, we more than make up for such loss by this one item—the gain in point of economy of fuel from the saving effected by the generation of our power in one or two large engines as compared with the cost of developing the same power in a number of small engines. Other than this, however, there are very many more important sources of economy and advantages attendant upon the centralisation of our forces. Such an amount of reclaimed power is far in advance of that obtained under similar conditions with compressed air, pulleys and shafting, cables and steam, and approaches the theoretical efficiency of hydraulic transmission as advocated by Sir William Thomson, with the fact in favour of electricity that it possesses the unparalleled advantage of being almost entirely untramelled with the obstacles presented by distance, while it is at the same time remarkably portable and capable of having its direction and intensity changed at the will of a child. No force can be detected in the connecting portions, that is, in the conductor, such as appears during mechanical transmission with shafting and cables or in pipes with compressed air, steam, or water. The conductor is clean, cold, and does not move, appears inert, and can be shifted, bent or moved in any manner with the greatest facility while transmitting many horse-power. The primary source of power and the point of reclamation may be relatively situated most awkwardly, for the electric conductor, which is simply a copper wire, may be brought round the sharpest corner or carried through the most elegantly appointed private room conveniently and without any manner of annoyance or danger. A conductor carrying many horse-power through a room may be rendered imperceptible. There is no noise, no smell, no dirt, no heat, nothing to burst or give way; and the same circuit which may be tapped to provide many horse-power can be as conveniently drawn from to work a sewing or a washing machine, a small ventilator, a table or desk fan, a domestic flour sifter, an egg-beater, a dentist's drill, a jeweller's or dentist's lathe. So convenient a source of light power will give rise to the invention of many new devices for the mechanical performance of much of the light domestic work which now proves a bugbear in every household.

In mining and excavating operations electric transmission will prove of great value, since it involves no danger and may be carried to points inaccessible to any other form of power. For ploughing by power, trials made in France show that electricity can replace steam with advantage and economy.

In Scotland power obtained from a waterfall has been electrically transmitted one mile and a half with an electrical return of 85 per cent. In Prussia, France, Austria, Ireland, and England, many miles of electric railway in successful *commercial* operation demonstrates the feasibility of, and the many advantages attendant upon electric transmission; for, as we shall see further on, this very principle of electric transmission of power to a distance constitutes the foundation of the modern electric railway, and it is here that this principle finds its pre-eminently important application.

* Paper read before the Society of Civil Engineers, America.

† The lecturer here demonstrated the electrical transmission of power by means of two dynamo machines of about 1½ horse-power each; and also by means of two Holtz machines—one acting as generator, the other as a motor. The electric motor used upon this occasion had been continuously and successfully running the machine-shop connected with Dr. Adams' laboratory for over a year.

10	0·008	0·014	0·021	0·080	0·159	0·333	
50	0·008	0·009	0·010	0·032	0·060	0·134	
100	0·007	0·008	0·909	0·023	0·042	0·099	

From these tables the author, whose name escapes my memory, concludes that in all cases where these four systems are equally applicable, wire-rope transmission is best for distances under 1 kilometre (1,100 yards), and electrical transmission for longer distances.

The following curves, which have been plotted from these tables, represent geometrically the relationship existing between these several methods of power transmission.

From these, and very many other things not here mentioned for want of time, which have already been accomplished, calculations have been based, and these show conclusively that it is possible to render available at every door any desired proportion, within reasonable limits, of the stored-up energy of our continent, in a form at once universally applicable, cheap, noiseless, cleanly, safe and manageable by unskilled hands.

All this is not only theoretically possible, but economically practicable. It is not of necessity simply a dream of a future Utopia. It may be made a realisation of the present—a grand every-day commercial experience.

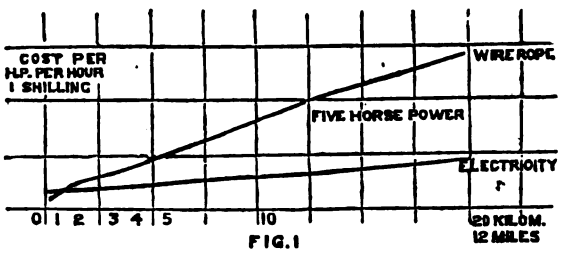

FIG. 1

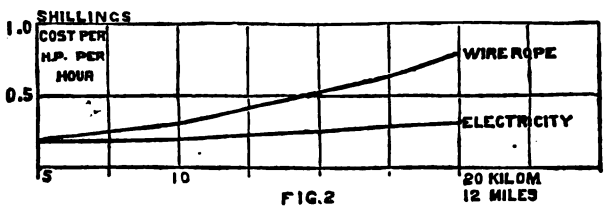

FIG. 2

It only requires that engineers generally and capitalists shall become conversant with these facts, to bring about a transition from the stage of practical *demonstration* to that of practical *application*. It seems strange, perhaps, to some of us, when we consider that these things have been demonstrated facts since the beginning of the present decade, that capital has not been directed in this channel ere this. Great scientific truths, however, become popularised very slowly. They require a long time to become a part of the current knowledge of mankind. Without doubt we all recall to mind how it was fully a century after Copernicus died before the Copernican theory was generally accepted by even the *learned*. And again, how from the time of Hero, who clearly set forth the principle of the modern steam engine, we find no historical evidence of its application to practical purposes for many centuries. Although John Fitch, in 1785, demonstrated beyond all question the feasibility of steam navigation, and worked indefatigably up to the time of his death, in 1798, for its introduction as a commercial feature of our country, it was not until 1807 that capitalists, appreciating the field open to them, came to the rescue, and assisted Fulton to make steam navigation an every-day commercial success; and even so worthy a scientist as he frequently endeavoured in vain to secure pecuniary countenance from the possessors of wealth and influence. With what force the frequently reiterated assertions of John Fitch come home to us now:—"The day will surely come when some one more powerful will get fame and riches from my invention, but no one will believe that poor John Fitch can do anything worthy of attention."

Let us hope the day for reproaches similar to those Fitch indulged in are past, and that capital, with its frequent similar experiences, backed by greater enlightenment and enterprise, will never again be wanting to prosecute schemes based upon scientific facts which bespeak untold wealth for their projectors and promise to confer manifold blessings upon mankind.

As I have already stated, the most important application of this principle of electric transmission of power is exemplified in the *modern* electric railway. Now, I advisedly use the expression *modern*, because the electric railway, like all other inventions, has a history. It is not a thing of spontaneous development, but of gradual growth. In considering its evolution, we must cursorily glance over the history of the "*electric engine*," as electro-dynamic machines have heretofore been christened. The earlier "electric engines" or motors belonged to that class or type known as oscillating or reciprocating engines. First to make an oscillating electric motor was a learned monk, strange to say, of Padua—Salvator del Negro, who, in the year 1881, succeeded in operating such a motor. An oscillating motor, however, has many disadvantages, the most important of which is the fact that the moving part (the "armature") at the end of its stroke is at a considerable distance from the attracting electro-magnet (the "field"). This, in electric motors, is a very serious defect, since the electro-magnetic attraction or pull diminishes in intensity very rapidly, varying, as it does, inversely as the square of the distance; so that when the armature begins to approach the field there will be very little, if any, force pulling it. Hence motors built upon this principle proved very

little more than pieces of physical apparatus. This first motor for producing rotary motion by electro-magnetism, without a reciprocating action, was invented in 1833 by our now deceased countryman, Professor Henry, late of the Smithsonian Institution, a description of which may be found in Vol. XX. of *Silliman's Journal*.

This motor also was but a toy, having the same defect just referred to, as indeed did all motors brought out up to the time of the discovery of the modern "dynamo" principle. Between the time of the advent of Henry's motor and the period of Professor Page's experiments, of which we shall learn further on, Davenport in our own country, Professor Jacobi in Russia, Davidson in Scotland, and Mr. Henry Little in England, constructed electric motors of considerable size. Professor Jacobi propelled a boat by electricity on the Neva, at St. Petersburg, in 1839; Davenport and Ransom Cook had quite respectable electric motors working in New York in 1840; and Davidson ran an electric locomotive in 1842 on a railroad near the city of Glasgow, Scotland. A little later Mr. Little operated an electric locomotive in England. Jacobi's motor was of about two horse-power; that of Davidson was a little over one horse-power, and propelled a locomotive weighing five tons at the rate of four miles an hour. Excitement upon this subject reigned supreme in New York about 1841, when electro-magnetic engines became a kind of mania, and although commercially worthless, hundreds of them were manufactured to meet the market demand.

The experiments of Jacobi, Davenport, and Davidson, proved unsatisfactory, however, as was predicted by contemporary scientists. This naturally caused disappointment and reaction; so that nothing of importance was added to the stock of knowledge concerning the subject until 1845, when Professor Page, of Salem, Mass., revived and gave to the subject a new impetus by the invention of a new form of electric engine based upon the principle of the axial force of electro-magnetism, which proved to be the most perfect electric motor ever invented up to that time. A few years later, Professor Page proposed electricity as a motive power for railroads, through the instrumentality of his own electric engine. This engine proved so successful and attracted so much attention that the idea gained favour to such an extent as to induce Congress to appropriate and place at Professor Page's disposal a sum of money (thirty thousand dollars) adequate to construct and operate an electric locomotive in accordance with his plans. Such a locomotive was built in 1851, and used to propel a train of cars between the cities of Washington and Bladensburg, a distance of five miles. As was natural, such an undertaking created great excitement and discussion in the scientific world, both at home and abroad, more especially because of the governmental sanction and assistance lent the enterprise. The great mathematician and scientist, Dr. Joule, and many others, very properly contended that the system would be too expensive, and that electricity as then generated, could not be used as a motive power with sufficient economy to warrant its adoption on a commercial scale. In fact it was this very discussion which led Dr. Joule to that long and laborious investigation of the mechanical equivalent of heat, which now forms the basis of all our work in thermo-dynamics, and without which we should be groping in the dark.

It was on the 29th day of April, 1851, that Dr. Page made the trial of his locomotive, which ran at the rate of 19 miles per hour, making the trip of 5 miles in 39 minutes. The locomotive itself weighed 10½ tons, including the batteries, and carried 7 passengers. There were many stops and delays on account of the breakage of his battery cells, which were carried upon the locomotive, the jars fulfilling the office of a steam locomotive boiler and furnace, zinc and sulphuric acid in the former case constituting the fuel. The sulphuric acid and zinc were burned or consumed in the production of electricity. This is the principle upon which it was sought to operate all the electric engines thus far referred to. Electricity was here called upon to serve as a prime motor, utilising the energy stored in sulphuric acid and zinc.

The folly of such an effort is manifest, since one pound of zinc costs twenty-five times more, and is not capable of being transformed into as much dynamic force as one pound of coal. Although Dr. Page's hopes were not realised as far as refers to the commercial aspect of the enterprise, he nevertheless accomplished a great feat, and to the day of his death he contended that the time would surely come when electricity would be economically used as a motive power upon railways.

Ever since Dr. Page's memorable experiment, thoughtful people have been looking expectantly and anxiously forward to the fulfilment of his prophecy. The time is now ripe for such fulfilment. In fact, it has even now passed from the stage of speculation and become *au fait accompli*, many miles of electric railway, notwithstanding their primeval crudity, now being in successful operation on a commercial scale in different parts of the world.*

You ask, I imagine, "What has rendered possible at this day that which was thirty years back demonstrated impracticable; and in what respect does the *modern* electric railway differ from that of the past?"

My answer is: that which has rendered the electric railway commercially feasible, is the discovery by Messrs. Varley, Siemens, and Wheatstone, and the subsequent development by many others, of the dynamo-electric machine; and the further discovery or demonstration by MM. Fontaine and Gramme of the reversibility of that machine, which admits of its being transformed into the most efficient form of an electric motor, when a suitable electric current is passed through it. The *difference* between the ancient and the modern electric railway consists in the fact that whereas the effort was formerly made to use electricity as a *primary* motive power originating from the consumption of zinc and acid, we now use the electric engine or electro-dynamic machine as a *secondary* motor, and the electric current simply as a means of *transmitting* power procured from natural sources or previously generated by any of the known economic methods, if some natural source of power is not at hand. Such a system contemplates the establishment of a central fixed station, where large steam boilers and engines of the most economic type are erected and used to set in operation dynamo-electric machines, which generate powerful currents of electricity. These currents are in turn transmitted through a copper conductor running along the roadway, and, by means of a moving contact, they are taken up into the cars while the latter are in motion, and there passed through an electric engine or electro-dynamic machine, which operates to propel the cars. This idea of the generation by dynamo-electric machines of powerful currents of electricity at stationary points, and the transmission of these electric currents to cars while in motion for the purpose of effecting their propulsion, was first put into execution in 1879, by Dr. Werner Siemens and myself, both of us working independently and mutually ignorant of the other's doings. I constructed a small model, such as was within my limited means, and used the same to demonstrate a lecture on electricity delivered at the time in Colorado Springs, Colorado; about the same time Dr. Siemens exhibited a more extensive model at the Paris Exposition.

In my system the method of applying the power was very different from that adopted by Dr. Siemens, my only object then being to demonstrate the principle of electric transmission of power to a moving car for the purpose of propelling the same. On receiving news of the work of Félix and Chrétien at the sugar plantation at Sermaize, they having resorted to electricity as a source of power for ploughing, I was more than ever impressed with the value of the system and of the future which lay before it, and I accordingly began experimenting upon and studying the subject up exhaustively, going thoroughly into every detail.

Although at the time actively engaged in medical practice, and connected with the Medical College in Denver, so great were the allurements, I was induced to give everything up in Colorado and leave there rather precipitately for Washington, in quest of a generic claim upon this fundamental principle. My case being examined, it was, however, found that the same principle had been *proposed* and provisionally patented, although not put in operation or even demonstrated and made public, as far back as 1840, by one Henry Pinkus, a remarkably inventive genius of that period. In 1840, however, the dynamo was unknown, and the electric car motors of Pinkus, which existed only in his imagination, were *supposed* to be operated by galvanic batteries buried in the ground. The principle of the transmission of the current to the car while in motion for the purpose of effecting its propulsion was, however, the same. The inventor even went so far as to anticipate the future use of "mechanical generators, which should be more economical" than the batteries.

Dr. Siemens and myself are consequently antedated as regards the question of first conception of this broad principle, and the underlying feature of the *modern* electric railway becomes public property. My application for a patent upon this fundamental principle is a matter of record in the United States Patent Office. This application was abandoned on discovering the record of the Pinkus patent. Appreciating, however, the rich harvest in store for inventors in this new field who should devise the most practical and economical means of applying this principle, which comprehends an army of important details, I immediately began research into the necessary conditions to a successful solution of this most intricate problem. The results of this investigation, which has cost many thousands of dollars, will, I hope, in your judgment, prove meritorious.

We may, of course, crudely mount upon a car a dynamo-electric machine of our own or another's design, and connect this up with the wheels or axles of the car by means of cog-wheels or belting, and thus effect the propulsion of the car, temporarily for exhibition purposes, regardless of the cost or of practical commercial requirements; as several have done since the first public exhibition of the modern electric railway by Dr. Siemens and myself, the individuals in each instance styling the result as "their electric railway," which, as a matter of fact, differed, figuratively speaking but by a bolt or a nut from Siemens's original road.

(TO BE CONTINUED.)

* Page's motor in operation and stereopticon views of the others were here introduced.

COMPANIES' MEETINGS.

Special Meeting of the Compagnie Internationale des Telephones.

The special genera. meeting of shareholders in the above Company, called for deciding as to its reconstruction, was held at Brussels on 18th Dec., when M. Ed. Duchâteau, President of the Administrative Council, occupied the chair. The meeting was largely attended, about 49,000 shares being represented. The Chairman set forth summarily the conduct of the Administrative Council during the last period of its management of affairs, and called upon the shareholders, before discussing the measures which would terminate the Council's mission, to formulate an expression of their opinion as to the manner in which that body had discharged its duties. The following resolution was adopted by 26,152 to 4,588 votes (the administrators, who represented 15,025 votes, abstaining):—"The general meeting, after hearing the explanations of the President of the Council, formally approves of all the administrative acts hitherto performed by that body, and passes to the order of the day."

After the reading of the Council's report, the first resolution was adopted by 44,587 votes to 2,178:—"The following paragraph is added to Art. 29 of the Articles of Association: 'If the liquidator, duly authorised by the general meeting, brings as assets to another company the whole or a portion of the common property, and if he receives, as the price thereof, shares and promoters' interest in the new Company, the liquidation shall be effected, these promoters' shares being handed over to holders of sin ilar shares in the new Company, and the shares in the new Company, as well as the other bonds (*titres de portfeuille*) which might have been excluded from the assets brought to the new Company, being distributed among the shareholders, *pro rata* of the payments made.'"

The second resolution, carried by 42,603 to 1,637 votes, provides for the reconstruction of the Company in the following terms:—"The limited Company (Société Anonyme), known as the Compagnie Internationale des Téléphones, is disolved from this day, and will be wound up by a liquidator having the fullest powers, as determined by Articles 111, et seq., with power to constitute a company, and bring to it as assets all or a portion of the share property, in return for paid-up and promoters' shares, with power also to enter into all conventions for the liquidation of the liabilities, and to apportion the share capital in accordance with the terms of Article 29, as altered."

The third resolution appointed M. Adlerstein as liquidator, and M. Coene as assistant liquidator.

Australasian Electric Light, Power, and Storage Company (Limited).

The ordinary general meeting of the shareholders was held at the offices of the Company, 41, Coleman-street, on Tuesday, Mr. Latimer Clark, C.E., in the chair.

Mr. J. H. DUNCAN, F.C.A. (the secretary), read the notice convening the meeting, and also a letter from the auditors with regard to the stock in Australia, and in reply to a question, the Chairman said that the stock in Australia had been checked several times by the local auditors, and certified as being correct.

The CHAIRMAN said the shareholders would observe that the £3,000 which appeared as profit in the accounts from the Australian Company had not been treated as a profit. With regard to the £773 loss on Theatre Royal lighting installation, that contract had now been merged into a contract which was profitable, and they were writing that amount off at the rate of one-sixth every year; therefore they treated that £773 as a suspense account. He wished to explain why he occupied the chair to day. He was sorry to say that Mr. Want, who had hitherto so ably filled the chair, had found it necessary, from pressure of business, to resign the chairmanship, and in consequence he (Mr. Clark) had been requested to fill the chair to-day. He was sorry the report was not a pleasant one. There was no doubt the whole of the Company's large capital for payment of patents had practically turned out to be almost worthless upon the Company's hands. No doubt they all went into this enterprise at a moment of enthusiasm, the same as thousands of others did, under the impression that they were doing a good thing for themselves; but they had since learned that they had committed a great error. There was only one gleam of satisfaction, and that was that matters might have been very much worse. He himself applied for ten times the number of shares which were allotted to him, and he was glad they were not allotted; and if it had not have been for the enthusiasm which prevailed at the time, and the rush for shares, he should have had the whole amount he applied for, and should have been severely bitten for his pains. The Company expected to make a great fortune by the sale of concessions in Australia. At the time of the starting of this Company concessions for electric lighting could be sold for almost any sum, and it was thought that it was only necessary to send out concessions to Australia in order to sell them there. The Directors chose Sir Julius Vogel, whom they thought a competent man, who went out there, the Directors supposing that they would be able to sell the concessions freely. While Sir Julius Vogel was on his journey the whole bubble collapsed, and shares of these companies fell ruinously in price; and when Sir Julius Vogel reached his destination he found that telegrams had preceded him to Australia, telling the Australian people of the difficulties in this country. Sir Julius Vogel tried to sell concessions, but failed. The Directors pressed Sir Julius to form companies, and perhaps they pressed him too hardly, and he did form an Australian company, but arranged it in such a form that this parent company had to pay instalments on shares. Then he tried installations of electric lighting; in doing so they had incurred the greater part of the loss of £27,000. Sir Julius Vogel entered into contracts which the Company knew to be unprofitable, but which were intended to introduce electric lighting into Australia. As regarded the £27,000 to the debit of the Company, the shareholders must remember that if the Directors had chosen to "cook" the accounts, as it was commonly called, it would have been easy to make that loss appear less, because the greater part of that was really in the nature of advertising, and it would have been a justifiable thing to charge it to capital account, because it was really a case in which they had spent money in advertising the business. He wanted to divide the subject into two halves. He had referred to the past, and nothing could be more gloomy than that; but there was also the future, and he wanted to impress on their minds that the two were very distinct things. Everything had hitherto been against the Company. The Directors had written down everything to the lowest point, whereas they might have written much of it to a suspense account. But now he wanted to look to the future. The Directors, as regarded the future, still retained those hopes which they held last year when the shareholders were called together and their sanction obtained to an amalgamation with the Australian Electric Company. The Directors had many grounds for retaining those hopes. In the first place the business generally was reviving and was taking root rapidly, and, although not being executed by public companies, yet it was being executed by private firms to a great and profitable extent. The next point was that this Company was not bound to any particular system. The Company had paid enormous value for the Brush patents and also for the Sellon-Volckmar patent, but the Company was open to take up any other form of patent. Then, again, in Australia they had an excellent body of officers, and they had also a committee of management there, comprising three of the most influential men in Sydney, who were looking after the Company's interests there. The expenses in Australia were also being reduced. The accounts now presented were made up to June last, and up to that time they could not get all the contracts which had been made for the purpose of advertising and exhibition; but since then the Directors had been, and were still, getting rid of unprofitable contracts, and now they took in, and listened to nothing, which did not yield a profit. The Directors had placed in the hands of the shareholders a list of the works which had been executed. If they looked at the list they would find many losses and many profits. There was a heavy loss on the New Zealand contract; the other losses were temporary and were entered into for the purpose of illustrating the advantage of electric lighting. Therefore there were many matters for consolation. As regarded the Australian Electric Company, the accounts spoke for themselves. There was one great advantage which this Company had, and that was that the lighting had given great satisfaction in Australia, and there had been none of those breakdowns which had been heard of in this country. The Company had an excellent arc and incandescent light, and could do excellent lighting by both syetems. They had sent out a machine made by the Brush Company, and a Ferranti machine, which had worked with excellent results. There was no opposition to speak of. By amalgation with the Australian Electric Company they had done away with the opposition which compelled them to take these contracts at a loss. In Australia the expenses would be very different to what they appeared in the present accounts, and would in future be about £3,000 a year. The expenses in London would be about £1,500; therefore, in future the expenses would not be more than £4,500 altogether. The Directors had the strongest assurances from the agent on the other side that he saw his way, by business there, to meet expenses. If they earned £4,500 by the sale of £10,000 of plant, not only would they pay expenses, but also pay back some of the capital. They had £30,000 worth of plant in Australia, and if they could sell that they would get a considerable amount of money back. These were the chief features of the future. The Company was emerging from its heavy losses, and in the future the losses could not be of the magnitude and the kind which they now saw on the sheet before them. He could not congratulate them upon the position of the Company, but he thought the future was more hopeful than any one could suppose who merely took the balance-sheet and formed his opinion from that. They began with a large expenditure, under hopeful circumstances; the results were not what were expected, but he thought they had now been able to turn the helm and turn the Company's head towards port. In conclusion, the Chrirman moved the adoption of the report and accounts.

Mr. J. J. CATER seconded the motion, and said that negotiations had been going on for an amalgamation with the local Edison Company, and if this arrangement were carried out this Company would get rid of a formidable competitor in Australia, and their hands would be very much strengthened. He expressed his confidence in the future of electric lighting in Australia; he had never sold a single share in the Company, but had bought shares, which, at any rate, proved his belief in the undertaking.

Mr. STEPHENS, who said he was an original allottee, and the holder of 100 shares, moved that a committee of *bonâ fide* shareholders be appointed to inquire into and give a full and true account of the past history, present position, and future prospects of the Company, and also to ascertain whether by proper and economical management it was likely to succeed. He thought this should be ascertained before the remaining £1 per share was spent. As to the Directors, he had not that confidence in their management which would induce him to vote for their re-election.

Mr. BRANSCOMBE seconded the motion of Mr. Stephens. He asked for an explanation of the credited suspense account, £750.

Digitized by Google

Mr. WAINWRIGHT thought the expenses of the London office, £465, were two high. The item of miscellaneous expenses, £360, required some explanation.

Mr. VAN TROMP said he thought the Directors would do well to consent to the appointment of a committee (who would not necessarily be hostile to the Board), who would inquire what the real position and prospects of the Company were, and whether further operations should be stopped, or whether the remaining one-fifth of the capital could be profitably expended or not.

Mr. INCE pointed out that the money which had hitherto been expended had been very much in the nature of an advertisement. For his own part he could not see that the Directors had done anything but what they believed to be in the interests of the Company.

Mr. LABOUCHERE said that the Company seemed to be beginning to turn the corner, and it would be a mistake not to adopt the report.

Mr. VAN TROMP asked whether the Board concurred in the appointment of a committee.

The CHAIRMAN said he very much appreciated the manner in which he resolution had been brought forward, but at the same time the minds of the Directors were made up on the subject. The Directors were not in accord with the mover and seconder of the resolution on this subject; he had no objection to the appointment of a committee, but it must not be as a committee of inquiry. If a committee of inquiry were appointed the Directors would refuse to be re-elected. The Directors had already said they would welcome shareholders on the Board, or a small consultative committee, but not a committee of inquiry.

A SHAREHOLDER: Would such committee have power to present a report?

The CHAIRMAN: Certainly.

The SECRETARY said that, judging from what came from a certain quarter of the room, there seemed to be a body of shareholders acting together for a specific object. He merely wished to draw attention to the fact.

A SHAREHOLDER said he thought the Directors had done the best they could for the Company, though no doubt there had been errors in the past.

Mr. INCE suggested that the proposed committee should be appointed to confer with the Directors, and not as a committee of inquiry.

Mr. A. J. LAMBERT said no doubt the Directors would be prepared to give every assistance to such a committee as suggested by Mr. Ince. Such a committee could obtain all the information required quite as well as a committee of investigation, and it was infinitely better on all accounts to adopt the suggestion of the last speaker rather than to get into antagonism with gentlemen who had been conducting a difficult and, up to the present time, an unfortunate business.

Mr. STEPHENS said he would modify his resolution as follows:—"That a committee of *bonâ fide* shareholders be appointed to confer with the Directors as to the past history and present and future prospects of the Company, and to report to a future meeting of the shareholders."

Mr. RAY seconded the motion, and said there was no suggestion of *mala fides* on the part of the Directors, but the shareholders simply wanted the present position and future prospects of the Company inquired into.

The resolution of Mr. Stephens was then put and carried, and Mr. Van Tromp, Mr. Pearson, Mr. Ince, Mr. Kisch, and Mr. Stephens were appointed the committee.

The CHAIRMAN, in reply to questions which had been put, said the Board were considering the desirability of acquiring the local Edison patents; if they acquired them they would not have to pay anything in the shape of cash, as the Company would be assisted by the willingness of the vendors to part with a portion of shares for that purpose. As regarded the Directors' fees, they had been placed to a suspense account, and would not be paid till the Company proved a success.

The SECRETARY explained the items in the accounts regarding which questions had been asked.

Some discussion then ensued as to whether the report and accounts should be adopted, and in the end the proposition for their adoption was negatived by 12 votes to 9.

In reply to a question, the CHAIRMAN said: The present Board will retain office nominally till a fresh Board is elected. We shall take steps to call another meeting.

On the motion of Mr. INCE, a vote of thanks was passed to the Chairman, and the meeting then closed.

Brush Midland Electric Light and Power Company (Limited and Reduced).

An extraordinary general meeting of the shareholders in the above Company was held on the 24th of December, at the offices, 4, Great Winchester-street, under the presidency of Mr. R. H. Glyn.

On the motion of the CHAIRMAN, seconded by Lord GREVILLE, the resolution passed at the former meeting, approving a conditional agreement between the Company and the Anglo-American Brush Electric Light Corporation (Limited), was confirmed; as was also the resolution passed on the same occasion, for winding up the Company voluntarily, under the provisions of the Companies Acts, the Chairman proposing, and Mr. Harrington seconding this motion.

A resolution was next submitted by Mr. HARRINGTON for the appointment, as liquidator of the Company, of Mr. Emile Garcke (secretary of the Anglo-American Company).

Mr. WYGRAM having seconded the motion, it was agreed to.

The proceedings then terminated.

TESTIMONIALS.

From
Messrs. LEWIS OLRICK & CO.,
27, Leadenhall-street, London, E.C., Jan. 8th, 1884.

We have pleasure in stating that the two 16 H.-P. Engines you supplied in February of last year for the Edison Electric Light Installation at the Holborn Restaurant, have been working very satisfactorily.

We find that the Automatic Governor fitted to these Engines controls the speed very well indeed.

During the last few months they have been very severely tried, being worked considerably above the guaranteed power, and have not shown signs of undue wear.

From
Messrs. OLSZEWICZ & KERN,
Kieff, 1/13, Novr., 1884.

We have to express our most sincere thanks for the excellent performance of your two Engines, which were used to drive our Dynamo Electric Machines at the Odessa Agricultural and Industrial Exhibition.

These Engines were at work for five weeks driving one Incandescent and two Arc Machines, and we can state with pleasure that on account of their quiet and regular motion, as well as by the accurate and quick action of the Governor, they have proved themselves to be excellent Motors for Dynamo Electric Machines.

We shall not fail to employ your Engines in our Electric Light Installations as frequently as possible.

From
Messrs. J. H. HOLMES & CO.,
Newcastle-on-Tyne, Dec. 22, 1884.

In reply to your favour of the 15th, we have pleasure in reporting that the 6 H.-P. Portable Engine you supplied to us, specially fitted for Electric Light purposes, has given every satisfaction, and we consider it a very good Engine.

RANSOMES, SIMS, AND JEFFERIES (Limited) have also supplied their Electric Light Engines to—

NOTES.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ended 31st Dec. were £3,790.

SOCIETE GENERALE DES TELEPHONES.—The paid-up 375f. shares in this company stood at 385 on 29th December, but rose to 390 on 5th inst.

THE TELEGRAPH IN SPAIN.—The military telegraph system of Spain is about to be reorganised and extended, and the latest improvements adopted.

WORKS LIGHTING.—Messrs. Sharp, Stewart, and Co., Manchester, have decided to light their works by electricity. Mr. F. D'A. Goold will carry out the work.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts for the month of December were £1,738 against £1,473 in the corresponding period of last year.

LIGHTNING.—During a recent thunderstorm, the steamer "Easby," while off Wilson's Promontory, Victoria, was struck by lightning; but fortunately did not sustain much damage.

THE EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December, 1884, amounted to £53,036, and to £49,181 in the corresponding period of 1883.

TELEGRAPH INSTRUMENTS IN FRANCE.—It is stated that there are no less than 7,702 Morse instruments in operation in France, and that the Boudet instrument transmits 1,800 telegrams daily.

ELECTRIC LIGHT IN THE SKATING RINK.—Two Berlin skating rinks, one in the Karlstrasse, and the other in the Pionnierstrasse, are electrically lighted, the former on the Brush arc system.

LECTURES ON ELECTRICITY.—Two lectures on electricity have been delivered at the London Institution, Finsbury-circus, by Professor O. J. Lodge, of University College, Liverpool, to crowded audiences.

ASKABAD-MERV-SARRACKHS TELEGRAPH LINE.—The Russian Government is reported to have apportioned a sum of 100,000 roubles for the immediate erection of a telegraph line from Askabad to Merv and Sarrackhs.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 31st Dec. are £2,278, as compared with £2,314 in the corresponding period of 1883.

PARIS TELEGRAPH STAFF.—The number of lady clerks in the Bourse telegraph office, Paris, has been reduced; and it is thought that, by a judicious redistribution of duties, the work may be performed by two-thirds of the staff as now reduced.

ELECTRIC LIGHT IN THE HOSPITAL.—We learn that the wards of the new female hospital, Berlin, are lighted by 96 incandescent lamps, only 72 of which, however, are in action at one time, the motive power being supplied by a 9-horse steam engine.

ELECTRIC LIGHT IN HOLLAND.—It is reported that there is an idea of electrically lighting the Hollandsche Haafen, near Rotterdam, by means of accumulators. But why, in the name of common sense, by accumulators, instead of by current generated direct?

ELECTRIC LIGHT AT LANARK.—Permanent electric lighting arrangements have recently been made in the small town of Lanark, the business premises of Messrs. Hunter and M'Morrison, ironmongers, having been completely fitted up with incandescent lamps.

PLANTE ACCUMULATORS.—M. Planté has now made some accumulators in which the lead plates assume a horizontal position, and having a contact piece turned up at right angles. With this arrangement there is no difficulty in rolling, nor of the plates bending and coming into contact.

EASTERN EXTENSION, AUSTRALASIAN, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December, 1884, including all Government subsidies, amounted to £41,426, and to £35,335 in the corresponding period of 1883; increase, £6,091.

"L'ECLAIRAGE ELECTRIQUE."—At the ordinary general meeting of this company, held at Paris on 29th December, M. Hippolyte Fontaine, president of the Administrative Council, in the chair, the accounts were passed; and it was shown that the profits on last year's working amount to 185,587f. (£7,423).

ELECTRICAL MISSION.—The scientific men, including M. D. Napoli, M. G. Duché, M. A. Guerout, and M. Bertrand, sent by *La Lumière Electrique* on a mission to study electrical progress in various parts of the world, have returned to Paris, after visiting Canada and the United States, Mexico and the Antilles.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of December, 1884, amounted to £19,000. From 1st January to 31st December, 1884, they amounted to £276,280; in the corresponding months of 1883 to £254,488; and in the corresponding months of 1882 to £241,373.

APPLICATION OF STATIC ELECTRICITY TO THE HEALING ART.—The *Wiener Elektrotechnischen Zeitschrift* says that the Scientific Examining Committee of the late Vienna Electrical Exhibition talks of the application of static electricity to medical purposes; but the *Centralblatt für Elektrotechnik* asks how *static* electricity can be *applied* at all.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of December was 3,001, estimated to produce £2,500, against 2,774 messages, producing £2,559, in the corresponding month of last year. The traffic receipts for the month of September, estimated at £2,150, realised £2,163.

NEW BATTERY.—M. de Sainte Marie makes the positive pole of lead surrounded by chlorate of lead, and the negative pole of zinc, while the liquid contains chloride of lead, presumably for diminishing the resistance. Under the influence of the electric current, the chlorate of lead is reduced to metallic lead, which is deposited in the form of sponge.

THE EARTHQUAKES IN SPAIN.—A telegram from Naples states that Professor Galli, of the Observatory at Velletri, reports the interesting facts that at the time of the earthquakes in Spain almost continuous oscillations were registered by his new and very sensitive instruments, and that from the 28th ultimo to 3rd inst. no less than 200 shocks took place.

ELECTRICITY V. GAS IN SCHOOLS.—During the discussion, by the Paris Municipal Council, of the Primary School budget, a petition was presented requesting the Administration to study suppression of gas in the schools and colleges, and the adoption of electric light. If this is found impracticable, the petitioner, M. Lyon-Alemand, advises a return to oil lamps.

UNIVERSITY COLLEGE, BRISTOL.—The second term of the department of Experimental Physics at this college will begin on 16th inst., under Professor S. P. Thompson, D.Sc., B.A. Lectures and classes in Experimental Physics will be given to first, second, and third year students. The physical and

Digitized by Google

electrical laboratory is open daily, and also on Wednesday evenings.

INSTITUTION OF CIVIL ENGINEERS.—The new president of the Institution of Civil Engineers, Sir Frederick Bramwell, F.R.S., will deliver his inaugural address at the meeting of the society next week. Sir Frederick is also chairman of the Executive Council of the Inventions Exhibition, and it is understood that engineering inventions since 1862 will be the subject of his remarks.

ELECTROTECHNIC HANDBOOK.—In connection with the Munich *Centralblatt für Elektrotechnik*, Herr R. Oldenbourg, of Munich and Leipsic, is publishing, for the second year, his "Kalender für Elektrotechniker," a guide and handbook for electricians. The contents are arranged under the six heads of Mathematics, Mechanics, Physics, Machinery, Electrotechnics, and items of everyday use.

ELECTRIC LIGHT AT THE PARIS OPERA.—The number of electric lamps at the Opera House, Paris, has been increased to 32 Edison arc lights and 6 Cance arcs, the latter being placed inside the chandelier, so as not to dazzle the eyes of spectators, while giving a considerable amount of light. A trial of the additional lamps has given satisfactory results; and they will be brought into requisition at the first performance of "Tabarin."

TELEGRAPH TO THE FASTNET ROCK.—The steamer "Kangaroo," belonging to the Telegraph Construction and Maintenance Company, sailed from the Royal Albert Dock, London, on Saturday, having on board the cable which is to connect Lloyd's signal station on the Fastnet rock with the Postal Telegraph Office at Crookhaven, county Cork. The work of laying the cable will be carried out as quickly as the weather permits.

"BULLETIN INTERNATIONAL DES TELEPHONES."—This is the title of the successor to the *bulletin* of the Compagnie Internationale des Téléphones, which, like the company itself, has been reconstituted. Our contemporary is increased in size without changing complexion, so that it will, in all likelihood, not cease to be familiarly, but irreverently, designated the "P'tit Bleu." The editorial department declares categorically that the paper will maintain its strict impartiality.

ELECTRIC LIGHT IN THE RESTAURANT.—*L'Electricité* of last week illustrates, *more suo*, the newly opened restaurant of the Krasnopolski beer hall in the Warmse-straat, Amsterdam, brilliantly lighted by Edison incandescents enclosed in opal glass tulips. This system of lighting has replaced the Siemens arc, which was found intense enough, but not sufficiently steady. Now, adds our contemporary, a stay in the restaurant is a *vraie fête pour les yeux*, favourably disposing the *convives* to gastronomic joys, while affording them a *consommation* much more necessary to existence than the choicest viands and most refreshing beverages—viz., respirable air *à discretion*.

CONVERSION OF LIQUID INTO DRY BATTERIES.—According to Onimus, batteries containing solution of ammonium chloride, zinc chloride, &c., may be converted into dry piles by mixing these solutions with plaster of Paris and allowing the mixture to solidify. If mixtures of ferric oxide or manganese peroxide with plaster of Paris are employed, the electromotive force is slightly higher than with plaster of Paris alone, and when ferric oxide is used the battery quickly regains its original electromotive force when the circuit is broken. When the battery is exhausted the solid plaster is simply again moistened with the solution.—*Jour. Chem. Soc.*

THE CREIL EXPERIMENTS.—It appears from the work of M. Vivarez, on the construction of overhead electric leads, that the silicious bronze cable for transmitting the current from Creil to Paris will be 75 kilometres = 46½ miles long, and weigh 20 to 25 tons. The resistance will not exceed 100 ohms; and if the current be 20 amperes at 7,500 volts, the loss of energy due to the conductor will be about $\frac{100 \times 400}{10} = 4{,}000$ kilogrammetres = 50 horse-power. If the external resistance be half the total resistance, there will be a theoretical useful effect of 50 per cent. of the power absorbed by the generator.

LIGHTING SHOW ROOMS.—A part of the show rooms of Mr. T. Briggs, Leeds, is lighted by an arc lamp. This lamp displaces eighteen gas burners, each consuming 4ft. per hour, and gives a much better light than the old system. The lamp is worked by an "A" Gramme machine driven by the "Otto" gas engine at the works about 100 yards away. The current of eighteen amperes at forty-five volts is carried along overhead wires of silicium bronze. The actual cost, including gas, carbons, oil, &c., is 2½d. per hour, which is only slightly in excess of the cost of gas previously consumed. It is a fact worthy of note that this is the first arc installation used for shop lighting in Leeds.

LIGHTNING CONDUCTORS AT AMIENS CATHEDRAL.—After the storm, with globular lightning, which occurred at Amiens on 24th Feb., 1884, M. C. Decharme called attention to the defective state of the lightning conductors on the Cathedral. That for protecting the spire had no terminal point, two visible breaks in the continuity of the iron conductor, and insufficient earth connection, made by the simple prolongation of the conductor into the soil, which always remained dry. The Administration of Historic Monuments has now, however, had all the *paratonneres* overhauled and connected together by large copper conductors, put in communication with galvanised iron plates of considerable area, immersed in the water of two wells.

NEW ORLEANS.—The New Orleans Council Committee on Fire Department and Lighting has decided to accept the proposition of the South Western Brush Electric Light Company, for one year, to furnish 113 electric lights of 2,000 candle-power each, to burn all night and every night, for 16,019.56 dollars. This is stated to be the exact cost to the city of lighting by the gas and oil lamps which the electric lamps will displace. The Gaslight Company declares that it will charge the city for every gas lamp now in use, whether any of them will be replaced by the electric light or not. A proposition of the Gaslight Company to light the municipal buildings, furnishing 20-candle lights at 1 cent. per hour each, has been accepted by the committee.

OIL WORKS LIGHTED BY ELECTRICITY.—The Pumpherston Oil Company, near Uphall, N.B., having decided to light their premises, entrusted the work to Messrs. Henry Bennett and Co., Glasgow, who have fixed the necessary apparatus for five arc lamps. The dynamo is placed in the fan engine house, and is driven by the same engine as the fan, which has been fitted for the purpose with a sensitive governor. The lamps are hoisted on poles 45 to 50ft. high, and the total length of circuit is about 750 yards. One lamp lights the "tip" for the burnt shale, another the retorts, a third at sulphate house lights the surrounding place, a fourth is placed so as to command the stills, and a fifth the space adjoining the refinery, including a range of steam boilers. The lights enable the outdoor work to be carried on all night as well as in daylight.

Digitized by Google

UNIVERSITY SCIENCE LECTURES.—The following are among the courses of twelve weekly lectures which will be given in connection with the London Society for the Extension of University Teaching during the January to April term :—Dr. J. W. Waghorn, R.M.D.Sc., will lecture on "Light," at Whitechapel, and on "Electricity," at the Bank of England and New Cross; Mr. F. W. Rudler, F.G.S., on "Geology," at Croydon; and Mr. Walter Pye, F.R.C.S., on "Human Physiology," at Blackheath and Whitechapel. The lectures are accompanied by class teaching, and an optional examination (in writing) is held at the end of each course by independent examiners, appointed by a joint Board of the Universities of Oxford, Cambridge, and London. On the results of this examination the Universities' Board awards first and second class certificates.

ELECTRIC POWER AT THE LOUVRE.—Most visitors to Paris know that, if they purchase goods to a certain amount at the Magazins du Louvre, they receive a small india-rubber balloon, stamped with the word "Louvre," which serves the double purpose of amusing the children and advertising the said gigantic drapery establishment. Now, the air-pumps, which inflate the hundreds and thousands of balloons, require a certain amount of power; and the many sewing machines, a still greater amount. For these two purposes, the Compagnie Electrique has installed one of their No. 5 generators, with a No. 5 normal motor for driving the sewing machines, and a No. 3 motor for the air-pumps; and at the branch establishment in the Avenue Rapp, a generator and two motors have been put down for driving the sewing machines. The *Bulletin International des Téléphones* says that the working leaves nothing to be desired.

PAROD'S ACCUMULATOR.—In the accumulator of M. Parod, the plates, instead of being simply composed of lead sheets, like those of Planté, contain a copper core, hermetically enclosed in a leaden cover, which constitutes the secondary plate proper, and which alone comes in contact with the exciting liquid. In the middle of this core, which is a good conductor, the primary current unites, simultaneously, all the secondary plates, every portion of which develops an equal electro-galvanic action. The absorption of the primary current is therefore excessively rapid and regular, and the formation uniform. These secondary plates with conducting core, which are capable of any form and arrangement, are contained in a cell of ebonite or other similar material, divided into two parts by a porous diaphragm, in such a manner as to avoid the oxidation of the electrodes and the transposition of the salts.—*Il Giorno, Rivista dell' Elettricità.*

ELECTRIC LIGHT AT THE ANTWERP EXHIBITION.—With respect to our note of last week, the general secretary writes us that it is not desired that one system only shall be shown; but, on the contrary, the Special Committee formed to study the question of lighting the palace and grounds, are en leavouring to get representatives of the various systems known to compete for the illumination of an area not less than 115,000 square metres in extent. Electrical engineers and electric lighting companies, English included, are invited to make offers for lighting various portions, so as to give an opportunity for judging of the merits of each. Side by side with the applications of the latest improvements in electric lighting, it will be very interesting to see the improvements that the gas companies have been compelled to make in order to fight their triumphant enemy. The Special Committee aforenamed will also admit any other system of lighting, perhaps better suited for certain cases.

POWER IN SWITZERLAND.—*La Lumière Electrique* reports that, at the town of Bienne, in Switzerland, near which the waterfalls are capable of yielding a power equal to that of several thousand horses, two dynamos, connected by an overhead line, consisting of two 7mm. copper wires, are installed, one near the fall and the other in the town, a distance of 1,250 metres, or nearly a mile. The generating dynamo is driven by a turbine, which also serves to set in motion some neighbouring machinery, while the receiver supplies current to two works requiring very different powers. In one, where silver is rolled, the power required is very variable; while in the other, where parts of watches are made, a uniform speed is absolutely necessary. A compound winding of the electrical machine has therefore been adopted, so that the speed remains constant whatever be the power required. The installation was effected by Meuron et Cuénod, of Geneva, with Thury dynamos, and has worked regularly for nearly a year.

THE TELEPHONE IN PARIS.—The *Pall Mall Gazette* says that New Year's Day in Paris witnessed the inauguration of an important postal reform, five telephone bureaux being opened at well-chosen centres of business or population. The Bank was necessarily the most important, and the office of the Grand Hotel gave the greatest facilities to strangers; but Parisians in all directions could avail themselves of the offices temporarily opened near the Madeleine, in the Rue de Grenelle, on the Boulevard Malesherbes, and in the great centre of the Halles, the use of these offices not being restricted to subscribers. The public had access to all of them, and the scale of payment was fixed by time, half a franc securing five minutes' uninterrupted conversation, with the privilege of rateable protraction of the time. It is proposed to forthwith increase the number of offices, so that the more important telegraph offices in the city shall be put in communication; in fact, the telephone will be made complementary to the pneumatic post.

TRAIN HEATING BY ELECTRICITY.—Referring to our recent note on this subject, we glean some more detailed information from the *Bul. Int. des Tel.*:—In this system, devised by M. Em. Courcelles and M. Alph. Elu, the heat is produced by the current passing through a certain number of small lead plates arranged transversely in an ordinary foot-warmer. The plates are all in a shunt circuit, the current, led by two iron wires, being thus evenly distributed. In the trials which took place at M. de Meritens' works, the current was generated by a Gramme machine and traversed five foot-warmers, 1·8 metre long, 22cm. wide and 5cm. thick (71 × 9 × 2in.) coupled in series. The current was 50 volts at 24 amperes at the terminals of the dynamo, so that the energy given out was about 1½ horse-power per second. Consequently, *le jeu ne vaut pas la chandelle*; but in another arrangement, patented by M. Thommasi about a year ago, the current passes through spiral metallic conductors in each foot-warmer, previously filled with some substance possessing great latent heat on melting, such as crystallised acetate of lead or hyposulphate of soda, and plunged into boiling water before starting.

TOMMASI'S HEAT INDICATOR.—For giving warning automatically of any undue heating in an electric conductor, M. Tommasi has invented an instrument consisting of a wooden block with cylindrical hole, fitted with a spiral spring, which supports a small copper cup, filled with stearine or paraffin. A short copper wire is bent angularly so as to project above the cup, the part which projects resting on the stearine, but in its absence on the cup, thus making contact. The short copper wire is put in the circuit by two binding screws, one of which, as also the spiral spring, is connected with an interposed bell, in a local circuit with separate battery. Between the two binding screws and above the instrument is

Digitized by Google

an incandescent lamp with coloured glass, which is switched into a shunt circuit, and also connected with the metal cup. The instrument is placed near the dynamo, and the bent copper wire is interposed in one of the leads near its junction with the machine. When the temperature of the lead reaches 60° C. = 140° F., the copper wire melts the stearine and makes contact with the cup, closing the bell circuit, and also that of the incandescent lamp, thus giving two warnings, one to the sight and the other to the hearing.

Electrical Conductivity of Weak Saline Solutions.—The electrical conductivity of the salts dissolved in water varies with the degree of concentration in a very complex manner, and differs between one salt and another, there being no general law or empirical formula of any considerable application. At first sight it might be conceived that this conductibility depends both on the chemical nature of the salt, on the hydrates which it is capable of forming, and on their stability. Experience also establishes the fact that it is not unconnected with some of the physical properties of the solution, and especially with its degree of viscoscity; but the precise proportion of these various influences has not yet been determined. It appeared to M. E. Bouty that there was reason, in the first place, to simplify the problem by only dealing with solutions having identical physical properties. He therefore experimented with solutions so diluted that their density and their viscoscity were the same as those of pure water, while their conductivity was relatively enormous as compared with that of water, being easily measured by an electric method founded on that of M. Lippmann.

Measure of Intense Light.—Before the Paris Academy of Science, the other day, M. A. Crova dealt with the photometric value of an intense focus of light (solar or electric), the determination of which, he considers, requires the practical realisation of the following conditions:—(1) Comparison of two lights of different tints; (2) valuation of the tint by means of a numerical factor; (3) determination of the photometric ratio of a very intense source as the function of a relatively feeble standard. The first condition may be realised by using a solution of perchlorate of iron and chlorate of nickel, across which the photometric screen is observed. In practice, the tint may be represented by means of two successive photometric determinations: one, obtained by observing Foucault's photometric screen through the solution 580, gives the ratio of the intensities; and the other, made by placing before the eye a glass reddened by oxide of copper, which lets pass radiations comprised between 726 μ and 752 μ, with a maximum of 650 μ, gives a ratio so much inferior to the former as the tint of the light compared with the carcel flame is whiter. The quotient of the former determination by the second permits of distinguishing the tint, which is so much greater as the light is whiter. Lastly, the third condition may easily be realised by the use of a special photometer.

The Stock Exchange.—On Tuesday, a large number of invitations were issued to visit the new extension buildings of the Stock Exchange, and see an experimental lighting of the place by electricity. The lighting has been carried out by Messrs. Woodhouse and Rawson, who have made the most of the space at their command, so far as the machine room is concerned. We should, perhaps, apply a term to the apparatus not unknown in Stock Exchange parlance, and say it was completely "cornered." Two field boilers supply steam to two of Willans' high-speed compound engines, which drive two Elwell-Parker dynamos. A third dynamo is held in reserve, and can be driven by either engine. If necessary, either of the boilers can supply both engines, or at a push one engine will drive the dynamos; so that the machinery is really in duplicate, thus obviating the danger of a total break-down. The main hall of the new building, which is octagonal in shape, carries a dome 70ft. in diameter. On the cornices, at the spring of the dome, specially designed wrought-iron standards are placed. These standards carry Woodhouse and Rawson incandescent lamps of 50 candle-power. Besides the standards there are a few similar single lamps. Altogether seventy-six lamps light the hall, while in the settling room below are sixty-six lamps of 20 candle-power.

Magnetic Polarisation.—A transparent isotropic medium, placed in a magnetic field, rotates in the direction of the lines of force. Verdet has established experimentally that the rotation of the polarisation plane is proportional (1) to the intensity of the magnetic field, and (2) to the cosine of the angle made by the direction of the luminous rays with the lines of force of the field. On the other hand, M. Cornu has found the following law:—The mean of the speeds of propagation of the circular waves of inverse direction, separated by the magnetic action, is practically equal to the common speed v of these waves when the magnetic action is *nil*. From these two laws M. Cornu deduces the existence of a system of two eccentric spheres, the common axis of which is parallel with the lines of force of the magnetic field; one of the spheres corresponds with the circular waves *dextrorsum*, and the other with the circular waves *sinistrorsum*, whence he enunciates the following:—In an isotropic medium, placed in a uniform magnetic field, the two kinds of waves with circular inverse vibrations, which can alone exist, are propagated in accordance with spheres identical with the sphere of the wave of the medium in a natural condition, symmetrically displaced by the same quantity in the division of the lines of force. This magnetic displacement is proportional to the intensity of the field and to the electro-optic constant of the medium.

Electric Light in Paris.—The Paris Edison Company has put down combined arc and incandescent lighting plant, under specially favourable conditions, at the Magazins du Gagne-petit, in the Avenue de l'Opera, Paris. Though the work was only begun on 17th Nov., it was completed by the end of December. The incandescent system is naturally reserved for the rooms of moderate height, while the Cance arc lamps are employed in the larger spaces. The motive power is given by a 100-horse steam engine by Boudier, supplied with steam by two Collet boilers. All the dynamos are Edison's—two 200-lamp for the ordinary lighting, one 100-lamp for day use in the basement, and another 100-lamp machine in reserve—wise precaution. The present lighting is effected by 400 Edison and 10 Cance lamps; but 300 more lamps are shortly to be put up, and also two more dynamos. The 400 Edison lamps already fitted take the place of an equal number of 15-candle oil lamps, as the managers of the drapery establishment would never have the gas brought in, on account of the danger, but used colza lamps at nearly 3d. each an hour. The Edison lamps are arranged in separate circuits for illuminating respectively the ground floor, the *entresol*, and the four floors above, while another circuit includes the day lamps, and still another those on the staircase approached from the Rue des Pyramides. The arrangements for distributing the current are similar to those generally adopted by the Edison Company. The Cance lamps, put up by the Edison Company's engineers, and all in shunt circuit, are distributed as follows:—Four in the Avenue de l'Opera entrance, two in the dome above, and two in each of the side courts, one lamp being placed above another for simultaneously lighting the ground floor and the *entresol*.

ABUSE OF THE TELEGRAPH.—From communications we have received on the subject of our last week's note under this heading, it appears that we have been misunderstood. Of the general utility of the "tape system" we have no doubt whatever, and our loose reference to "a dozen different offices" where Stock Exchange prices are communicated by means of this ingenious automaton did not apply in the least to those places of business where the information was received as news and for legitimate purposes. The subject is being warmly discussed in the City articles of our contemporaries in the interests of the investing public. A correspondent in the *Financial News* of the 2nd January says, "This tape matter is not what it professes; it is a maglignant attack upon outside brokers in general, and the Exchange Telegraph Company in particular; it is as foolish in policy as it is treacherous in motive. Foolish in policy as regards the dealer, because, although some of the business outside is 'set off' and cleared outside, the bulk necessarily finds its way inside." And another correspondent says, "I believe that it was in 1872 that the Exchange Telegraph Company was started to give facilities to the public, in order that they might ascertain for themselves from an independent source the current prices of the moment. The company appear to have done that conscientiously throughout. The tape has acted as a safeguard upon the broker with his client, and it has had the same effect between the broker and the jobber, and that the investing public have been satisfied with it is undoubted." It has been put to us that the one real grievance of the Stock Exchange is that outsiders get information of all their dealings; but this is obviously to the benefit of the public, because previous to the introduction of the tape brokers and jobbers could make their own prices inside, while the official list did not show the current transactions during the day, but only the closing prices which any broker or jobber chose to put upon the Board. The tape, on the other hand, is an accurate record of the transactions going on all day, and therefore the public can see whether the prices at which their stocks were bought or sold correspond with the prices ruling during the day. Something might be done possibly to diminish the gambling in outside exchanges, but it is certain that if the Exchange Company had to give up supplying prices to outsiders, it would fall into other, probably worse, hands, and be done in a more reckless fashion.

THE "RIGHT O' WAY" FOR TELEPHONES.—Englishmen profess to live under the purest form of Republicanism, their Government being practically Liberal, yet in 999 out of every 1,000 of the people no firmer conservators are to be found in the world. Englishmen detest change, come it in what shape it may, whilst our cousins in America eagerly adopt any new scheme that offers that has a tendency to make the wheels of everyday life run more smoothly. The staid Teuton is really more progressive than the Anglo-Saxon, and our neighbours of France take more earnest interest in scientific inventions and improvements than do our own countrymen. Let us take, for instance, the telephone It is universally admitted to be the most wondrous invention of the age, adapted to all and every detail of private and commercial life; yet how bitter is the cry against the companies who are endeavouring to bring it into practical use!—the cry against overhead wires as being dangerous, unsightly, &c., blocking out the pure air (!) of our great thoroughfares, disfiguring our mansions, villas, &c., and so on. Yet the growlers admit that telephony will supersede the telegraph in the not distant future. The public little know the difficulties that the officers of the telephone companies to whom is entrusted the duty of obtaining the "right o' way" have to contend with. These gentlemen must possess a general versatility of character, with the courage of a bulldog, the suavity of a collector for missionary purposes, the meekness of the dove, a glib tongue, like unto that of a Dublin car driver, a good temper, and the stoicism of a police magistrate, able to keep a smiling face under insult, and be ready to enter into conversation on the general topics of the day. You would be perfectly astounded when told how heavily the companies were handicapped by the general public in their efforts to obtain leave to run over property. For instance, one of these "right o' way" officers had successfully run a distance, and only required one "consent" to complete the line from point to point. He had managed to win over the occupier of the house to his views, and the usual agreement was about to be signed, when suddenly the parlour door was thrown open, and a shrill female voice squealed out, "Don't 'ee do onything o' the kind, Garge, for we'll git up soom marnin' an' fend oorseles deed, an' the roof on the top o' us!" That line is still incomplete, for there was only one way to do so, and that way was *Whartonised* as above. The following replies received are of daily occurrence by "right o' way" officers to their request for permission to pass over or to attach fixtures to houses, &c.:—

"I disapprove of the system of overhead wires."

"I will not allow anything of the kind."

"Declines to allow any fixture."

"Sorry to say, for various reasons, cannot sanction any such arrangement."

"Most decidedly objects."

"Both myself and landlord have a great objection to overhead wires, and must therefore refuse."

"Would willingly permit the fixture being made, but was informed by a friend that the language used by the speakers was so foul that she was compelled to remove her children's bed room to a lower room until the fixture was removed."

"I won't do anything of the kind. Why, I was a settin' with a friend as keeps a pub in the east end—oon night, at harf-past twelve, it wor on a Sunday, too, when in busts his three kids, a'most a frightened to death, and says they couldn't get a wink o' sleep becos your dratted wires were carrying a lot o' blagard langwidge backards an' forrards."

"Would rather you placed it on some neighbour's house!"

"Most decidedly not."

"I distinctly decline to permit anything of the kind!"

"Tell him I refuse and don't want to see him."

"Being an invalid is compelled to refuse."

"Tenant willing, landlord refuses."

"Landlord willing, tenant refuses."

"Has a serious objection."

"Wife has a great terror of lightning."

"Wife is very nervous."

"I absolutely refuse."

"Will not allow anything of the kind."

This is honest—"Roof too old and dangerous, otherwise consent would be willingly given."

"Thinks he has not the power, but if he had he would not sanction proposed arrangement."

"Not for £500 per annum."

A merchant asked, "How is it that telephony makes so little progress in London?" and was rather staggered on being informed, "That he himself had given a practical reply by his refusal to allow an attachment being made to his residence," and was told that if every one did as he had done—thrown cold water on the request made for right o' way—telephonic progress would of a necessity make little headway.—"*A Practical Worker*," *in the Edinburgh Courant.*

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

On the Transmission of Energy through Wires by the Electric Current.

Consider the electric current, how it flows. From London to Manchester, Edinburgh, Glasgow, and hundreds of other places, day and night, are sent with great velocity, in rapid succession, backwards and forwards, electric currents, to effect mechanical motions at a distance, and thus serve the material interests of man.

By the way, is there such a thing as an electric current? Not that it is intended to cast any doubt upon the existence of a phenomenon so called; but is it a current—that is, something moving through a wire? Now, although nothing but very careful inculcation at a tender age, continued unremittingly up to maturity, of the doctrine of the materiality of electricity, and its motion from place to place, would have made me believe it, still, there is so much in electric phenomena to support the idea of electricity being a distinct entity, and the force of habit is so great, that it is not easy to get rid of the idea when once it has been formed. In the historical development of the science, static phenomena came first. In them the apparent individuality of electricity in the form of charges upon conductors is most distinctly indicated. The fluids may be childish notions, appropriate to the infancy of science, but still electric charges are easily imaginable to be quantities of a something, though not matter, which can be carried about from place to place. In the most natural manner possible, when dynamic electricity came under investigation, the static ideas were transferred to the electric current, which became the actual motion of electricity through a wire. This has reached its fullest development in the hands of the German philosophers, from Weber to Clausius, resulting in ingenious explanations of electric phenomena based upon forces acting at a distance between moving or fixed individual elements of electricity. It so happened that my first acquaintance with electricity was with the dynamic phenomena, and after I had read with absorbed interest that instructive book, Tyndall's "Heat as a Mode of Motion." This may explain why, when it came later to book learning regarding electricity, I had the greatest possible repugnance to all the explanations, and could not accept the electric current to be the motion of electricity (static) through a wire, but thought it something quite different. I simply did not believe, except so far as mere statements of experimental facts were concerned. This had its disadvantages; one can get on faster if one has sufficient faith—which we know moves mountains—to accept a certain hypothesis unhesitatingly as a fact, and work out its consequences undoubtingly, regardless of the danger of fixing one's ideas prematurely.

As Maxwell remarked, we know nothing about the velocity of electricity; it may be an inch in a year or a million miles in a second. Following this up, it may be nothing at all. In fact, it is only on the hypothesis that the electric current is something moving, a definite quantity in a given space, that we can entertain the idea of its possessing velocity. Then, the product of its hypothetical density into its velocity is the measure of the current; but, being a mere hypothesis, unless we choose to accept it, to talk of the velocity of electricity in the electric current becomes meaningless. On the other hand, when we apply the ideas of abstract dynamics to electricity, and compare the electric current to a velocity, it is not the above suppositious velocity of electricity that is referred to in any way. It has no meaning. It is the supposed velocity of electricity in the electric current; whereas, in the dynamical theory, it is the electric current itself that is a velocity, in the generalised sense, with electromotive force as the generalised force; so that force × velocity = activity. In only one sense do I think we can speak of the velocity of electricity, consistent with Maxwell's theory, viz., by the hypothesis that the electric current in a wire is the continuous discharge of contiguous charged molecules, when plainly we can call the velocity of motion of a molecule the velocity of the charge it carries. As between the molecules we have the electric medium the ether, this view of the conduction current ultimately resolves itself into "displacement" currents in a dielectric.

But is there not the fact that we can send a current into a long circuit, and that it plainly travels along the wire, taking some time to arrive at the other end? Does that not show that electricity travels through the wire? To this I should have answered formerly, when filled with "Heat as a Mode of Motion," is it not a fact that there is a transformation of energy in the battery, and that this energy is transmitted through the wire, there suffering another transformation, viz., into heat; that when the current is set up steadily, the heat is generated uniformly; that the electric current in the wire is therefore some kind of stationary motion of the particles of the wires, not exactly like heat, but having some peculiarity of a directive nature making the difference between a positive and a negative current; but that there was no evidence in the closed circuit of any motion of electricity through the wire, but only of a transfer of energy through the wire.

However, leaving personal details of no importance to anyone but myself, let us consider the transmission of energy through a wire. How is it done? Knock and it shall be opened unto you? No, not exactly; but we may get a peep through the door "on the chain."

To fix ideas, let our circuit be an insulated suspended wire from London to Edinburgh, and that we transmit energy to Edinburgh from a battery in London, the circuit being completed through the earth. Let the current be kept on. In the first place the phenomenon is steady. It does not change with the time. Next we find that the magnetic force about the wire is the same everywhere at the same distance, or the wire is in the same condition as regards the magnetic induction outside it, and when we apply our knowledge to the interior of the wire regarded as a bundle of smaller wires, we find that the magnetic force *in* the wire does not vary along its length. Again, heat is being generated within the wire at a uniform rate (a part of the steadiness above mentioned), and, next, this phenomenon is also the same all along the wire. Heat is undoubtedly a kinetic phenomenon, hence the electric current is also, at least in part, a kinetic phenomenon. The electric current is not itself heat; but as its existence in the wire involves the continued production of heat, we conclude that some kind of motion is necessarily involved in the electric current apart from the heat produced, and from the uniformity of effect in different parts of the wire, that it is a kind of stationary motion. Again, the electric force is the same all through the wire. There seems no difference between one part and another. Outside the wire, in the dielectric, however, there is a difference, for the electric force varies not only at different distances from the wire but also at the same distance outside different parts of the wire. (We disregard here all irregularities due to other conductors and currents.)

Passing to the battery, the complexity of conditions makes it more difficult to follow, though the state of electric force and magnetic force and heat generation is reducible to the same, and may be made identically the same as in the wire by properly choosing its shape, &c. But in the battery there is a very remarkable thing taking place, namely the loss of chemical energy at a steady rate, and in the system generally, a still more remarkable thing, an exactly equivalent steady gain of heat. Heat that might have been produced on the spot by the chemical action otherwise conducted appears all over the circuit. How does it get there? The natural answer is through the wire. But to get to the further parts of the wire it must go through the nearer, hence there must be what we may call an energy current, which, in the wire, at a given place, would be the rate of transfer of energy through a cross section there. Now, which way is the energy current directed? It would seem only fair to let it go both ways equally from the battery; Let it be so, first. Then there is an energy current entering the wire equal to one-half the dissipativity, which falls in strength regularly up to the middle of the wire, where it is zero. It falls in strength on account of the heat generation.

Digitized by Google

Similarly the other energy current goes through the earth to Edinburgh almost unabated in strength, and is then directed from Edinburgh to the middle of the wire, where its strength also falls to nothing. This seems absurd. Then let the energy current be directed one way only, say with the positive current. If the positive pole of the battery is to line, we have an energy current in one direction all round the circuit, London to Edinburgh, and back through earth. If of maximum strength at the battery it falls nearly to nothing at the distant end, and quite to nothing through the earth up to the other pole of the battery. But we have no data whatever to fix whereabouts the place of maximum energy current is. It requires a second assumption. The reader may similarly consider the effect of reversing the battery, or of making the energy current be directed with the negative current. There is no getting at anything definite, except that the energy current must vary very widely though regularly in strength, whilst there is nothing to fix which way it is directed or where the maximum strength is. Again, the energy current is a kinetic phenomenon, and as it varies so enormously in different parts, we might expect different parts of the wire itself to be in different electrical states, which is exactly what we do not do, for though its potential varies, yet potential is not a physical state, but a mere scientific concept.

Had we not better give up the idea that energy is transmitted through the wire altogether? That is the plain course. The energy from the battery neither goes through the wire one way nor the other. Nor is it standing still. The transmission takes place entirely through the dielectric. What then is the wire? It is the sink into which the energy is poured from the dielectric and there wasted, passing from the electrical system altogether. All difficulties now disappear.

That the energy of the battery passes into heat immediately would require its instantaneous transmission to all parts of the wire, which cannot be entertained. There must be an intermediate state or states, after leaving the battery and before becoming heat. And there must be a definite amount of energy in transit at a given moment; in the steady state this must be of constant amount, just as the total rate of transmission is of constant amount. We must not, however, individualise particular elements of energy, and follow their motions, but regard the matter quantitatively only. The energy in transit may be compared to the energy of a machine which is transmitting motion; if done at a steady rate, it remains constant and definite, and the rate of transmission is definite.

Now in Maxwell's theory there is the potential energy of the displacement produced in the dielectric parts by the electric force, and there is the kinetic or magnetic energy of the magnetic induction due to the magnetic force in all parts of the field including the conducting parts. They are supposed to be set up by the current in the wire. We reverse this, the current in the wire is set up by the energy transmitted through the medium around it. The sum of the electric and magnetic energies is the energy of the electric machinery which is transmitting energy from the battery to the wire. It is definite in amount, and the rate of transmission of energy (total) is also definite in amount.

It becomes important to find the paths along which the energy is being transmitted. First define the energy current at a point to be the amount of energy transferred in unit time across unit area perpendicular to the direction of transmission. As the present section is argumentative and descriptive only, we cannot enter into mathematical details further than to say that if H be the vector magnetic force and E the vector electric force, not counting impressed forces, the energy current as above defined is $VEH/4\pi$ (see equation (3) for definition of V.) This is true universally, irrespective of the nature of the medium as to conductivity, capacity, and permeability, or as to eolotropy or isotropy, and true in transient as well as in steady states. A line of energy current is perpendicular to the electric and the magnetic force, and is a line of pressure. We here give a few general notions.

Return to our wire from London to Edinburgh with a steady current from the battery in London. The energy is poured out of the battery *sideways* into the dielectric at a steady rate. Divide into tubes bounded by lines of energy current. They pursue in general closed paths in the dielectric and terminate in the conductor. The amount of energy entering a given length of the conductor is the same wherever that length may be situated. The lines of energy current are the intersections of the magnetic and electric equipotential surfaces. Most of the energy is transmitted parallel to the wire nearly, with a slight slant towards the wire in the direction of propagation; thus the lines of energy current meet the wire very obliquely. But some of the outer tubes go out into space to an immense distance, especially those which terminate on the further end of the wire. Others pass between the wire and the earth, but none in the earth itself from London to Edinburgh or *vice versâ*, although there is a small amount of energy entering the earth straight downwards, especially at the earth "plates." If there is an instrument in circuit at Edinburgh, it is worked by energy that has travelled wholly through the dielectric, then finding its way into the instrument, where it enters the coil and is there dissipated, or else used up by the visible motions it effects in moving parts of the instrument; which, however, is a different kind of affair from dissipation, as it involves impressed force.

Now go into the line wire. A tube of energy current arriving at the surface of the wire by a long slant, at once turns round and goes straight to the axis. In passing from the battery to the wire through the dielectric the energy current is continuous, the state being steady (or the ether machinery frictionless); but directly it reaches the conducting matter of the wire dissipation commences and the current begins to fall in strength, and on reaching the axis has fallen to nothing. Not a fraction of an erg is transmitted along the wire. Some small part of the energy leaving battery may enter it again, but most of the dissipativity in the battery itself is accounted for by the weakening of strength in tubes which are on their way to leave the battery.

Put the battery in the middle of the line; earth at both ends. Now, one half of the energy current tubes leaving the battery sideways turn round to one section of the line, the other half to the other section. Otherwise the case is similar to the last.

When we have a double wire looped without earth, and battery at one end, most of the energy is transmitted between the wires.

In a circular circuit, with the battery at one end of a diameter, its other end is the neutral point; the lines of energy current are distributed symmetrically with respect to the diameter.

On closing the battery circuit there is an immediate rush of energy into the dielectric, and, at the first moment, into all bodies in the neighbourhood of the battery, and wasted there in induced currents according to their conductivity. In the variable state the tubes of energy current are themselves in motion. It takes some time to set the electric machinery going steadily. Also the energy current is not continuous in the dielectric, for the potential energy of displacement and the magnetic energy have to be supplied at every place. But in the end the energy current becomes continuous in the dielectric, goes round an external conductor instead of entering it, as it would do in the transient state, and finally reaches the conductor to which the battery is connected, penetrating which it terminates.

If we neglect the magnetic energy, as in Sir W. Thomson's original telegraph theory, against the energy of electric displacement, we can easily get a general idea of the setting up of the permanent state in a long suspended wire; a submarine cable is more complex on account of the sheath. The energy reaches the beginning of the wire first, and only reaches the end, save insignificantly, later on. But the theory indicates instantaneous setting up of current at the far end, though not in recognisable amount. This result follows from the neglect of the magnetic energy. In a dielectric medium the velocity of undisturbed propagation is $(c\mu)^{-\frac{1}{2}}$; c the capacity, μ the permeability; the magnetic energy $=0$ is equivalent to $\mu=0$ everywhere, whence instantaneous transmission. The "retardation," however, arises from the setting up of the potential energy of displacement. But strictly speaking, we must not

Digitized by Google

neglect μ. It is, then, not so easy to follow the transient state without simplifications. There is an oscillatory phenomenon in the dielectric, a to and fro transmission of energy and pressure parallel to the wire all round it with a velocity whose possible maximum is that of undisturbed transmission. This is modified as it progresses by dissipativity in the wire, and so gets wiped out. This usually occurs so rapidly that the oscillations are of importance only at the battery end of a long wire. The electric machinery must have mass, as well as elasticity, by reason of this phenomenon, since there is reason to believe (Maxwell's theory of light) that it is not the air, but something between the air molecules that is the electro-magnetic medium, the air merely modifying the phenomena somewhat.

In the state of steady current through a submarine cable, with an iron sheath outside the dielectric, the energy is transmitted wholly through the gutta percha or other suitable insulator (neglecting the small amount going to earth), thus nearly parallel to the wire, practically quite parallel, except as regards the lines near the wire itself, as they all eventually meet the wire. No transmission in the sheath, though there is dissipativity there if it should contain, as it does sometimes, part of the return current. In the transient state there is of course always dissipation in the sheath more or less, besides the loss of energy to magnetise it.

Now to speak more generally. In the steady state of current due to any impressed forces, the tubes of energy current start sideways from the places of impressed force, where energy is supplied to the electric system, and travel through definite paths, without loss in dielectric, with loss in conducting parts, to terminate finally in conducting matter; or else they may go from one place of impressed force to another with or without dissipation on the way when the current is with the impressed force at one source, and against it at the other. But with special arrangements (solenoidal) of impressed force, there is no transmission of energy in the steady state.

Since on starting a current the energy reaches the wire from the medium without, it may be expected that the electric current in the wire is first set up in the outer part, and takes time to penetrate to the middle. This I have verified by investigating some special cases.

Increase the conductivity of a wire enormously, still keeping it finite, however. Let it, for instance, take minutes to set up current at the axis. Thus ordinary rapid signalling "through the wire" would be accompanied by a surface current only, penetrating to but a small depth. The disturbance is then propagated parallel to the wire in the manner of waves, with reflection at the end, and hardly any tailing off. With infinite conductivity there can be no current set up in the wire at all. There is no dissipativity; wave propagation in the medium is perfect. The wire current is wholly superficial, an abstraction, yet it is nearly the same with very high conductivity. This illustrates the impenetrability of a perfect conductor to magnetic induction (and similarly to electric current), applied by Maxwell to the molecular theory of magnetism. Whatever state of magnetic induction and of current there may be in a perfect conductor is a fixture. If we move the conductor about in a magnetic field, superficial currents are instantaneously induced, whose only function is to ward off external induction and keep the interior state unchanged.

In a thermo-electric circuit of two metals with one junction a little hotter than the other, there is a transmission of energy from one junction to the other through the dielectric, with a trifling amount of loss in the circuit generally. Here the source of the electric energy is heat, and the final result is heat. One junction is cooled, the other is heated, reversibly. Now, heat is the energy of molecular agitation, and at first sight the only difference is that the agitation is a little more brisk at one junction than at the other. Again, all parts of the circuit are agitating the ether. It would appear, then, that the ordinary molecular agitations set up no electric manifestations on account of their irregularity; although the electric machinery may be influenced vigorously, yet it must be done in some regularly symmetrical manner to constitute an impressed electric force. At the junctions there is a change of material, the molecules are different, and at their contact some directed quality is given to the agitations. This is very vague, no doubt, but is merely to point out that the impressed force is a symmetrical kind of radiation.

After these general remarks the temporarily interrupted mathematical treatment will be resumed.

(TO BE CONTINUED.)

PROFESSOR TYNDALL ON THE SOURCES OF ELECTRICITY.

The first of a course of six lectures adapted to a juvenile auditory by Professor Tyndall, on "The Sources of Electricity," was delivered, on Dec. 27, at the Royal Institution, Albemarle-street, Piccadilly.

Professor TYNDALL, in opening the course, said he knew that the delivery of such lectures caused pleasure to others besides himself. It was a pleasure to his colleague, Professor Dewar, and to their noble and good master, the late Professor Faraday, who in the later years of his life lectured to no one else but to those whom he loved to call the juveniles. Nine years ago he (Professor Tyndall) undertook to lecture upon the subject of electricity to boys and girls in that institution. At that time he took what he now called friction electricity, and he devoted the whole of the six lectures to that subject. His intention now was to give them a connected story, so to say, from beginning to end—commencing with the smallest germ, and showing them how it grew up until it had reached the development of the present time. Many of them were aware that the name of this electricity was derived from the fact that first facts were observed by the ancients in the attraction of light bodies by amber. Amber was called, as many of them knew, electron—hence the name electricity, that was, that wondrous power of attraction which amber at first exhibited. It might be mentioned that amber was still found in various parts of the earth. It was found in Europe, especially on the shores of the Baltic, particularly after storms, when it was cast upon the waves, and gathered there. There were also beds of fossil trees. In point of fact, along the shores of the Baltic the amber tree in distant times bloomed; and just as the poplar at the present time oozed out its gum, or the pine tree its resin, so the amber tree in those days dropped its precious gum into the sea; and where the amber had fallen and could be converted into lignite, they there found the amber diffused among the fossil amber trees. The ancients had another story about amber. They considered it a very costly ornament, and paid dearly for it; and, indeed, at the present time, the revenue derived from the sale of amber is very considerable. The ancients told them that the daughters of the sun, for some reason, were converted into poplars, that these poplars wept tears at their sufferings, and that these tears, petrified, became amber. They would find the account in Sir George Cornewall Lewis's History of Ancient Astronomy. He would begin with the first experiment made with amber. He held in his hand a piece of amber made into the form of a stick consisting of the two mouthpieces of pipes fused together. By means of this stick he would show them the attraction of light bodies by amber. Rubbing the amber with catskin, he showed how some bran was attracted by the amber. [Experiment.] The human mind was never contented with merely looking at a thing and seeing that thing occur; they were never contented with facts. Therefore, at an early time, the question occurred, Why did amber attract light bodies? The ancient philosopher was following the irresistible profundity of the human mind when he asked the reason of this. He supposed the amber to possess a soul, and in virtue of this soul attracted these light bodies. This was the theory of the celebrated Newton, the great astronomer and philosopher. There were various other ways of showing this attraction. For instance. [Experiment.] He placed a lath upon a point, and showed how a glass tube, after being rubbed, as he had rubbed the amber, acted upon the lath. He ought, however, first to have stated that this attraction of light bodies by amber was the only thing known to the human mind for 2,000 years. Not until the year 1600 was the bond pierced by the celebrated Dr. Gilbert in the time of Queen Elizabeth. Dr. Gilbert said, "If you look at amber it is a kind of gum. You see insects sometimes entangled in it. It would be very extraordinary if this were the only thing capable of attracting light bodies." Dr. Gilbert therefore set to work, and found a vast number of other substances attracting light bodies, like glass, for instance, in its action on the lath in the experiment he had shown. They might use sealing-wax instead of the glass tube he had used. The lecturer then, to illustrate this, showed several other experiments with a watch glass, an egg, a piece of sealing-wax, and a small wheel. He wanted to impress on them the quality of what was called a scientific mind. It had the quality of looking behind facts. They would observe in the experiment that

Digitized by Google

the wheel followed the glass tube about as a carriage followed the horses harnessed to it. The question which a scientific mind asked was, "Is there anything between the glass tube and the wheel?" That was a question which occupied the mind of the great Sir Isaac Newton as to gravitation. He asked himself, "How is it that the sun can control the earth in its orbit. He was too cautious to express any definite opinion on the matter, but his conclusion was that there was something there which enabled the sun to act upon the earth. In the same way he (the lecturer) now asked them this question—whether anything existed between that wheel and the glass tube? That question was one of the most important that occupied the minds of scientific men. They wanted to know whether there was a medium between that glass tube and that wheel. It was, as he had said, a point which was occupying the minds of scientific men, and perhaps they would not solve it in our day. Another experiment was made with regard to attraction by Sir Isaac Newton, who was a great experimenter as well as a great mathematician, and he was very much taken by this electrical attraction. He made this experiment: He wore a dressing gown; he got a plate of glass and placed light bodies, such as bran, over that plate of glass, on which rested a ring of brass, placing over it a plate rubbed against his dressing gown. Projecting the shadow of the brass upon the screen, the lecturer showed this experiment, and how the bran was acted upon. Incidentally he drew attention to the arrangements he had provided for keeping out of the theatre all vapour and moisture, the arrangements being, he observed, to secure dryness, and not warmth or heat. Passing on to the laws of this attraction which they had just seen, he said he would give them an experiment which was first made by a sturdy old fellow, the burgomaster of Magdeburg, in Prussia, Otto Guericke, who invented the air pump. He noticed that when one brought an electrified body to and near a suspended feather one saw it attracted there. He noticed after it was attracted, and after it touched the attracted body, that it was repelled. [This experiment the lecturer then showed, using the glass tube before mentioned.] He might, he explained, use sealing-wax, or shellac, or a variety of other bodies. Showing how the feather was drawn towards a stick of gutta percha and driven away by a glass tube, he stated that in this exhibition they had the first notion of the difference between electricity on the surface of the glass and upon the surface of gutta percha. The one attracted, the other repelled the feather. He would now show them an experiment which he himself first made that morning, guided, of course, by the principles of electricity. They had seen him, he first observed, communicate the electricity upon the surface of the glass tube to the feather, and that when the feather had upon it the same electricity as the glass tube, the feather was repelled. Taking a stand and resting it upon the table, he remarked that he wanted something to interpose between the stand and the table which would not allow the electricity to pass from the lath placed upon it to the table. He found this something in a piece of shellac, but he might use common resin, or sealing-wax, or india rubber. He would, however, use the shellac, and he now knew that any electricity he might communicate to the lath would be prevented from going to the earth. He was forestalling matters a little, but in a few moments they would understand all he was saying. The experiment would be attended with some risk, as when he first made it that morning he wore a different coat, and he did not know whether the coat he was wearing at that time would behave as the coat he wore in the morning did. He then requested his assistant (Mr. Cotterill) to strike him with the catskin, thus electrifying him. At the same time he drew his hand over the lath, explaining that in that way he was communicating to the lath the same electricity which Mr. Cotterill was exciting upon his body. They would observe how the lath followed his hand—a movement he afterwards stopped, observing in continuation that he had communicated to the feather the electricity upon the glass, this self-same electricity proving itself repulsive. In the same way in the experiment he had just given, the electricity communicated to his hand had caused his hand to repel the lath. He would ask them to go fully into this matter with him, because it underlay the whole of electrical science. Sir Isaac Newton found his dressing gown was better for his glass than other substances. It was soon found that the electricity excited depended a good deal upon the rubber—a towel would not excite the same electricity as a catskin. Taking two sticks of sealing wax and balancing one on the cradle he rubbed the second stick and showed the attraction and afterwards the repulsion of the two substances electrified in the same way. He subsequently repeated the experiment with two pieces of gutta percha, and said he might go on with sulphur and sulphur, two paraffin candles, or paraffin and wax, or he might take ebonite and ebonite. Taking an ebonite comb he passed it through his hair, and then showed how it repelled another ebonite comb, which was balancing in the cradle. Sealing wax was a common substance, and might be taken as representative of the whole class of the so-called resinous bodies. Taking a stick of gutta percha, however, he proceeded to show the effect on it of a vitreous body. [Experiment shown.] Instead of repulsion they saw powerful attraction. He might go through the whole of these bodies, and in each case show that a resinous body repelled a resinous body and a vitreous body repelled a vitreous body. Suspending a glass tube, and exciting it by rubbing it, he took another glass tube, and having rubbed it demonstrated the repulsion of the one from the other. Having repeated the experiment with two sticks of sealing wax, he placed the glass tube in the balance, and showed the attraction between it and a resinous body—a piece of the sealing wax. He wished them to bear in mind that they were here at the fundamental law of electricity—like electricities repelled each other, unlike electricities attracted each other. The terms "vitreous" and "resinous" electricities were at the present time abandoned, and the electricity developed by glass they called positive electricity, the electricity developed by sealing wax and the resinous bodies being called negative electricity. There was, however, no reason whatever why one should be called positive and the other negative; it was simply done by agreement among scientific men, in order that they might understand each other when they talked of positive and negative. He next showed two pieces of ribbon electrified alike "standing at utter enmity to each other;" and afterwards placed a sheet of paper on a wooden board. There was not, he said, the least attraction between the two, but having passed a stick of india rubber over the paper, he showed that he required to use some force to get the paper away from the board. With two slips of paper he next illustrated the law that similar electricities caused repulsion. Several strips of paper suspended and insulated were then brought forward by the lecturer's assistant, and the former rubbed a glass tube and held it towards the strips, which at once commenced to diverge from each other—entirely owing, the lecturer observed, to the repulsion of the same kind of electricity. Calling attention next to the electroscope, he cast its shadow on the screen behind him, showing two pieces of gold leaf suspended. He then placed two balls, separated, on stands, took an arch of thick copper wire, and made the distance between the two balls sufficient to enable him to span them with the arch. Neither ball, he explained, had any power of attraction at present, but having communicated electricity to one of them by means of a glass tube, he spanned the two with the arch of copper wire, and showed how the electricity from the one was thus communicated to the other ball. This had been done by what was called a flow of electricity, and hence the notion of an electric current. To illustrate this principle still further, he attached a piece of copper wire to the arch, connecting it with the electroscope; and having touched one of the balls with the arch, he showed how a portion of the electricity thus communicated to the ball went through the wire to the electroscope, making the pieces of gold leaf diverge considerably. By means of a further experiment he caused the gold leaf again to collapse, and resume its former position. Detaching the piece of copper wire from the arch, he replaced it by a piece of dried twine, and having electrified the ball as before, showed that the twine had no power to conduct the electricity—a power, however, which he afterwards showed was possessed by ordinary undried twine. He wished to impress on their minds in a manner never to be forgotten the influence of moisture. The dried twine was rendered an insulator; the ordinary twine was a conductor. He repeated this experiment with a piece of silk, first in a dry and afterwards in a wet or damp state, and showed that in its former condition it was an insulator, while in its moist state it conducted the electricity. In the early part of his lecture he had spoken of the tendency of the human mind to inquire into the hidden causes of things; and as to these phenomena, those hidden causes were entirely beyond the range of sense. They must be seen by the scientific intellect. He wished to give them an idea of a notion long entertained by scientific men regarding electricity. There were two kinds, they said, positive and negative; and they further said that these positive and negative electricities were mixed together in all bodies. He must now come to what he called a very beautiful experiment, which occurred to him two days previously. [Experiment shown on the screen.] In front of the lamp they had a brass ball suspended and connected by wire with a cylinder of brass. Mr. Cotterill would place upon that some loose bran, and then they would see what would occur. He would excite his glass tube, which he then passed over the cylinder. This glass tube would attract the negative electricity, and the other electricity, the positive, would flow towards the brass ball, and if it reached the ball and electrified it the bran underneath ought to jump up to it. In this experiment he had not touched the cylinder with the glass tube. Supposing, however, he touched the cylinder before he brought the glass tube to bear upon it, they would see that there was no jumping of the bran. Why? Because the positive electricity, instead of going to the bran, had flowed through his body to the earth. The moment he removed his hand the liberated positive flowed towards the bran, which they saw jumping again. With this experiment the first lecture of the course was concluded.

(CONTINUED FROM PAGE 164.)

TELEGRAPHY.—We now turn to the most important application of electricity—telegraphy. By its means space is practically annihilated, and so general is this application becoming that ere long conversation telegraphically between friends breakfasting fifty miles apart may not only be possible but common. It will be seen that we agree with the legal decision that telephony is only a phase of telegraphy. By means of the latter, communication is almost instantaneous between points thousands of miles apart; by the former the crying of the baby in London can be heard by the anxious parents at Brighton. The mind almost fails to grasp the gigantic strides that have been made during the past half century in these applications of electricity. While many arts have degenerated—witness the rudeness and crudeness of our architecture, our painting, our glass staining, &c.—civilisation has progressed in the art of intercommunication. Before directing attention to the telegraphic and telephonic work in England during the past year, we may be allowed to refer generally to the position of the telegraphs in 1880-1—the latest date down to which we have complete official records. The American Government collected statistics to that date, issued with the American census report, containing a mass of interesting information, the like of which is not to be obtained elsewhere—at any rate, outside of official pigeon-holes.

GREAT BRITAIN.—On March 31, 1881, there were 4,015 post offices and 1,423 railway stations open for telegraph work, making the total number of telegraph offices within the United Kingdom 5,438, as compared with 2,488 under the telegraph companies. The date of transfer from companies to the Government was January 29, 1870, so that in the course of eleven years the number of offices had been more than doubled. On taking over the telegraphs the Post Office commenced with 5,651 miles of telegraph, with 48,999 miles of wire. At the date above mentioned these numbers had increased to 26,319 miles of line, with 121,052 miles of wire. The number of words delivered during the year ending March 31st, 1881, was 327,707,407, while the work done for the Government itself was valued at £19,479. The number of the telegraphists employed by the companies was 2,514, of whom 479 were women, the number of messengers 1,471, while the Government had respectively 5,611; of these 1,536 were women, and 4,648 messengers. These latter numbers are exclusive of those persons indirectly employed, such as those paid by postmasters out of allowances for assistants.

GERMANY.—Telegraphy has here from its beginning been a State institution. The rates for ordinary telegrams are:—(1) An initial charge of 0·20 mark for every telegram; (2) within the empire a charge of 0·05 mark per word; (3) for city, *i.e.*, local telegrams a charge of 0·02 mark per word. For urgent telegrams, to which precedence is given, a threefold charge is made. For press telegrams in the daytime the charge is 20 or 40 marks per hour, according as the Morse or the Hughes instrument is used; at night the rate is but half this amount. The value of Government messages in 1880 was about 100,000 marks.

FRANCE.—Here also the telegraph is a State institution. The tariff is 5 centimes per word, with a minimum of 50 centimes. The press messages are at the rate of 24 francs per hour for the use of a wire erected with the assistance of the paper, otherwise 50 francs per hour. In Paris the normal tariff is reduced 70 per cent. for messages despatched either by pneumatic tubes or on the newspaper's own wires. The value of the press messages in 1880 was 1,722,683 francs.

AUSTRIA.—The telegraphs are State property, but certain concessions have been granted to railways, to Vienna, to companies in local capitals, to five telegraph lines, and to cable companies. The tariff is 28 kreuzer for the first two words, and 2 kreuzer for each word after. Local—*i.e.* in same town, messages half that rate. For urgent telegrams a threefold rate is charged. Press telegrams at night pay 5 florins for 500 words, and 1 florin for each additional 100 or part thereof.

HUNGARY.—The State took over the telegraphs in 1867, when there were 650 stations, 12,271 kilometres of line, and 36,311 kilometres of wire. In 1880 the respective figures were 1,083, 15,525, and 55,137. The tariff seems similar to that of Austria, 24 kreuzer for two words, and for each word after 2 kreuzer.

RUSSIA.—The State owns the telegraphs. The tariff varies with distance. The first zone embraces Russia in Europe, as far as the meridian of Ekatérimbourg, including the Caucasus; the second, Russia in Asia, as far as the meridian of Strelinsk, including Turkestan; and the third, extending from that meridian to the extreme limits of the empire. Each of these three parts is subdivided into three zones. The first measures a distance of 200 versts, the second 1,000 versts, and the third comprises all the space beyond the second. The tax is based on a minimum of ten words; for this minimum the charge is 30 copecks in the first zone, 60 copecks in the second, and 1 rouble 20 copecks in the third. For each supplementary tax must always be increased to an even number; in the second zone, 5 copecks for each supplementary word, and in the third 10 copecks. For the

Digitized by Google

transmission of telegrams from one of the three parts of Russia to one of the others there is charged a sum made up of the charges belonging to each part. Press telegrams are subject to the ordinary charges, but special agencies, at present two in number, the International Telegraph Agency and the Agency Petersburg, Moscow, enjoy a reduction of 50 per cent. Besides these two agencies, special privileges are accorded to a daily paper at Moscow, called the *Telegraph of Moscow*. The editors of this paper have contracted for the use of a wire between St. Petersburg and Moscow every night between eleven in the evening and four in the morning. The price agreed upon was based upon the charge per word between the two capitals, which is 5 copecks.

SWITZERLAND.—The telegraphs are a State institution. In 1880 there were 6,555 kilometres of line, with 16,017 kilometres of wire. The railway lines belong to the companies, and had 328 kilometres of line, with 2,825 of wire. The total number of offices numbered 1,108; of these 932 gave a continued service, 73 were used in summer only, and 103 were railway offices. An initial charge of 30 centimes is made for internal telegrams (we have considered only internal arrangements throughout these notes), and a further charge of 2·5 centimes per word. The press receives no favour, but is charged at the ordinary rate. Official telegrams have to pay, except such as relate to the telegraph service itself.

BELGIUM.—The telegraphs belong to the State. On January 1, 1881, the complete telegraphic system comprised 823 offices accessible to the public for the transmission of telegrams, and 26,153 kilometres of wire. These lines included 22,279 kilometres of wire constructed along the railroad managed by the State, 1,883 kilometres of wire along the highways, 601 kilometres of wire along the water-courses for the use of navigation and for the announcement of the rising of the waters, 1,158 kilometres of wire attached to the poles belonging to the State by chartered railroad companies for use in their business, and 232 kilometres of underground wire. The rate of an ordinary message is 50 centimes for from one to ten words, and 10 centimes for each additional five words. Urgent telegrams are charged double, as are telegrams sent after nine o'clock at night. Belgium has no special rates for press telegrams. The *personnel* of the service comprised, on December 30th, 1880—Officers and telegraphists 1,009, workmen and messengers 1,212—a total of 2,221, besides whom are 2,162 railroad and postal agents who assist.

THE NETHERLANDS.—The system belongs partly to the Government and partly to private companies. In December, 1880, there were 396 offices, 191 conducted by the Government and 205 by individuals. A telegram of minimum length is charged 15c., for every other word 1c. is charged. No special tariff for the press.

SWEDEN.—The system is under the Government, except certain private railway lines, which are under partial control. The number of offices in Sweden at the close of 1880 was 784, of which 176 belonged to the State, 187 to the State railways, and 421 to private railways. The length of lines belonging to the State is 8,288 kilometres and 20,336 length of wire; to the State railways 516 kilometres of line and 5,406 of wire; to private railways 2,716 kilometres of line, and 3,698 of wire. In most of the telegraph districts the State and the State railway telegraphs use the same poles. The tariff is 1 kronor for 20 words or less, and 25 öre for each succeeding 5 words, with a delivery charge of 10 öre. The press is not favoured.

NORWAY.—The State owns all the telegraph lines in the country, and was the original owner of the same. The length of telegraph lines is 5,313 English miles, of which 4,634 miles belong directly to the State and 681 miles to the railways, which are owned and controlled by the State. The total length of wire is 9,726 English miles, of which 8,414 belong directly to the State and 1,312 miles to the State railways. A simple telegram of 15 words is charged 1 kronor, with a charge of 20 öre for each succeeding 3 words. The press messages are sent at a less rate for the additional words.

DENMARK.—The State owns the system, except the lines along private railroads, and one line with a special concession. At the end of 1880 the State had 128 stations, with 476·22 geographical miles of line, and 1,261·10 miles of wire, in addition to 159 stations on the Government railroads. The rate is 50 öre for 20 words, and 25 öre for each additional 10 words, or less. Press telegrams pay as ordinary, except in one case, in which a newspaper pays by the hour.

PORTUGAL.—The system belongs to the State, which had in 1880 some 930 stations and 5,329 miles of wire.

ROUMANIA.—The system belongs to the State, which had in 1880 some 102 stations, with 5,145 miles of wire. Tariff, 8 centimes per word, except for local messages, which are charged 5 centimes per word. The press rate is the same. The value of Government messages in 1880 was 97,884dols.

TURKEY.—The Government owns the system, with, in 1880, 471 offices and 45,072 kilometres of wire. The tariff varies with distance, being 9 cents for immediate district around capital and amounting to 1·98dol. for messages of 20 words to the Asiatic provinces. There is no special press rate.

POST OFFICE TELEGRAPHS.—The prevailing depression of trade has, as was to be expected, seriously affected the revenue from telegraphic traffic during the past year, the first three quarters of the financial year showing a deficiency of £5,000 against the increase of £53,000 estimated by the Chancellor of the Exchequer last April. It would appear, therefore, that the reduced tariff promised for the present year will not be inaugurated under very encouraging conditions. The reduction, however, having been definitely determined upon, extensions in anticipation of the certain augmentation of traffic have been proceeded with on a large scale. It is wisely considered that the only way to make the new tariff remunerative is to provide ample acccommodation for its transmission, so as to encourage the multiplication of cheap short messages, and this whatever may be the basis of the tariff finally adopted. A decision has not yet been come to on this critical question; but so far as the engineering preparations are concerned, there seems to be no cause for doubt as to the sufficiency of the preparations made to meet any increase of work likely to accrue for some time to come.

The additional great trunk line which had been partially advanced prior to 1884, but completed only between Glasgow and Carlisle, is now nearly finished, so that in a short time a system comprising from seven to seventeen wires will connect the metropolis with Scotland, including on its way the great commercial centres of the western counties. A similar system of equal magnitude, that is to say comprising an average of ten wires throughout, has been erected along the east coast connecting London with Newcastle and the intermediate important towns. Both these new lines have been carried along the high roads and are quite independent of the railways.

Besides these two great schemes additional circuits have been given to the following places:—Newcastle, Liverpool, Manchester, Leeds, Hull, Nottingham, Sheffield, Birmingham, Cardiff, Bristol, Portsmouth, Southampton, Margate, Ramsgate, and Dover. These new circuits are duplexed—duplex

Digitized by Google

working, indeed, being now the rule on every new wire. To provide for what may be called the increased local traffic of populous areas the circuits radiating from the chief towns have been extended and improved. Aberdeen, Glasgow, Edinburgh, Inverness, Newcastle, Liverpool, Manchester, Hull, Leeds, Chester, Shrewsbury, Birmingham, Bristol, Gloucester, Exeter, Plymouth, Southampton, Portsmouth, Belfast, Dublin, Limerick, Cork, are among the places so dealt with. The metropolis, of course, has received special attention in these respects, having had its capabilities enlarged both by additional wires and by improved apparatus. An additional cable of four wires has been laid to Jersey by the Post Office's new telegraph cable ship "Monarch," which has also laid a six-wire cable between Lowestoft and Holland in the past year.

These extensions alone represent an immense addition to the working capacity of the Postal Telegraph system; but it has been still further enlarged by improvements in the apparatus. Mr. Preece, in his recent lecture on American telegraphs, made a pointed reference to their backwardness as compared with the strides made in this country during recent years, a circumstance which has placed us at the head of all nations as regards speed of telegraphic transmission. An improved form of non-polarised relay has been introduced for quadruplex working; and the duplex system is now so far perfected that its application to the Wheatstone fast speed instrument has enabled a distance of 560 miles to be traversed at the rate of 240 words a minute with a repeater in circuit. The Wheatstone transmitter itself is the object of unremitting attention; and to enable the receiver to keep pace with it, the range of the train work has been enlarged so as to record at the rate of 400 words a minute—a speed which, incredible as it may seem, has actually been reached and perfect signalling obtained. Possessing such appliances as these, it may be said without exaggeration that all the existing wires now under Post Office control can be duplexed or quadrupled at pleasure; and that with the help of the Wheatstone fast speed instrument their capacity may be increased tenfold wherever and whenever the occasion or circumstances demand it.

In telephony the Post Office have kept pace with the public demand, which, however, is not very pressing. The existing exchanges have been improved, induction has been effectually cured, and the wires laid underground. Fresh exchanges are now on the point of being opened at Stockton-on-Tees, Derby, Hickley, and at Workington.

Cable Work.—The name of Lord Palmerston is still familiar to all, and an instance of his foresight will bear repeating. In 1848, in reply to a question, he said :—"The day will come when, if a Minister be asked in Parliament whether war has broken out in India, he will reply, 'Wait a minute; I'll just telegraph to the Governor-General and let you know.'" Then not a mile of submarine cable existed. Now we are grumbling because every important point is not connected by submarine wires. England has been and will be the great centre of activity in this work. All that her sons have undertaken has been in the direction of utility. All that other folks have done has been done in the game of speculation; but even those who play the game of speculation come to us to make, lay, and repair their cables. Our opinion of the multiplication of Atlantic cables is well known. There is not sufficient work for the cables at any remunerative tariff—we doubt if all the cables would be fully employed were there no tariff at all. Preparing for the increase of traffic is all very well; but, like the building of ships, it is possible to go too fast. Atlantic cables are too thick. In certain parts of the ocean the mending of one cable means the ending of another for the time being, for they overlay, and, as we have before pointed out, it is impossible in grappling in these parts to be sure of getting the right cable. But at present our tale is of the work of the year.

The three great English firms for cable work are the Telegraph Construction and Maintenance Company, Messrs. Siemens Brothers, and the Silvertown Company. The T.C. and M. Co., as it is known in short, has manufactured and laid the Saigon-Hué and the Hué-Tonking cables, having lengths of 270 and 515 nauts. respectively. The ships employed on this work were the company's ss. "Kangaroo" and "Calabria." These cables belong to the Eastern Extension Co. For the same company the Telegraph Construction and Maintenance Co.'s ss. "Seine" renewed portions of the Banjoewanjee, and also laid a cable for the Dutch Government across the Straits of Sunda—the previous cable having been destroyed during the earthquakes, which otherwise proved so disastrous in that region—the Darwin cable, the Singapore-Saigon cable, Penang-Rangoon cable. For the Brazilian Submarine Co. the Telegraph Construction and Maintenance Company manufactured and laid the duplicate Madeira-St. Vincent cable, 1168 nauts.; the St. Vincent-Pernambuco cable, 1,862 nauts., using the ss. "Scotia" and "Calabria" for the work. The Lizard-Bilbao cable of the Spanish Direct Company has been duplicated by the same company. The "Scotia" was employed in this work, and the length of cable laid was 473 nauts. The same vessel was also employed in repairing the Brazilian Submarine Company's old cable. A large quantity of cable has also been made for the Eastern Company, which the latter company has laid by its own ships. Thus, during the year the Eastern Telegraph Company has connected all the Grecian Islands, completing the net-work of cables in the Levant. Souakim and Perim are now within the cable connection; and gradually every place of importance in the East seems to be brought within the field of operations.

Turning now to the Atlantic, Messrs. Siemens have manufactured and laid the Mackay-Bennett Atlantic cables, consisting of two cables from Ireland to Nova Scotia, one cable from Nova Scotia to Rockport, Massachusetts, and one cable from Nova Scotia to New York City. The total length of these four cables is 6,100 nautical miles. It is interesting to know that the cable from Nova Scotia to Rockport, length 529 knots, contains two insulated conductors which are worked simultaneously by the arrangement devised by Mr. F. Jacob. The repair of both the main cables, which unfortunately broke soon after their completion in deep water, has been effected—a task which in the winter season in these high latitudes is one of considerable difficulty. The depths where the fractures had occurred, to the east of the Bank of Newfoundland, were 1,500 and 1,000 fathoms respectively, and in both repairs operations had to be carried on in depths exceeding 1,500 fathoms. The fractures appear to have been caused by the moving of the ground, as considerable lengths of the cable were found embedded in clay. The fact that three cables broke in deep water in the same neighbourhood during one and the same night also points to the same cause. These were :—The 1881 Gould cable, which broke on the 3rd October, at about 9 o'clock at night; the 1882 Gould cable, which broke on 4th October, at 4 o'clock in the morning; and the Southern Mackay-Bennett cable, which broke on 4th October, at 8 o'clock in the morning. The second Mackay-Bennett cable (the Northern cable) parted on 7th November, and the two Mackay-Bennett cables were repaired on 6th and 19th December respectively.

At the time of writing a successful cable-laying expedition is returning to Silvertown, and we must therefore defer our

Digitized by Google

remarks upon the work of the SILVERTOWN COMPANY till a few more particulars of the expedition reach us.

FELTEN AND GUILLEAUME.—During the past year Messrs. Felten and Guilleaume, of Mulheim on the Rhine (for whom Messrs. W. F. Dennis and Co., 101, Leadenhall-street, London, E.C., are sole agents), have been very busy in telegraph and telephone wires, electric cables, &c., of every description. They supplied the entire requirements of the German Postal Department in telegraph and telephone wire, besides executing large export orders for telegraph wire, &c. The patent steel telephone wire manufactured by this firm is rapidly gaining favour, and is preferable to bronze wire on account of the advantages it possesses over this latter material. Messrs. Felten and Guilleaume manufacture their patent steel telephone wire in two qualities, the first with about 60 tons per square inch breaking strain, having at the same time remarkable ductility and flexibility, and the other quality with about 85 tons per square inch breaking strain, which is rather harder. The former quality they generally recommend as being best adapted for telephonic purposes, and more easily handled. The cable department of this firm has also been very busy on orders for the German Government for both underground and submarine cables, the latter for connecting some of the islands near the northern coast of the German Empire. They also laid a cable for the Netherlands Government, connecting the islands Ierschelling, Amsland, and Schiermonnikoog, besides executing a number of orders for other foreign Governments. To the telephone cable department, Messrs. Felten and Guilleaume have been devoting their closest attention, particularly to the construction of a special aerial cable, and they have succeeded in producing a cable practically free from induction. The majority of telephone companies have given it a trial, and from repeated orders it would seem to give every satisfaction. It is manufactured with from four to fifty-two conductors.

TELEPHONY.—The telephonic system is becoming, as we always considered it must, a monopoly in each district. It is disheartening to those who desire to see the best system introduced to find that the political papers, without an atom of knowledge, have used all their influence to create a system which they will shortly denounce with all the vigour at their command. We foretold—if what was quite plain can be said to be foretold—that telephony must of necessity be of the nature of a monopoly in each district. We regard telephony as merely a development of telegraphy, and we maintain that hitherto the responsible parties in London and some other large towns have not erected their lines on any rational system known to telegraphy. It is a mere hand-to-mouth makeshift, regardless of the future, and as indifferent to public safety as to private rights. We are quite sure that the overhead system is a delusion, and come what may will have to go. Attempts are made through almost every political paper that exists to force down the throats of a disbelieving public that one of the causes why telephony does not progress so rapidly here as it ought is that the companies are stopped in their endeavours to get way leaves. If so, they have only to thank their own overbearing conduct. We have been informed more than once that our opposition to the overhead wire system is official. Once for all we may say that in no single instance has the official mind been indicated to us by word, letter, or deed. We are as independent of the Government as we are of the telephone interest. What has been said and what is now said is in the interests of shareholders. Not, indeed, shareholders who are here to-day and gone to-morrow, but those who invest their money as a permanent investment. To them our warning is given. We believe that the National Telephone Company has in some cases tried underground wires, as has the Government, with fair if not complete success. If we had the framing of a policy with regard to the telephonic interest of the country, we should suggest the compulsory purchase of private interests by the State, the extension of underground wires, the lowering of rates, and the opening of every telegraph office as a telephone office. We should like to see a fair trial made of Van Rysselburghe's system upon telegraph lines that were little worked, while the Brown-Saunders system could be largely applied to lines with little telephonic work.

BLAKEY, EMMOTT AND CO.—We understand that Messrs. Blakey, Emmott and Co., of Halifax, have during the past twelve months been kept fully employed, although with the increased number of firms in the electrical business there is increased competition, and consequently in many departments less profit. In the railway department a number of good orders have been completed, and they have again obtained the whole of the London and North Western Railway Company's contract, this time for a term of years. A good business has also been done for foreign railways, especially with Warburton and Crossley's patent bell instruments, which are gaining in favour. Amongst the new instruments introduced by this firm during the year we may mention Edmonson's calculating machine, which has already elicited very high commendation from competent authorities; Fletcher's patent watchman's tell-tale, a full account of which has already appeared in this paper, and Kapp and Crompton's current and potential indicators. Magneto bell and switch-boards, &c., for the use of the various telephone companies, have also been in good demand, and there is every indication that the next year, under the fresh arrangement made by the late lamented Mr. Fawcett, will be an exceptionally good one, and that the public will gladly welcome the concessions which are being made. During the last month this firm have been removing to new and extensive premises, and have made arrangements for the manufacture of the Pilsen lamps, and Joel's patent dynamo machines, and have also erected machinery of the latest and most improved construction for the manufacture of every description of electrical apparatus, which machinery also enables them to make all the parts of their instruments exactly alike, so as to be interchangeable, a point which appears to have been almost entirely overlooked by the generality of instrument makers, although always adopted by machine makers of any repute, and a point the utility of which it is needless to dilate upon. The new works of this firm occupy a ground space of about 2,000 square yards, and the main building is six stories high.

HARRISON, COX-WALKER, AND CO.—This firm has been busy during the year, and testifies to the increasing popularity of their "tell tales" for recording the movements of watchmen, warders, attendants in asylums, &c. The experience already gained is so satisfactory that the demand is increasing. This firm has done much in the development of telephony, and, it will be remembered, carried on litigation with the United Telephone Company with regard to the originality of the Hunnings telephone transmitter. The company has proved the stronger, and removed one more opponent to monopoly in purchasing the Hunnings patent. This step led Messrs. Harrison, Cox-Walker, and Company to drop their appeal to the House of Lords regarding the Cox-Walker receiver. The firm states that "great efforts are now being made by the subsidiary companies in the district to develop telephony by means of trunk

Digitized by Google

lines between the various towns; but until the public are able to purchase at a moderate price telephones out and out for their private use, or for use in large institutions, such as asylums, warehouses, offices, hospitals, hotels, and the like, no such development will take place as might and would under such circumstances; and the common use of the telephone in private establishments would inevitably lead to a greatly increased use of the exchange connection with others, upon which work the companies could charge and get their rentals. If the present monopolists will not do this private work, others undoubtedly will and before very long."

Messrs. TASKER, SONS, and Co., have been more especially employed in telephone exchange work and the construction of private telephone wires. One of the events of the year has been the reduction of the rates of subscription to the Telephone Exchange, with the gratifying result that more than sixty new subscribers have been added up to the time of writing, and this number is being increased almost daily. We have before referred to the Sheffield Exchange as one of the most successful private ventures in the kingdom; indeed, its position is unique. Possessing telephone apparatus in its own right, it has been able to do its business in its own way and quite independently of the large telephone companies, and we understand that it will be able to preserve its present position and to extend its operations for many years to come so far as a supply of apparatus and the means at its disposal are concerned. With 250 subscribers, the number of calls for one month have been 50,000, which shows an average of little more than ½d. per call.

ELECTRIC LIGHTING.—It is necessary to recur to this application again, and we may once more say that in mentioning specific firms our aim has been to prove to the public that work is being done. There is no other way of doing this than by stating plainly where the work has been done and who is doing it.

ELECTRICAL POWER STORAGE COMPANY.—During the past year the company have made several important developments in their storage batteries. Profiting by the experience gained in installations and the laboratory, they have modified the design of the plates to meet the many requirements of practical working. Several important advances have been made in the use of the cells for the many purposes to which they are suited. Good work has been done by means of secondary batteries in telegraphy, a large number of lines having been in constant work in London, and the cells shown to keep their charge for over three months. Owing to the great economy effected by working telegraph lines from secondary batteries, there will doubtless be a large field for their use in this way. The tramcar, driven by accumulators and Reckenzaun's motors and gearing, has been running successfully for some months at the works, and will shortly, we hear, be tried on a public line. Cells have been supplied for working electric hoists, for which they are admirably suited, as the hoist can be used at any time independently of the engine, and all transmission gearing is dispensed with. In electric lighting the use of the cells has extended considerably during the past year, and among others may be mentioned Sir W. Armstrong, at private house; Sir W. Armstrong and Co., for Italian man-of-war; Messrs. J. Edmundson and Co., Westminster, for private house lighting, &c.; Messrs. J. H. Holmes and Co., Newcastle, for private house lighting, &c.; Messrs. Siemens Brothers; the Society of Arts; C. J. Phipps, Esq., house lighting; Messrs. Waterlow and Sons, supplying arc lamps for photography; T. Nordenfelt, Esq., torpedo work; Edison Swan Company, house lighting, &c.; A. Littleton, Esq., Sydenham, private house lighting; W. Palmer, Esq., house lighting; Van der Weyde Light Company; East and West India Dock Company; J. P. Raworth, Esq., Manchester. It will be seen from the above that confidence in secondary batteries is rapidly spreading, and great progress may be expected in the coming year.

THE ELWELL-PARKER COMPANY.—During the year, owing to the increased demand for accumulators and the introduction of a new dynamo, the old firm of Elwell-Parker has been transferred to a company. The dynamo was introduced in 1883, and perhaps the latest instance of its use is that at the Stock Exchange, where three are to be found. This machine, the general form of which is now well known, has but a single layer of wire on the armature; it is practically self-regulating, as 49 lamps out of 50 may be turned off with safety to the 50th, although plain shunt-wound. There is no lead on the brushes, and the sparking is practically *nil*. Many improvements in detail have since been introduced. The accumulators (Planté and Parker-Elwell patents) have now assumed very important dimensions for large installations, some of the new cells having a capacity of 2,000 ampere hours, with a rate of charge at 200 amperes, and discharge up to 400 amperes; and this form of cell, with plates 36in. by 24in., may be economically extended in width up to at least 72in., having then a capacity of 15,000 ampere-hours, a rate of charge at 1,500 amperes and discharge up to 3,000 amperes in cases of need.

WILSON HARTNELL, LEEDS.—During the past year Mr. Hartnell has made a considerable addition to the electric lighting plant in the north of England, he having put down about 29 installations during the past twelve months. Of these six only were of arc lights. The lamps used were the Crompton-Crabb double differential brake lamps, the current used from 16 to 25 amperes. The largest of the arc installations consists of 10 lamps in series, with a current of 17 to 18 amperes. This at the present time runs for 17 hours daily. Of the incandescent installations one is with the Woodhouse and Rawson lamps, and the remainder with Swan lamps. Ten installations are in corn mills, chiefly large mills, with new roller plant, such as those of Mr. J. Ainscough, Burscough Junction, Lancashire, Messrs. Sugden and Son, Brighhouse, or Mr. J. F. Milner, Elland, Yorkshire. All the dynamos in these are Crompton-Bürgin machines. For the most part they run all night, and in a few cases day and night. Nine incandescent installations are connected with the woollen trade. At Messrs. Martin, Sons, and Co., Huddersfield, there are both arc and incandescent lights and three dynamos. These manufacturers, who are known as makers of the finest goods only, have found some purchasers willing to select and buy by the aid of the arc light. For these and the remaining installations the dynamos used have generally been Crompton-Bürgin machines, which work well. Mr. Hartnell has, however, introduced the Crompton wrought-iron machine in the *Bradford Observer* office and elsewhere. The largest of these Crompton dynamos is a 22 unit 110 volt dynamo at Mr. Charles Crabtree's, Todmorden. It runs at 480 revolutions only, and shows no visible sign of the current at the brushes. This installation illustrates the incomparable beauty of the incandescent light as compared with gas when used for manufacturing purposes. The large weaving shed (cotton), lighted by 160 equidistant pendant lights, has a fine and pleasing appearance, and gives great satisfaction to the weavers. In this installation, as in some of the others, such as Mr. Kelsey's corn mill at Gainsborough, or Messrs. Barker's factory, at Hebden Bridge, no gas has been fitted, entire reliance being placed on the electric light. In one factory, where women

Digitized by Google

were chiefly employed, the incandescent lights have been substituted for gas, on account of the langour, headache, and faintness produced by the latter. In two cases the arc light has been added, to supplement gas light. In the one (part of a woollen mill) the employer believes that its sunny beams induce such cheefulness and activity that more work is done. In the other instance, in an engineer's erecting and tool shop (Messrs. Pollitt and Wigzell's), two of the arc lights enable heavy weights to be lifted as in the daytime, and bring the whole space in distinct review at a glance. In putting up incandescent installations Mr. Hartnell has hitherto used exclusively the somewhat expensive Thompson porcelain holder, and (with occasional exceptions) a separate cut-out to each lamp with its branch wire, in addition to Hedges' cut-outs for the mains. He spares no expense and care in the details. He considers that it is now abundantly demonstrated that the electric light can be made as trustworthy as gas, as easy to manage, and for long hours much less expensive to maintain, besides being much more satisfactory to workers, who are often enthusiastic in its praise.

SIMPLEX ELECTRIC LIGHT COMPANY.—This company has fitted up a portion of Messrs. Erwen and Roby's mill at Patricroft, near Manchester. Owing to the speed the various machines were running at, the greatest difficulty was experienced to keep anything like a steady light with gas, in fact it was not uncommon for the gas jets to be blown out. The lamps employed are Müller's, manufactured by the company. Several temporary installations by means of a portable engine have been made. Amongst other works in hand are the lighting up of Messrs. J. Robertshaw and Son's Mills, near Bradford, and Messrs. T. Ormerod and Co.'s, Haslingden.

ANDERSON AND MUNRO.—We have from time to time noted the work of this firm, and will here briefly refer to one peculiarity of their year's work. It is in the large number of extensions in places where the light has been previously introduced. Thus, further work has been done at the Earnock Collieries, at the factory of Mr. J. D. Barkay, at the biscuit factory of Mr. J. Reid, Caledonian Railway Central Hotel, &c. Such orders, as we have previously remarked, form perhaps the best proof of the success of the electric light.

F. D'A. GOOLD, MANCHESTER.—Amongst the contracts for incandescent lighting which have been completed and which we have from time to time noticed may be mentioned the lighting of "Astley Bank," Darwen, the residence of C. P. Huntington, Esq.; the Park Lane Twist Company's Mills, Preston, "Larards Still" (W. T. Grimley's new establishment), Clarence and Waterloo Hotels, Manchester, &c. In arc lighting, we may mention the Wigan Coal and Iron Company's Works, Wigan, "Larards Still" (both arc and incandescent), the erecting shop of Messrs. Sharp, Stewart, and Co., engineers, Manchester. Amongst the contracts on hand not yet finished there is the new Victoria Hotel, belonging to the Corporation of Manchester, which it is hoped will be finished early in the year. Added to this work, Mr. Goold has opened a central station for the supply of electrical energy consumed, known as the "Volta-Power Generating Works," Chatham Buildings, Manchester. At present 300 incandescent lights are worked from this source.

AUSTRALASIAN ELECTRIC LIGHT COMPANY.—The extension of the electric light in Australia seems to be making good progress, and the promise for the future is perhaps better than the performance of the past. The Australian Electric Company has been in work in Victoria about two and a half years. They have devoted considerable attention to mine lighting, and have designed for this purpose special fittings and a complete system of conductors. In this direction they have met with a measure of success. We notice in a list of installations no less than twelve gold mining companies having produced a light, besides crushing works and tin companies. It has been introduced into the House of Parliament, Melbourne, and some of the Government offices; similarly at Sydney and Brisbane, besides a number of newspaper offices, hotels, and factories.

TRAIN LIGHTING BY ELECTRICITY.

Messrs. Heenan and Froude and R. E. Crompton and Co. are lighting up a suburban service of trains for the Great Eastern Railway, and it is understood that if the lighting is successful and proves itself adapted for ordinary use, the company will extend this system of lighting to other parts of their line. The plan adopted is to place a small Tower spherical engine coupled direct to a Crompton self-regulating dynamo machine on the top of the locomotive boiler.

Both engine and dynamo are fixed on a common bed-plate and coupled direct, thus doing away with belt or wheel gearing. The whole thing is exceedingly compact, an engine and dynamo suitable for feeding fifty to sixty 16 candle-power incandescent lamps measuring only 4ft. 3in. in length, 2ft. in width, and 1ft. 3in. in height. The armature of the dynamo consists of a large number of thin soft wrought iron discs insulated from each other, and supported on radial bars of phosphor bronze, which themselves are keywayed into the spindle. The core thus formed is wound with insulated copper wire in the manner of a Gramme ring, care being taken to leave sufficient open space for ventilation. The field magnets are of the softest Swedish wrought iron thoroughly annealed, and the winding is put on by means of detachable formers, thus making the changing a coil, should one ever get damaged, a very easy matter. Up to the present, however, no mishap of any kind has occurred to any of the dynamos which have been at work for the last two months. The dynamos are wound on what is known as the compound system, and are therefore self-regulating—that is to say, if driven at a constant speed they will light one or fifty or any intermediate number of lamps, with the same brilliancy in each lamp, requiring no regulation whatever on the part of the driver. To keep the dynamos running at a constant speed a centrifugal governor is fitted to the engine, and all the locomotive driver has to do is to turn on the steam into the little engine when the light is required, and then leave the apparatus to itself. It is not easy to give a description of the Tower engine without the aid of diagrams, suffice it to say that all the moving parts of this remarkable engine are contained within a sphere of 5in. internal diameter, only the shaft protruding. The pistons are semi-circular discs, having a rotary and oscillating motion combined, and the admission and exhaust of steam is effected without the use of a separate slide valve.

The engine and dynamos are placed on top of the locomotive, and steam is taken from the locomotive boiler. A pair of cables well insulated and provided with clip couplings in front and rear of each coach extends throughout the train, and smaller wires are attached to this main for feeding the single lamps.

The lamps are of 16 candle-power each, placed in the roof of the carriages in the same openings which used to serve for the reception of the old-fashioned oil lamps, and the connection with the wires is made automatically by simply dropping the globe containing the incandescent lamp into place. An improvement is now being introduced, whereby the lamps will be fitted from the inside of the carriages instead of from the outside, thus doing away with the necessity of men getting on to the roof.

The system has been in successful operation for the last two months, and it is believed will prove a great success.

PERSONAL.—Messrs. H. E. Harrison and C. J. Wilson, of the Hammond Company Electrical Engineering College, will in future carry on their consulting practices at the Hammond Company's College.

CORRESPONDENCE.

TELEPHONING SERMONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice some remarks in your issue of this date respecting the transmission of sermons by telephone, and giving June, 1882, as being the date on which they were first so sent.

I may say that I fitted up my patent microphone transmitters in the chapel here, of which the late Dr. Mellor was minister, as long ago as January, 1879, since which period they have been in constant Sunday use. On Easter Sunday in the same year the sermon was transmitted along the wires of the Lancashire and Yorkshire Railway to Manchester, a distance of thirty-two miles. The Manchester papers of the morning following contained an account of the experiments. With one of Edison's chalk receivers, I am able by special arrangements to reproduce the sermon loud enough to be heard from one end of my billiard room to the other.

Perhaps you would kindly insert this in your next publication.—Yours, &c,

LOUIS J. CROSSLEY, M.S.T.E.

Moorside, near Halifax, Jan. 3, 1885.

HEATING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice an interesting letter from Mr. Sellon in your issue of to-day; and to warn many who may follow in the steps therein indicated without due consideration I am tempted to address this letter to you.

Electricity for heating purposes cannot for one moment be seriously thought of at present, if a steam or gas engine is used to produce the current in the first instance.

In the first case, one-tenth of the heat of the coal only is recovered; then, say, 25 per cent. of power is lost in the dynamo; and finally, 25 per cent. or more lost on conversion of the current into heat. Thus we get $0{\cdot}1 \times 0{\cdot}75 \times 0{\cdot}75$ of the heat of the coal $= 0{\cdot}05625$, or say, at best, $\frac{1}{20}$ only. Even if coal were burnt in an open fire-place, not more than half the heat is lost. With a gas engine matters are not much better. In short, taking the expense of machinery, &c., into consideration, it is fair to assume that heating by electricity is at least 50 or 60 times more expensive than burning coal direct in the most approved stoves, and 25 to 30 times dearer than coal burnt in an open fire.—Yours, &c., DAVID SALOMONS.

Broomhill, Tunbridge Wells, Jan. 3, 1885.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The communications of Professor Dolbear and Mr. Sprague in your last two numbers mark a satisfactory advance in the attitude of skilled observers towards the new and urgent question of personal safety and electric currents. Each of the correspondents, however, tends to accentuate, and probably to overstate, his partial view of the whole problem.

It may be worth while to reprint part of a letter of mine which appeared in the *Globe* of August 7th last, and to which I still substantially adhere:—

"A new industry, and a fresh industrial danger, has arisen among us from the use of enormous electrical current. Although several startling accidents have already occurred, no means have been adopted, so far, for tracing them to their real cause, and thus preventing their recurrence. The lightning explanation is obviously not tenable as regards some. I have already stated that actual catalysis, or decomposition of the body, is not impossible, and that probably thrombosis, or coagulation of blood in the living vessels, occurs in other cases. I found it, however, as you state, very difficult to obtain trustworthy details. Mr. Latimer Clark, the eminent telegraph engineer, has promised to help me. But it is important that public attention should be drawn to the question, as with longer use, wear of machinery, failure of insulation, and natural negligence, due to greater familiarity, it is not unlikely that such accidents will increase rather than diminish in frequency."

Both the writers above named ignore the immense error hitherto made in the estimation of human resistance. Mr. Sprague, indeed, reasserts erroneous statements with a cautious qualification. A patient tested yesterday in hospital gave, from foot to foot, with alternate currents on Professor Kohlrausch's meter bridge, a resistance of 620 ohms, instead of 5,000 ohms, per Sprague's minimum. Salt water was used to overcome the transitory deception and dangerous skin-insulation. A workman, with his hands freshly removed from dilute sulphuric acid, would give a smaller figure.

From experiments made last week in Professor Stocker's laboratory at Cooper's Hill, in conjunction with Mr. W. G. Gregory, "it appeared," to use Mr. Gregory's own words, "that with the coil developing a mean E.M.F. of 9·02 volts, on touching the terminal with my fingers I experienced a decidedly uncomfortable tingling. Now, although the mean E.M.F. may be only 9·02 volts, yet I believe that the maximum E.M.F. at some instants must be very much greater; and it is this maximum which we want to get at."

This I believe to be true, but not the whole truth. Professor Dolbear states correctly that time and work both need to be considered.

I should add that the cause of danger is not always or necessarily the same; indeed, there is good evidence to this effect.

Mr. Sprague's statement that "the real danger is due to a physiological effect of the static actions which accompany the setting up of the difference of electric potential" *may* perhaps be true in the case of shock; but, before admitting it, even in a limited degree, it is desirable to know what is the "physiological effect," and what are the "static actions" thus mysteriously indicated.—Yours, &c., WILLIAM H. STONE.

St. Thomas's Hospital, December 3rd.

BATTERY FOR LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last number Mr. Andrews asks for "a battery (not Grove or Bunsen)" to run an incandescent lamp. I suppose that Mr. Andrews excludes the Bunsen on account of the noxious fumes that it gives off.

I would propose a modification of this battery, due to Mr. d'Arsonval. It has a high E.M.F. (two volts), a low resistance, is constant on a short circuit, and has the advantage of giving off no noxious fumes, although it smells a little of chlorine.

In an ordinary Bunsen cell put in the porous jar—nitric acid, one part (by volume); muriatic acid, one part; water, with one-twentieth of sulphuric acid, two parts. Outside the porous jar with the amalgamated zinc—water, 20 parts; sulphuric acid, one part; muriatic acid, one part. A cell 8in. high has a resistance of one-tenth of an ohm, and will furnish *without weakening* 28 ampere hours.—Yours, &c.,

110 Bis., Br. Malesherbes, Paris, Jan. 4, 1885. H. O. BAILEY.

PROFESSOR FORBES'S PAPER ON THE DIAMETER OF CONDUCTORS—A NUMERICAL CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It will be remembered that Professor Forbes's important paper on the diameter of conductors to prevent overheating—a paper whose great value has been recognised by the S.T.E. and E.—contained some rather alarming conclusions respecting the mass of metal required to convey very large currents by the underground conductors. The importance of the question must be my apology for venturing to call attention to a numerical error which occurs in the professor's approximate solution of this problem. He arrives at the formula

Digitized by Google

$C^2 = \frac{b^2}{80\,R}$, where b is the width (in centimetres) of a conductor assumed to be 1 c thick, and R is the specific resistance of the metal at an assumed temperature of 65° C. For copper $R = 2 - 0{\cdot}31 + 10^{-6}$ ohm.

We have, therefore,

$$C = \frac{b \times 10^3}{\sqrt{162{\cdot}48}}.$$

C is then put = 25 b, whereas the true value is C = 78·46 b.

It will be found that the error arose from the misplacement of a decimal point before extracting the root.

The specimen table which immediately follows (in the original paper) is calculated from this erroneous value, and shows that a copper conductor 1c. thick to convey 70,000 amperes would have to be 28 metres in width. The corrected value is 8·9 metres, which still leaves a substantial mass of metal, weighing about 1½ ton, per lineal foot.—Yours, &c.,

Tiverton, Devon. W. H. SNELL.

ELECTRO-MAGNETS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am but a poor little working unit in this wonderful world of ours, yet I have my own ideas and wants; and amongst the latter are some "wants to know," and, kind Mr. Editor, I on behalf of several fellows in our office am to ask you to help us to get to know. I was talking the other day to an old office chum of mine—Mr. Unit Field—about our income-tax assessment, and he told me that he had but a very hazy notion as to what he was really worth, and he said, "I cannot really tell you until I have gone into the books of our concern; and it is very funny that Mr. Magnetic Moment is in pretty much the same difficulty. Of course your value here is fixed very clearly, but we less practical folk have very vague ideas about our true position." Well, Mr. Editor, from one thing to another our talk led (we are an electrical firm) to some remarks about electro-magnets, and I found that Mr. Unit Field was interested in designing some. He asked me a question or two that I really thought I knew all about, but I did not. He had entered into the design of an electro-magnet that was to have a certain strength—I forget now whether it was intended to lift a weight, or to induce a current in the armature of a dynamo machine; but, anyhow, he wanted to know what size the iron should be, and what number of turns of wire he should put on, and what current he should use. Now, it is so very funny that these fellows, Unit Field and his friend Magnetic Moment, although they have to do with these things every day, don't know how to work this out; and I, too, who have something to do with these things, can't help them. He suggested that the new fellow, Gauss, might help us; so we turned into his room, where we found him reading the paper—for being new his duties are little known to the others yet. But we could not get much from him, so we all went to the Patent Office Library together to look the matter up. When we got there we thought we had found all we wanted to know, for there were scores of papers relating to the subject, filled with those beautiful "double fiddle f's" that always give so much information; but after a long afternoon there we came away, feeling very much as if we had been eating pasties, puffs with no jam to speak of inside. Now, Mr. Editor, won't you or some of your good readers help us?—Yours, &c.,

VOLT AMPERE.

DOMESTIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A short time ago, through your columns, I obtained a very fair idea of the cost of "private electric installations for lighting," which were, on the whole, very satisfactory—in fact, a great advance on district or large area installations, as regards private individuals.

Since that time, in your impression of December 27, 1884, I have seen your article on the "Trouvé lamps."

After considering all points, I think an advance has been made in "domestic lighting," or can be developed more easily than could have been expected.

Companies have failed, and, from their constitution (in my opinion), must continue to do so; but electric lighting, both in large and small areas, must, and, despite of every obstacle, will advance. I therefore hail with delight the "development" of the Trouvé system as regards small domestic lighting.

As regards "the Trouvé system," therefore, would you kindly, through your columns or by correspondents, inform me as to 1st, the prices of the three portable lamps (Trouvé) on page 129, Vol. XIV., No. 7; 2nd, the sizes of each three descriptions; 3rd, the time, *i.e.*, number of hours, for which they respectively last.—Yours, &c., G. E. R. HARRIOTT.

12, Alexandra-place, St. Andrews, Fife, N.B.
January 7, 1885.

DR. ARON'S COULOMB-METER.

In a paper read before the German Society of Electricians, Dr. Aron described his new electricity counter, or Coulomb-meter, which, in point of simplicity of construction and accuracy in its indications, would seem to be the best of any integrating instruments yet devised. A complete theory of this apparatus will be found in the December number of the *Elektrotechnische Zeitschrift*, but we propose to give here a short abstract of it.

The meter consists of an ordinary pendulum clock, the pendulum of which carries a permanent steel magnet instead of the usual bulb, which magnet swings over a wide coil traversed by the current to be integrated. In so far the arrangement is similar to Messrs. Ayrton and Perry's ergmeter. There is, however, this difference, that by the employment of a magnet instead of a shunt coil, current is integrated instead of energy, and that the main coil is not behind the pendulum but below it, an arrangement for which Dr. Aron claims that the dynamical pull of the coil is exerted in the same direction as the force of gravity. The number of oscillations performed by the pendulum in t seconds if no current passes is

$$n = \frac{t}{\pi}\sqrt{\frac{PL}{K}}$$

where P is the weight, L the length, and K the moment of inertia. Let M be the magnetic moment of the magnet, C the current, and α a coefficient, then we obtain the number of oscillations performed by the pendulum in the same time if a current is passing

$$N = \frac{t}{\pi}\sqrt{\frac{PL + \alpha M C}{K}}$$

or

$$N = n\sqrt{1 + \frac{C}{\beta}},$$

if for brevity we write

$$\beta = \frac{PL}{\alpha M}.$$

The apparatus is so arranged that the magnetic attraction is small as compared to the weight, and therefore $\beta > C$ in all cases. By developing into a series it is permissible to neglect higher power than the second of $\frac{C}{\beta}$, and we obtain

$$N = n\left(1 + \frac{C}{2\beta} - \frac{C^2}{8\beta^2}\right)$$

The coulombs passed in t seconds equal t C, and since n and t are in a fixed ratio to each other, the quantity of electricity is also proportional to n C. By transforming the above equation for N, and introducing the symbol Q for coulombs, we obtain

$$2\beta(N - n) = Q\left(1 - \frac{C}{4\beta}\right).$$

From this equation it will be seen that the difference between the number of oscillations performed by the pendulum with and without a current passing is not strictly proportional

Digitized by Google

to the quantity of electricity, but is too small for the larger currents, the error being $\frac{100\ C}{4\ \beta}$ per cent. To minimise the error it would be necessary to make β very large as compared to C—that is, to employ a very heavy pendulum and a very small magnet; but then the rate of acceleration of the clock would be too small as compared to variations due to temperature and other disturbing causes, and the instrument would become inaccurate on account of these. The clock employed by Dr. Aron had a pendulum beating 80 times a minute, and the acceleration varied with different currents, but never exceeded 240 beats per hour. The maximum rate of advance was therefore three minutes per hour. The errors found in a long series of experiments varied between 2½ and 8 per cent., but instead of being negative, as should be expected from the formula, they were found to be positive, the reason being that the stronger currents temporarily increased the moment of the magnet, and thus accelerated the clock beyond the rate which would have to be expected with an absolutely unchangeable magnet. The remedy lay near and was at once applied by substituting a magnet just hardened sufficiently so that its temporary magnetic moment should suffice to eliminate the error. Dr. Aron seems to have succeeded well with this arrangement, as may be seen from the following table, giving the results of experiments extending over two days:—

	Ampere hours.	
Current in amperes.	By coulomb-meter.	By calculation.
23·2	11·6	11·6
13·8	11·1	11·0
9·6	−0·1	0·0
4·9	9·8	9·8
2·4	7·2	7·3
0·96	3·8	3·8

The author further describes his energy meter, designed on similar lines. The bulb of the pendulum is replaced by a coil of fine wire connected as a shunt to the mains, the convolutions of this coil being vertical. Two main coils, one on each side, are so placed that the shunt coil partly enters into them at each beat. A small piece of soft iron is added to the pendulum, in order to introduce the correction as above explained. The results obtained with this apparatus are also extremely satisfactory. We need not reproduce here a rather long table of readings, but must be content to note that in a trial extending over three days, the total energy indicated by Dr. Aron's meter amounted to 28·70 megawatts, whilst the energy computed from current and electromotive force was found to be 28·63 megawatts. During the tests the current varied between 2·35 and 22·2 amperes and the E.M.F. between 50 and 100 volts.

TRANSFORMATION OF ENERGY INTO CURRENT.

J. Van Moorsel contributes the following observations to *L'Ingenieur-Conseil*:—According to the data of thermo-chemistry, the quantity of heat disengaged by the combination of a zinc equivalent (or rather half-equivalent, since zinc is diatomic) with its corresponding weight of oxygen, equals 42·63 small *calories* (32·5 grammes × 1·3 *calorie* = 42·63); and that disengaged by the sulphatation, 10·24 *calories*, making together 52·87 *calories*, the quantity of heat disengaged by the combustion of 1 gramme (15½ troy grains) of zinc being 1·3 *calorie*. From this quantity must be deducted 34·4 *calories* for the heat absorbed by the decomposition of an equivalent of water. There remain 18·41 *calories*, which correspond with the E.M.F. of a Smée couple (zinc-platinum with diluted sulphuric acid). Now, if I perform the inverse operation to that which takes place in the Smée couple, if I electrolyse a sulphate of zinc solution, the metal will be deposited on the negative electrode, and the acid will go to the positive pole. Instead of producing the current, it is the electricity which will be consumed. This current will have to overcome—1. the resistance inherent in the electrode; 2. the resistance to electrolysis without chemical decomposition (inverse electromotive force); and 3. that which causes the decomposition. These three resistances consume a certain quantity of energy, the first of which is pure loss, at any rate as regards stored-up current. Thus, for the decomposition or water, an E.M.F. of 1·46 volt would be required for the resistance of an ohm. The electrolysis of sulphate of zinc furnishes the elements of a Smée couple; it is therefore evident that the energy restored by the current of this element will only be a small portion of that expended, or 35 per cent. The electrolytic action only stores up 45 per cent.; it must therefore absorb 45 per cent. of the 35, or 15¾ per cent. of the initial mechanical energy. This doubtless supplies one of the reasons why attempts at storing current by means of gas batteries have not been successful. Another cause must be sought in the heat produced by the compression of the gases, when working under pressure, as must be the case so as to render the apparatus less cumbrous, if practical applications be hoped for, such as the propulsion and steering of balloons, for instance.

THE DRAWBAUGH TELEPHONE CASE.

AMERICAN BELL TELEPHONE COMPANY AGAINST THE PEOPLE'S TELEPHONE COMPANY ET AL.

The following is the decision of Judge Wallace in this case. We give the decision *verbatim* for the historic value it will necessarily have:—

The suit is brought to enjoin the defendants from using, and furnishing to others for use, the several inventions described in two patents granted to Alexander Graham Bell, of Salem, Massachusetts, being No. 174,465, bearing date March 7, 1876, for "Improvements in Telegraphy," and No. 186,787, bearing date January 30, 1877, for "Improvements in Electric Telephony." The issues made by the pleadings are practically resolved into the single question, to which the proofs and arguments of counsel are mainly addressed, whether the patentee Bell, or Daniel Drawbaugh, of Milltown, in Cumberland County, Pennsylvania, was the first inventor of the electric speaking telephone.

Concededly Bell was an original inventor of the telephone, the principle of which, with the essential means for its application, are described in his first patent, and of the improved apparatus described in his second patent. The fifth claim of the first patent is for "the method and apparatus for transmitting vocal or other sounds telegraphically by causing electrical undulations similar in form to the vibrations of the air accompanying the said vocal or other sounds substantially as set forth." This patent has been judicially construed in two cases in the Massachusetts Circuit; and in both cases it was substantially held that Bell was the discoverer of the new art of transmitting speech by electricity, and the claim should receive the broadest interpretation to secure to the inventor, not the abstract right of sending sounds by telegraph without regard to means, but all means and processes described which are essential to the application of the principle. American Bell Telephone Company *v.* Spencer, 8 Fed. Rep., 509. Same *v.* Dolbear, 5 Fed. Rep., 448.

In view of the conclusion reached upon the merits of the issue it is not material whether Bell's inceptive invention did or did not antedate the time of filing his application for the first patent. That application was filed February 14, 1876. It describes apparatus which was an articulating telephone whether Bell knew it or not. Mr. Cross, an expert, caused apparatus to be made in conformity to the descriptions and to drawings as shown in Fig. 7 of the patent, which proved itself to be an operative, practical telephone. Probably the date of his inceptive invention might be carried back to July, 1875, but irrespective of the time of the invention the justice of his claim to be an original inventor of the telephone must remain unchallenged. It was through him also that the telephone was made known to the scientific public, and thence introduced into commercial use.

The defendants contend that long before Bell had perfected his invention, and long before its mental conception by him, Drawbaugh had not only made the same invention, but had perfected improvements in organisation and detail which Bell has never reached, and which were only reached years afterwards by the work of many other inventors in the same field of improvement. Their theory of the facts is stated with substantial accuracy in the answer to the bill of complaint. The answer, among other things, avers that Drawbaugh was and is the original and first inventor and discoverer of the art of communicating articulate speech between distant places by voltaic and magneto electricity, and of the construction and operation of machines and instruments for carrying such art into practice; that the said electric speaking telephones so constructed and successfully and practically used by him contained all the material and substantial parts and inventions patented in the two patents granted to Bell, and also contained other important and valuable inventions in electric and magneto telegraphy; that some of the original machines and instruments invented, made, used and exhibited to many others long prior to the alleged inventions of Bell are still in existence and capable of successful practical operation and use, and are identified by a large number of persons who personally tested and used, and know of their practical operation and use in the years 1870, 1871, 1872, 1873, and 1874, and both subsequently and prior thereto; that said Drawbaugh for more than ten years prior to 1880 was miserably poor, in debt, with a large

Digitized by Google

and helpless family dependent upon his daily labour for support, and was from such cause alone utterly unable to patent his said invention or caveat it, or manufacture and introduce it upon the market; and that said Drawburgh never abandoned his invention nor acknowledged the claims of any other person thereto, but always persisted in his claim to it, and intended to patent it as soon as he could obtain the necessary pecuniary means therefor.

Drawbaugh, in his testimony, adopts the statements of the answer as true. He also testifies that he commenced his experiments with the electric telephone as early as 1866; that prior to or as early as in 1867 he had made apparatus (in which he employed a teacup as the body of the instrument), through which speech could be transmitted feebly and incoherently, and that as early as the birth of his son Charles he had so progressed that his wife, who was then confined to her bed, could by listening with one of his instruments hear the words spoken by him in the other instrument in a distant part of the house. His son Charles was born in 1870, and if Drawbaugh's narrative is true he had succeeded at that time in transmitting speech distinctly through his instruments, although whispered words would not be accurately heard. He describes instruments which he says were made by him from time to time as experiments led him from one improvement to another. He testifies that he thinks he made his first telephone apparatus prior to November, 1866, and is positive he had it before he moved his shop to the "Clover Mill" in 1867. As he describes it, the body of the transmitter was a porcelain teacup, the diaphragm was of membrane, the electrodes interposed in the circuit were copper, with the upper one connected to the diaphragm by a wire so as to vary the pressure of a conductor of fine earth or pulverised charcoal through the action of the sound waves, and the receiver was a tin can without a top or bottom, having a membrane diaphragm stretched over one end connected by a tense cord to an armature supported on a spring, and arranged close to the poles of an electro-magnet in the electric circuit. He testifies that subsequently he constructed apparatus upon the same general principle with some change of detail, and he produces exhibits "F" and "B," the former a transmitter and the latter a receiver, as the remnants of the original instruments. Exhibit "F" is a glass tumbler; and he states that at first he used a membrane diaphragm over it, and then one of thin metal, and that for the conductor he used carbons, or carbons mixed with bronze powder, and used various tops or mouth pieces to speak into it. The exhibit "B," he says, was the receiver, and in this he had discarded the string and the spring of his earlier receiver. He says that experiment led him to improve the transmitter "F" by substituting a metal diaphragm in place of membrane, and he produces a sketch. A reproduction of this instrument has been made by him for use in the proofs, "which is designated as Exhibit F reproduced." In this the mouthpiece is modified in size and in distance from the diaphragm. He made, according to his testimony, a new receiver of more perfect construction, and produces the remnant of the original, which is designated "Exhibit C." As he describes the instrument it was a decided advance upon the former receiver. In using this he says he tested it also as a transmitter with some success, and then improved it by placing a permanent magnet against the heel of the electro-magnet, and thus made a magnetic telephone. A reproduction of such an instrument as he describes is made and referred to in the proofs as "Exhibit reproduced C." After Exhibit "C" he produces "I," "A," "E," and "D," as likewise original instruments made respectively in the chronological order of their production as exhibits. He states that "I" was used by him as a companion instrument to "C." Exhibit "A" discloses a modification of form and a higher degree of mechanical adaptation. The last two, "D" and "E," are concededly perfect, practical instruments, and according to the testimony of Mr. Benjamin, an expert witness for the defendants, would compete successfully for public patronage with any magneto telephone which had been introduced into use in 1882. It is asserted of these instruments by counsel that no higher development of the telephone has been reached at the present time than is indicated by Exhibits "E" and "D." Drawbaugh does not attempt to locate the time at which he made any of these instruments, or even the year. He testifies, however, that he made all of them prior to the time the "Axle Company" commenced business, which was in December, 1874, except "E" and "D," which were made about that time.

The theory of the defendants is, that Exhibits "F" and "B" were used by Drawbaugh in 1867, 1868, and 1869, Exhibit "C" in 1869 and 1870, Exhibit "I" in 1870 and 1871, Exhibit "A" in 1873 and 1874; and that Exhibits "E" and "D" were made in January or February, 1875, although cruder instruments essentially similar were made somewhat earlier. It is in proof that 33 patents were granted for improvements in telephones in 1878, 64 in 1879, more than 100 in 1880, and 94 in the first six months of 1881. According to the theory of the defendants, therefore, as early as February, 1875, Drawbaugh had not only distanced Bell in the race of invention, but also Gray and Edison, and had accomplished practically all that has since been done by a host of other inventors.

The case for the defendants must stand or fall by this theory. The proofs leave no room for fair doubt that defendants' contention is substantially true, or that the defence has no foundation in fact. It is true that Drawbaugh had long been treading his solitary path of investigation and experiment in poverty and obscurity, but had perfected his work when the inventions of other explorers were in embryo, or his story is an ingenious fabrication. And, as will hereafter appear, if the defence is a fabrication many disinterested witnesses have contributed innocently to give it colour and strength, but Drawbaugh has deliberately falsified the facts.

The complainant starts with the benefit of the presumption of law that Bell, the patentee, was the inventor of that for which the letters patent were granted to him. Whoever alleges the contrary must assume the burden of the proof. Evidence of doubtful probative force will not overthrow the presumption of novelty and originality arising from the grant of letters patent for an invention.

It has been frequently held that the defence of want of novelty or originality must be made out by proof so clear and satisfactory as to remove all reasonable doubt. Washburn *v.* Gould, 3 Story, 227; Smith *v.* Fay, 6 Fish, 446; Hawes *v.* Antisel, 2 B. and A., 10; Patterson *v.* Duffy, 20 Fed. Rep., 641; Wood *v.* Cleveland Rolling Mill Company, 4 Fish, 560; Parham *v.* American Button Hole Company, 4 Fish, 482; In U.S. Stamping Company *v.* Jarrett (18 Blatch, 469), Blatchford, J., said the defendant had not fulfilled "the necessary obligation of showing beyond any reasonable doubt" that Weber (the alleged prior inventor) was prior to Heath (the patentee). In Coffin *v.* Ogden, 18 Wall, 129, Mr. Justice Swayne, delivering the opinion of the Court, stated the rule applicable to the defendant as follows:—"The burden of proof rests upon him, and every responsible doubt should be resolved against him."

To overthrow this presumption and disprove that Bell was the first inventor the defendants introduce the testimony of nearly 200 witnesses tending to prove the priority of invention by Drawbaugh. As the complainant concedes that Exhibits "E" and "D" are highly organised practical telephone instruments, and fully capable of perfect articulation, the patents are invalidated if these instruments were in existence at the date of Bell's invention; and as will hereafter appear they were in existence as early as in 1875, or it is incredible that they existed at all until long after Bell's first patent had been granted, and his invention had attracted general public attention at the Centennial Exposition and elsewhere.

In the argument for the defendants great stress is placed upon the evidence of a gradual and natural development of Drawbaugh's invention shown by the original instruments produced, beginning with Exhibit "B" and ending with the perfect magnetos "E" and "D." It is strenuously urged that these exhibits fortify his testimony describing the instruments no longer extant, and mark the origin and culmination, beginning with the cup machine and Exhibit "F" of two separate lines of invention—one leading to the battery telephone, in which the undulatory vibrations are controlled by variations on the resistance of the circuit, and the other to the magneto-telephone in which the vibrations are created in the electromotive force of the current.

The general theory of the defence is substantiated by three classes of witnesses; those who heard of the existence of Drawbaugh's "talking machines" at various times; those who talked through the machines on various occasions or heard others talk through them, and those who attempt to identify one or more of the exhibits as the instruments they saw or used. Only an outline of their testimony will be given.

More than fifty witnesses testify to having heard of the talking machines prior to February 14, 1879.

Of these witnesses three think they heard of them in 1869; three in 1870; two in 1871; five in 1872; three in 1873; three prior to 1873; eight in 1874; two in 1875; from 1866 to 1876, one; from 1868 to 1871, one; from 1868 to 1873, one; from 1869 to 1870, one; from 1869 to 1876, one; from 1871 to 1872, two; from 1872 to 1873, one; from 1873 to 1874, one; from 1873 to 1875, three; from 1874 to 1875, one; from 1874 to 1876, one; from 1872 to 1876, one; prior to 1869, one; prior to 1872, two; prior to 1875, one.

Sixty witnesses do not attempt to identify any particular instrument, but testify that they saw a talking machine or talked through it or heard it talked through at Drawbaugh's shop on occasions subsequent to 1867, and most of them fix the occasion as prior to 1876. The substance of the testimony of some of them will be given.

Wilson G. Fox testified that he saw the talking machine at Mr. Drawbaugh's shop about the year 1867 or 1868, when the old Faucet Company was in operation there. Prior to March, 1871, the witness was employed in the carding room of the Harrisburg cotton mill, and Drawbaugh came there to get material to wrap his wire to use for the talking machine. Henry Bonholtzer testified that he was at Drawbaugh's shop in 1869, and saw talking machines there. Margaret Brenneman testified that she saw the talking machines at Drawbaugh's shop in 1869. Abraham May testified that he did work on Daniel Hart's house at Milltown in August and September, 1870, of which he produces his account books; that he never did any work for Daniel Hart after that; that while doing that work he was at Drawbaugh's shop to get a boring machine mended which he was using in the work, and Drawbaugh showed him his talking machines, and talked through them from one floor of the shop to another. The witness understood and heard through the machines the words that Mr. Drawbaugh spoke into it. His testimony is corroborated by Jacob H. Kilmore, William H. Martin, and John A. Smith. Cyrus Orris testified that he saw Drawbaugh's talking machines at different times from about the 1st of April, 1871, down to 1880, and took his son-in-law, Jacob E. Smith, to Drawbaugh's shop to see the machines about April 1st, 1871. Benjamin K. Goodyear testified that in 1871 he seized the personal property of George W. Kissinger, of Milltown, upon an execution issued November 13, 1871; that on December 4, 1871, the attached property was appraised, and on that day witness went to the workshop of Daniel Drawbaugh to find J. B. Drawbaugh to summon him as an appraiser, and had to wait for him there a short time; that while waiting there Daniel Drawbaugh showed him his talking machines, and talked through them to him, and witness heard him speak and understood distinctly the words that he spoke through the instrument; and that he was never in Drawbaugh's shop afterwards so far as he can recollect. George Natcher testifies that he lived at Milltown in 1871 and 1872, and never has been in the town since August 9, 1872; that while living there he was at Drawbaugh's shop and saw and talked through the talking machine on different floors, and listened at the same machine and understood what was said through it. Mrs. B. B. Spangler, a sister of George Natcher, testifies that she moved away from Milltown in 1872,

Digitized by Google

and never has been there since; that she talked into Drawbaugh's talking machines while she lived there; and that she was so small that Harman Drawbaugh had to lift her up to enable her to talk into the machine. Mrs. Mary Free testifies that she was with her sister, Mrs. Lydia Drawbaugh, at Drawbaugh's shop in September, 1872, when he talked through the machines to them, and she remembers hearing through the machines, "Good afternoon, ladies!" Drawbaugh told them that the machines operated by electricity. Mrs. Lydia Drawbaugh testifies that she saw the talking machines in September, 1872, her sister, Mrs. George Free, being present. David M. Ditlow testifies that he saw Drawbaugh's talking machine about 1872, when Drawbaugh talked through it, and witness heard and understood through the machine what he said. David K. Ernest testifies that he was at Drawbaugh's shop with John B. Bloser about the middle of June, 1872, and talked with Drawbaugh about the talking machines, and thinks he saw them at that time. This testimony is corroborated by John Bloser. N. W. Kahney testifies that he saw the talking machines about 1872. William H. Martin testifies that he was at Milltown with John Keefauver to get George Hosler to make him a pair of boots. Hosler lived at Milltown only from March, 1872, to March, 1873. At that time witness and Mr. Keefauver went down to Drawbaugh's shop and talked through the talking machine from the basement to the attic, and heard and understood what was said through the machines. They talked and listened at the same instrument. John F. Keefauver corrobates Mr. Martin, and also states that he talked through Drawbaugh's talking machine with Jacob M. Sadler in April, 1873, prior to the death of George B. Hick, and that about two or three years before he saw the talking machines he had heard a good deal about them, and first heard of them at a place seven miles west of Carlisle. Wm. W. Snyder testifies that he was at Drawbaugh's shop on Wednesday, Feb. 5, 1873, and saw the talking machines. He verifies the date by an entry in his diary. Jacob Barber testifies that he was a candidate for the office of County Commissioner of Cumberland County in the summer of 1873, and in connection with his canvass went to Drawbaugh's shortly after the death of George B. Hick. While at Drawbaugh's shop he saw the talking machine and was never in the shop after July or August, 1873. Ezekiel Worley testifies that about the year 1873 he saw the talking machines at Drawbaugh's shop. His statement is corroborated by John K. Taylor. Abraham Ditlow testifies that he knew of Drawbaugh's talking machine in 1874, and saw it and talked through it at that time. He had forgotten the fact, but was reminded of it by Mr. Alexander Milner, of Porter County, Indiana, whom witness told about it in May or June, 1876, in Indiana. William Eppley testifies that he visited Drawbaugh's shop for the last time in May or June, 1875; that he was there several times during the two years preceding that period, and had seen talking machines. Jonathan Fry testifies that he was at Drawbaugh's shop with Mr. Hamme and Mr. Frederick in the winter of 1875-6, and saw the talking machines there. Jacob Evans testifies that he was at Drawbaugh's shop with his wife, his brother Andrew, and his sisters Margaret and Sarah about December 1, 1875, and saw and talked through the talking machines. Henry L. Hamme testifies that he was at Drawbaugh's shop either in the last of January or the beginning of February, 1876, in company with George Frederick and Jonathan Fry, and saw and talked through the talking machine at that time; that he heard and understood very plainly what was said through the machines, even when Mr. Drawbaugh talked in a whisper. George Frederick testifies that he was at Drawbaugh's shop with Mr. Hamme and Mr. Fry in January or February, 1876, and saw the talking machine. S. S. Rupp testifies that he was at Drawbaugh's shop with Mr. Hammacher and his scholars on February 1, 1876, and recollects that Mr. Drawbaugh at that time spoke about a machine that he had which he called a talking machine, but the witness was interested in other things, and did not pay much attention to it. George H. Bowman testifies that he saw talking machines in Drawbaugh's shop in February, 1876, at which time somebody was talking to Mr. Drawbaugh through them. Charles L. Drawbaugh testifies that he saw and talked through the talking machines at Drawbaugh's shop a year or more prior to May 1, 1876, and heard and understood what was said.

(TO BE CONTINUED.)

COMPANIES' MEETINGS.

The Consolidated Telephone Construction and Maintenance Company (Limited).

An extraordinary general meeting of the shareholders of this Company was held at the offices of the Company, 109, Farringdon-street, on Tuesday last, for the purpose of confirming the resolutions passed at the adjourned third ordinary general meeting, held at the Cannon-street Hotel, on Tuesday, the 16th December, 1884. Mr. C. L. W. Fitzgerald occupied the chair.

The SECRETARY (Mr. Charles Curtoys) read the notice calling the meeting and the resolutions which had to be confirmed.

The CHAIRMAN: Gentlemen, before I put these resolutions for confirmation to the meeting, I should like to say a word or two on the subject of the River Plate and Austria. Mr. Powers, our manager at the River Plate, has arrived in England, and, from conversations I have had with him, he has entirely altered that which I thought possible, namely, that there was a chance of strong opposition there against us. Now, on the contrary, I believe the opposition is anything but strong; and the reason I think why that is so is this, that some eighteen months ago a proposition was made to amalgamate the two companies on the basis of 33 per cent. to our business against 66 per cent. to theirs. That was declined. We, on our side, proposed amalgamation on the basis of one-half. The opposition declined that. Later on the opposition came to us and offered to amalgamate on the basis of one-half. We say "No, we will amalgamate with you on the basis of gross receipts," and to my mind that seems the fairest way that we could possibly settle the question. The business appears to be flourishing, and we keep on getting in fresh subscribers. I am informed that this morning we have got in Monte Video seven fresh subscribers, and that at £12 is a nice little sum. Well, I will now proceed to say a few words on the Austrian business. In July at the meeting in Cannon-street we told you that we should make that business a paying one if you would give us some more money to do so. I have here at this moment the latest return for Austria. The manager writes: "We have now a surplus of receipts over maintenance of about 10,000 florins"—that means £800 in round numbers, I believe. But we have still a certain number of gentlemen out there waiting for telephones to be put up, and each telephone that we put up will be a source of revenue. Of course you cannot put up a wire and erect a telephone to join these various subscribers without money, and as a means of getting that money to convert those gentlemen into a source of revenue, the Board propose to issue some debentures of the Austrian Telegraph Company, and very possibly offer them to some of the shareholders. I should tell you that each day that I know anything about the Austrian Company strengthens my belief that we have a very valuable property there. A concession in nine towns which have—I think I am near the mark in saying—nine of them under 30,000 inhabitants, and some ranging up to 300,000, is a very valuable concession, and in course of time I look to receive a very large income from that Austrian business.

The resolutions were then put to the meeting and confirmed, which terminated the proceedings.

NOTES.

TELEGRAMS FOR CEYLON.—The Post Office circular of 13th January states that the cable between India and Ceylon is interrupted.

NEW YEAR'S WISHES.—One of our contemporaries in the gas interest wished its readers "More Light." We re-echo the wish in a slightly extended form—"More and Purer Light."

SOCIETE GENERALE DES TELEPHONES.—The paid-up 375f. (£15) shares in this company were quoted at 390f. on 5th January, but fell to par on 12th January, and are now down to 370.

ANNUAIRE DU BUREAU DES LONGITUDES.—The edition of this publication for the present year contains, for the first time, tables of electric units, &c., in constant use by electricians.

THE TELEPHONE IN MEXICO.—On 1st November, 1884, there were 560 subscribers to the Telephone Exchange of Mexico, which city contains 250,000 inhabitants. At Guadalajara the Mexican Company now numbers 158 subscribers.

THE TELEGRAPH IN PERSIA.—Referring to our note of last week, the *Standard's* Teheran correspondent telegraphs that the Russians are already laying the line from Askabad to Merv, but that there had been a heavy fall of snow throughout Persia.

THE INVENTIONS EXHIBITION.—The Council of the Society of Arts announce that, under the Howard Trust, they will award gold medals for best exhibits in certain classes, amongst which is one in class 72, group 13, "Electricity"—distribution and utilisation of power.

ELECTRIC LIGHT IN PARIS.—The electric light is to be used during the construction of the new buildings to be erected at the Saint-Lazare or Western Terminus, Paris; and it is thought likely that arrangements will be made for electrically lighting them when complete.

THE FOUNTAINS AT THE HEALTHERIES.—*Electricité* of last Saturday publishes a good representation of the luminous fountains at the recent Health Exhibition, of course minus the beautiful and ever-varying hues, which constituted one of the chief features of Sir Francis Bolton's fairy creation.

ALTERNATE-CURRENT MOTORS.—The conclusions arrived at by M. E. Hospitalier in an article on this subject in *L'Electricien* are that alternate currents may produce work like continuous currents, whether at uniform or variable speeds; but, in both cases, alternate currents are less convenient and economical than continuous currents.

ELECTRO-TECHNOLOGY.—A course of fifteen lectures, interspersed with practical demonstrations, will be given at the University College, London, by Dr. J. A. Fleming, on "Modern Application of Electricity in the Arts." The introductory lecture is fixed for February 6; and the lectures will be continued every Friday at 4 p.m.

ELECTRIC LIGHT FOR BURNTISLAND HARBOUR.—At the monthly meeting of the Burntisland Harbour Board the harbour engineer, Mr. R. Henderson, brought up a report on lighting the harbour by the electric light, with motive power furnished by a Crossley gas engine. The report was favourably considered, and was handed over to a committee.

LONG-DISTANCE TELEPHONY.—The French Minister of Posts and Telegraphs, M. Cochery, lately assisted at some experiments in telephoning, on the Van Rysselberghe system, over the telegraph wires between Rouen and Havre. These experiments were not so satisfactory as those in Belgium and Portugal, probably because the distance was too great.

ELECTRIC LIGHT AT HAMMERSMITH.—The West Middlesex Electric Lighting Company announces that it is prepared to receive proposals for the execution of the first section of its works authorised by the Fulham District Order, 1884. Plans and particulars are to be obtained from the secretary, Mr. W. G. Colley, Caxton House, The Grove, Hammersmith.

PERSONAL.—The Administrative Council of the Societé de Crédit Mobilier has been strengthened by the addition of M. Duchâteau, who took a large part in the composition and management of the Societé Générale des Téléphones, and also in the first telephone lines of Italy and Belgium, besides turning his attention to electric lighting and the electrical transmission of power.

ELECTRICAL ENGINEERING PRACTICE.—The course of instruction at the Engineering School, University College, Nottingham, includes practical work in pattern making, moulding, fitting, turning, erecting, &c., as well as the College Lectures. Students are allowed to construct lathes and engines for themselves; and electrical engineering students are employed in the construction of dynamos.

PROGRESS OF ELECTRIC LIGHTING IN PARIS.—This, unfortunately, is in the wrong direction; *mais nous verrons bien.* The Jablochkoff candles have disappeared from the Avenue de l'Opéra; and one or two theatres that were electrically lighted have ceased to be so—for the time being. The Hippodrome, however, and most of the large drapers' shops—*magazins de nouveautés*—stick to the pure light.

THE EXCHANGE TELEGRAPH COMPANY AND THE STOCK EXCHANGE.—The question as to the value of the tape system in Stock Exchange transactions is still being discussed in the money columns of our contemporaries. We understand that a meeting was arranged to take place yesterday (Friday) between the directors of the Exchange Telegraph Company and the managers of the Stock Exchange.

ELECTRIC LIGHT IN CORN MILLS.—Messrs. Bowyer and Priestley, Offord Cluny, Hunts, who have adopted all the latest improvements for grinding corn and dressing the flour, have, for nearly two years past, lighted their large corn mill with incandescent lamps, the dynamo being driven by the mill engine. This change from candles and oil lamps to a better and above all safer light has given the greatest satisfaction to all concerned.

ELECTRIC LIGHT AS A BEACON.—In the dark days of December two students staying with the Bishop of Durham at Auckland Castle started off in the after part of the day for a walk to high ground about four miles distant. Darkness overtook them, and, being strangers to the district, they were quite at a loss to find their way back, until the arc lamp at the top of Duff and Rowntree's premises shone out, and by its assistance they were able to find their way home easily.

PHOSPHOR BRONZE WIRE.—With reference to our note on 3rd January, with reference to the breaking of telephone wires in a storm at Brussels, we learn that the wire so favourably reported on by M. Emile Bède, as resisting the violence of the gale and remaining unchanged by climatic influences, is of *bronze-phosphoreux*, made at the Fonderie d'Anderlecht, Brussels, by M. Montéfiore-Lévi, and of which the agents for the United Kingdom are the Western Electric Company, of Moorgate-street, E.C.

FRENCH EDISON COMPANY.—The Société Electrique Edison has lately installed 100 lamps, worked by a high-speed Gwynne

Digitized by Google

motor, for the Crédit Foncier, and also 100 additional lamps at the Hôtel de Ville. In the provinces, 50 lamps have been put up at the Poudrerie Nationale de St. Ponce, in the Ardennes; 25 lamps at the dye works of Champyron et Chavanne frères, St. Etienne; 50 lamps at Lyons, *chez* Chavaut; and 200 lamps at the paper mills of Outhenin-Chalandre, Geneuille, Doubs.

SILVER VOLTMETER.—To measure an electric current, the cathode is a platinum cup, and the anode a silver leaf enclosed in filtering paper. The anode is immersed in a solution of nitrate of silver contained in the cup; and an ampere deposits 4 grammes (62 troy grains) of silver per hour. It therefore suffices to allow the current to pass through the voltmeter for half an hour or an hour, in order to obtain a deposit of silver, which may be weighed correctly by an analytical chemist's balance.—*Electricité.*

LECTURES ON ELECTRICITY IN PARIS.—For some time past, the question has been under consideration of adding a course of lectures on electricity to the instruction given at the Ecole Centrale des Arts et Manufactures. Among the electricians capable of filling the new chair of electricity, the names have been mentioned of M. Hospitalier, Professor at the Ecole Municipale de Physique et de Chimie; M. Monnier, laboratory director of the Association pour l'étude de l'Electricité; and M. Géraldy, late Ingénieur des Ponts et Chaussées.

ELECTRIC LIGHT AT THE BRIGHTON PAVILION.—On Saturday evening the Brighton Town Council threw open the Pavilion to public inspection, when about 700 persons visited the apartments to view the electric light. The illumination was maintained with great steadiness, and general satisfaction was expressed. The pure light also showed off to great advantage the fresh decorations in the north drawing room. In the evening the corporation organist, Mr. Alfred King, gave a recital in the music room on the restored chamber organ.

THE LIGHTING OF THE CITY.—Some time ago we mentioned that the Hammond Company had been selected to light some of the City streets. This information is now confirmed, and the Commissioners of Sewers have accepted the contract for the lighting of Old Broad-street, front of Mansion House, Royal Exchange-buildings, Bartholomew-lane, Lothbury, Princes-street, Lombard-street, Birchin-lane, Bishopsgate-street Within, Throgmorton-street, Threadneedle-street, and Gracechurch-street. The decision was arrived at with closed doors.

ELECTRIC LIGHTING OF THE "EXMOUTH."—The following recommendation of the "Exmouth" Training Ship Committee was adopted by the Metropolitan Asylums Board:—"That the committee be authorised to invite schemes and tenders for lighting the 'Exmouth' by electricity; and, when such schemes and tenders are received, to consult a competent engineer with the view of obtaining his advice as to what additional boiler power it will be desirable to provide for this and other purposes connected with the administration of the ship."

ELECTRICITY ON BOARD SHIP.—It is stated that exhaustive experiments, with a view of determining the relative cost of oil, gas, and electricity for lighting ships of war, are about to be instituted by the Admiralty, on board the "Colossus," at Portsmouth. We are of opinion that such experiments as these are utterly out of place, and lead to a large expenditure of money without any adequate return. The question is not so much whether oil, gas, or electricity is the cheapest, but which is best for the purpose in view—that is to say, for purposes of warfare

ELECTRICALLY-LIGHTED SUBWAY FOR THE CITY.—On Tuesday last the Commissioners of Sewers had under consideration the proposal of Mr. H. H. Bridgman for the construction of a system of subways for the relief of the passenger traffic in the neighbourhood of the Mansion House. The scheme consists of a central subterranean chamber, surmounted by a skylight and four radiating subways, lined with glazed bricks. It was stated that a proposal had been received for electrically lighting the subways. The matter was referred to the Streets Committee.

ELECTRICAL ENTERPRISE IN FRANCE—*Electricité*, which has dropped the definite article beginning its former title, says that the year just past has not been among the most favourable to the development of electrical applications in France, most of the companies formed for working the discoveries of the new science having felt the rebound of the commercial crisis. Thus, stagnation in electrical affairs has been general; and the movement which seemed to be considerable after the first electrical exhibition, held at Paris in 1881, has produced but indifferent results.

JABLOCHKOFF AND GENERAL ELECTRICITY COMPANY.—This company has been registered, with a nominal capital of £20,000, divided into 200 shares of £100 each, for the purpose of purchasing the whole of the Jablochkoff patents, with the stock and goodwill as a going concern of the late Jablochkoff Electric Light and Power Company. Sufficient capital has been subscribed privately, and the purchase contract has been confirmed by the Court of Chancery. Mr. Francis R. Reeves has been appointed secretary and manager of the new company, whose registered offices and works are at No. 36, Albert Embankment, Lambeth, London, S.E.

ELECTRIC LIGHTING IN THE ISLE OF BUTE.—Mount Stuart House, the new family mansion which has been built by the Marquis of Bute, is to be lighted throughout by electricity, and cables for about 400 incandescent lamps are already fixed. Mr. Massey, of Thyford, having charge of all the arrangements. The cost of the building is put at £700,000 by one authority, and £750,000 by another; but it will probably reach nearly a million before the work is completed. Lord and Lady Bute, the family, and servants have been living in parts of the house for some time, and they use a large number of lights daily; so do the builders, who are working early and late to get the place finished.

ELECTRIC RAILWAY CONSOLIDATION IN NEW YORK.—Sir William Thomson has been invited to occupy the post of consulting electrician, and has agreed to do so provided he is not required to leave England. Some of the talk is rather tall as to the saving of coal, &c.; but the principal feature, viz., the absence of smoke and steam on the elevated railways seems to have been overlooked. It has been suggested that each competitor shall have one day's trial in drawing a train; but, if this be carried out, the result of the trials will not be worth much, as the best machine might be out of adjustment the first day and the worst happen to run all right. To have any real value each separate trial should extend over a reasonable period.

INTERESTING FIND BY THE HAMMOND COMPANY.—On Tuesday evening, while the electricians employed by the Hammond Electric Light Company were engaged in the underground cellars of the Mansion House, fitting up the wires for the electric light to be used in the Egyptian Hall and saloon, a skull and a number of human bones, together with those of some animal, were found under a flagstone which it had been

Digitized by Google

necessary to take up. The remains were discovered lying 2ft. below the surface, and, in the opinion of the authorities, they must have come from the adjoining burial ground of St. Stephen's, Walbrook, long since fallen into disuse, as their condition showed that they had been a considerable time underground.

PUBLIC TELEPHONE RATES IN FRANCE.—A decree of the President of the French Republic, signed on 31st December, 1884, by M. Jules Grévy, and countersigned by M. Cochery, Post and Telegraph Minister, fixes the rates to be levied for telephonic communication between the public at a "call" office and a subscriber or a non-subscriber at another "call" office. The rate for five minutes' conversation in Paris is 50 centimes (5d.), and in the other towns of France, Algiers, or Tunis, half that amount. The rate for five minutes' conversation between two separate towns is fixed at 1 franc (10d). for any distance less than 100 kilometres or 62 miles. This charge may be reduced to one-half when the two towns have been classed by the Post and Telegraph Minister as forming part of one and the same telephone group.

ELECTRIC LIGHTING AT HATCHETT'S.—The celebrated hostelry so long known as the White Horse Cellar has been entirely rebuilt, and will be reopened to the public on Monday next. With the sole exception of the bed rooms and private sitting rooms, which are to be lighted by time-honoured wax candles, the whole of the illumination will be effected by Edison electric lamps, variously applied. The current is supplied by the latest form of Edison dynamo machines, driven by two Otto gas engines of 12 horse-power nominal, the whole plant being in duplicate, to provide against accident. Messrs. Verity and Sons have put up the plant, the engine room having been specially constructed by Mr. John Waldram, C.E., superintendent of the entire works. The lighting of the dining room will be from the tables alone.

THE TELEPHONE COMPANIES.—Commenting on our remarks in last week's summary for 1884, relating to the defects of the telephone system, the *Pall Mall Gazette* says:—"If *The Electrician* had its way in the framing of a policy with regard to the telephonic interests of the country it would suggest the compulsory purchase of private interests by the State, the extension of underground wires, the lowering of rates, and the opening of every telegraph office as a telephone office." "But," continues the *Pall Mall*, "having had a lesson of the dog-in-the-manger policy which results from State monopoly in the telegraphs, remembering, too, that invention flourishes best when fanned by keen competition, and seeing that the telephone is in its infancy, most people will probably prefer that commercial freedom and a healthy competition should rule the roast longer yet." We fancy that "most people" here referred to does not include the telephone companies themselves, nor their customers, nor the public at large; but stands chiefly for newspaper theorists. Next week, however, we hope to be able to argue the point more fully.

NEW SINGLE-LIQUID BATTERY.—In the new battery of Buchin, Tricoche et Cie, a rod of amalgamated zinc forms the positive, and several rods of carbon the negative pole, the liquid being a weak acid or basic solution, such as that of sulphuric acid, of a bisulphate or acid sulphate, of hydrochlorate of ammonia, or of sea salt. The carbon is said to be so modified all through its substance during manufacture that hydrogen cannot accumulate on its surface; but the gas is obliged to pass off as generated, thus avoiding polarisation. This new battery, the E.M.F. of which is 1·15 volt, is claimed to be capable of working for an almost indefinite period, so long as the liquid lasts, to occupy little space, to be of easy management, and to be cheap, both in first cost and maintenance. It has, however, a high internal resistance when required to give out a large quantity of current, as in the case of electric lighting. This is attributed by the inventors to the fact that the hydrogen, on being disengaged, in raising up the carbons forms a layer of gas which opposes the current. They hope, however, to be able in time to counteract this disadvantageous action.

CARBONS FOR ELECTRIC ARC LIGHTS.—Carbons for arc lights may be made, says a well informed writer, by thoroughly incorporating a mixture of finely divided carbonaceous materials, such as the purer forms of coke, or gas retort carbon, with some liquid substance, such as oil, tar, or sugar syrup, that, when subjected to a high temperature, is capable of being carbonised. The finely divided ingredients are thoroughly mixed and made into a stiff paste with the carbonisable liquid, and then forced by heavy hydraulic pressure through circular apertures in plates. The continuous cylindrical rods thus obtained are cut into suitable lengths, carefully dried, and then heated to incandescence in ovens while out of contact with air. By this process the carbonisable liquids are reduced to a carbon, which thoroughly binds together the various ingredients. Experience has shown that the higher the temperature and the greater the length of time during which the carbons are subjected to the baking process, the greater their hardness and the higher their electrical conductivity. In order to ensure freedom from slight porosity, in most cases the carbons are subjected to a re-baking. After removal from the oven they are soaked in strong syrup, and again placed in the oven and heated to incandescence as before.

LONG-DISTANCE TELEPHONY.—In commenting on the three systems of long-distance telephony, the *Bulletin Internationale des Téléphones* says that M. Van Rysselberghe's plan utilises existing telegraph wires, and permits of the simultaneous transmission of telephonic and telegraphic messages, while diminishing the speed of the latter. That inventor has succeeded in diminishing the effect of induction; but he has not entirely suppressed it, while, however, preserving a sufficiently clear perception of the oral message. On the other hand he cannot telephone to advantage over greater distances than 80 kilometres, or 50 miles. The Herz method is also founded on the use of telegraph wires, and ostensibly neutralises induction; but the transmission of speech is effected with difficulty when the wires are being used for telegraphing. If it may be applied to long distances, conversations are not distinct in such a case. As to the third system, of double wire twisted, perhaps more scientific than the others, and the only one used in England and America, where it transmits for distances of 125 kilometres or nearly 80 miles, a special line is required, entailing greater expense; but there is every interest in keeping wires exclusively for telephoning. Our contemporary, therefore, very properly gives the palm to the last-named system, as that which best neutralises induction and affords a good exchange of communications.

ATTRACTION OF BODIES IN SOLUTION.—M. J. Thoulet is convinced that when a solid body is immersed in a salt solution, an attraction independent of chemical action is set up. The following is one of the experiments which have led him to this conclusion:—Grains of quartz, glass and marble, screened so that the diameter of the coarse particles is 0·9mm., and that of the fine 0·15mm., were immersed in iodine solution contained in three long and narrow tubes. Equilibrium was

Digitized by Google

established by the addition of water; the tubes were hermetically sealed and then placed in a vessel filled with water, for avoiding rapid variations of temperature. Supposing the grains to be spherical, the volumes vary as the cubes of the radii, while their surfaces vary as the squares of the radii; for an equal volume the surface would, therefore, be proportionally greater for a small than for a large grain. If the attraction exerted by the immersed solid on the body in solution be effected in direct ratio from the surface of the immersed solid, it will be impossible to float the large and small grains simultaneously. If the large float, the small behave as if they were heavier—that is to say, they fall to the bottom. This is proved by experience, except in the case of marble, all the grains of which, according to the density of the liquid, rise or fall at the same time, because, as these grains are porous, their surfaces are nearly proportional to their volumes.

Western Electric Company.—The specialty of this company is the manufacture of all apparatus pertaining to the telephone. Being sole manufacturers to the American Bell Telephone Company, and, through its Continental branch, to the International Bell Telephone Company, its instruments are in great demand. Through its London warehouse—in Moorgate-street, E.C.—it is enabled to meet promptly large demands for magneto bells, switch-boards, annunciator drops, and all other accessories of telephone exchange apparatus. Perhaps the most important improvement in telephone service during the past year has been effected at Liverpool by the introduction of the "multiple switch-board," which has been much approved by the Exchange subscribers and the directors of the company, owing to the great increase of speed in working, with corresponding reduction in the number of operators. In no other Exchange in England, probably, are 1,000 subscribers worked by 10 operators, with an average time for connections of 14 seconds. Improvements effected in the multiple board during the past year still further increase the speed of working and reduce the number of operators required. This company has lately introduced a new magneto bell, now turned out in large numbers from the Antwerp factory; and Patterson's patent anti-induction cable has been in great demand among trans-Atlantic companies, while last year some miles of it were laid down in Melbourne with the best results.

Failure of an Electric Bell.—On Saturday night the Great Northern down express from London to Manchester, which is timed to leave King's-cross at 6:15 and to reach Manchester at 10:45, had an extraordinary escape near East Retford. At Ordsall-lane is an ordinary level crossing, where the signal of approaching trains is given by electric bell from a signal box about half a mile distant. On Saturday night the attendant at this crossing received the signal for an up goods train, which he duly passed. At this moment a cart containing five men, who lived at Morton-grange, and who had been attending the Retford Market, was waiting to cross the line, and as soon as the train had passed, the attendant, having received no signal of an approaching train, opened the gates and called to the man in the cart to cross. The horse had just placed its feet on the rails when the express was seen under the bridge on the Great North-road, only 300 yards distant. The attendant shouted to the driver and seized one of the gates to throw it back, but as he was doing so, the express dashed past and smashed one of the gates into splinters. Strange to say the man was not hurt. The express pulled up at Retford, where on examination it was found that one of the lamps was gone, and this was subsequently picked up in a field adjoining the crossing. One of the vacuum brake pipes was also smashed. It was subsequently discovered that the electric bell at the signal station of the level crossing was out of order, and thus had not responded to the signal given by the signalman. Had the train been two or three seconds later the results would probably have been very serious.

Large or Small Dynamos?—In a work on the electrical transmission of power, M. Marcel Deprez and M. Japing state that a great many problems connected with this subject may be solved with the machines already constructed and the means actually at command, and also that the future is to large machines. Commenting on this, the *Bulletin International des Téléphones* observes that electric lighting experiments in England and Austria with alternate-current machines do not appear to have settled the question; Edison with his continuous-current machines does not seem to have exceeded 40 or 50 horse-power, a long way off 200 horse-power; and M. Marcel Deprez's experiments at Creil have special interest in this connection. Our contemporary, however, asks if, in every respect, large machines give comparatively better results than small. It is intended that the generating machines at Creil shall weigh from 35 to 40 tons for a current of 7,500 volts and 20 amperes, equal to 200 horse-power at starting. The receiving machines at Paris will weigh from 7 to 8 tons, and communicate to the shaft an available work of 30 to 35 horse-power, whence it follows that the weight per horse-power will be about 175 kilograms (3½cwt.) for the generator, and 200 kilograms (nearly 4cwt.) for the receivers, under the most favourable conditions. Now, in the present machines, such as the Gramme, for instance, the weight per horse-power does not attain 40 or 80 kilograms (rather over 7½ or 15 cwt.), according as they are used as generators or receivers. Therefore, the mean weight of matter per horse-power in large electrical machines will greatly exceed that of small machines. Here is a contradiction not generally met with. But, adds the *Bulletin*, this is not the first time that electricity quits beaten paths; and such small details will be no bar to ultimate success.

National Telephone Company.—We have been favoured by Mr. A. R. Bennett, general manager for the north of England and Scotland to the National Telephone Company (Limited), with a series of the new stamps adopted by the company for the payment of messages from non-subscribers throughout their districts; and we are glad to learn that the receipts for these "fee" messages (as they are called) from non-subscribers using the call offices in Edinburgh, Dundee, and Aberdeen, are already considerable. The head on the stamp is that of Colonel R. Raynsford Jackson, the chairman of the National Telephone Company, and the system is as follows:—In each call office will be found a pad of forms divided into oblong spaces, numbered from one to fifty. A subscriber to the company's exchange system, being entitled to use the call office gratis, will be required to sign his name in the next vacant space whenever he avails himself of the privilege; but a non-subscriber will be required to attach telephone stamps to the value of his conversation—not the intrinsic value, of course—in the next vacant space. The tariff being (for conversations with subscribers situated within six miles of the Chief Exchange of any town worked by the National Telephone Company) 3d. for every three minutes, and 1d. for each additional minute, a conversation lasting three minutes would require the attachment of a 3d. stamp to the form, one lasting four minutes a 3d. and a 1d., one lasting six minutes two 3d., &c. When the fifty oblong spaces have been filled with stamps or signature, the form is removed by the attendant, and a fresh one exposed.

Digitized by Google

The forms constitute a simple method of checking the company's receipts, in order to arrive at the amount of the Government tax of 10 per cent. The present series of stamps consist of 1d., 3d., 6d., and 1s., but a 4d. and a ½d. will shortly be added, and the stamps are on sale at the company's head office and also at all the call offices. The system was invented and the stamps were designed by Mr. A. R. Bennett, the company's general manager for Scotland and the North of England.

MAGNETIC OBSERVATIONS AT KEW.—The report of the Kew Committee for the year ending 31st October, 1884, contains the tabulated results of the deflection and vibration observations made at Kew between October, 1883, and September, 1884. They were all made by Mr. T. W. Baker with the collimator magnet marked K C 1, and the Kew 9in. unifilar magnetometer by Jones. The declination observations were also made with the same magnetometer, collimator magnets 101 B and N E being employed for the purpose. The dip observations were made with dip-circle barrow No. 33, the needles 1 and 2, 3½in. in length, only being used. The results of the deflection and vibration observations give the values of the horizontal force, which, being combined with the dip observations, furnish the vertical and total forces. They are expressed in both English and metrical scales—the unit in the first being one foot, one second of mean solar time, and one grain; and in the other one millimetre, one second of time, and one milligramme, the factor for reducing the English to metric values being 0·46108. By request, the corresponding values in C.-G.-S. measure are also given. The value of log $\pi^2 K$ employed in the reduction is 1·64365 at temperature 60°F. The induction coefficient μ is 0·000194. The correction of the magnetic power for temperature t_0 to an adopted standard temperature of 35° F. is $0{\cdot}0001194\,(t_0 - 35) + 0{\cdot}000{,}000{,}213\,(t_0 - 35)^2$. The true distances between the centres of the deflecting and deflected magnets, when the former is placed at the divisions of the deflection-bar marked 1·0 foot and 1·3 feet, are 1·000075 feet and 1·300097 feet respectively. The times of vibration are each derived from the mean of 12 or 14 observations of the time occupied by the magnet in making 100 vibrations, corrections being subsequently applied for the torsion-force of the suspension-thread. No corrections were made for rate of chronometer or arc of vibration, these being always very small. The value of the constant P, employed in the formula of reduction $\frac{m}{X} = \frac{m'}{X'}\left(1 - \frac{P}{r_0^2}\right)$, is −0·00129. In each observation of absolute declination the instrumental readings have been referred to marks made upon the stone obelisk erected 1,250 feet north of the Observatory as a meridian mark, the orientation of which, with respect to the magnetometer, was determined by the late Mr. Welsh, and has since been carefully verified.

ELECTRICITY FOR THE ELEVATED ROADS, NEW YORK.—Professor Moses G. Farmer has furnished Mr. Cyrus W. Field with an estimate of the cost of operating the Second Avenue Elevated Railroad of this city by electricity, as compared with steam. He says:—I assume that a stationary plant can be erected somewhere near the middle of the line, not far from Sixty-third-street, this plant to consist of one or more stationary steam engines of the best type, capable of developing one horse-power by the combustion of 1¾lb. of coal per hour per horse-power, by the use of such coal as does not cost over 2 dols. 50 cents per ton of 2,240lb. I assume that there are in use on this line twenty locomotives of 110 horse-power each at the busiest hour of the day, and that each locomotive consumes—per horse-power per hour—5lb. of coal that costs 4 dols. per ton of 2,240lb. I assume that the rails now in use are of steel, and weigh 70lb. per yard, and that a central steel rail of 70lb. per yard will be laid for the purpose of conveying the electric current to the motors. I assume that one mile of such steel rail will offer about 1-20 of an ohm resistance, and that the aggregate internal resistance of the dynamos concerned in producing the current will not exceed 1-200 of an ohm. I assume that from this central station sufficient current will be supplied to both tracks to energise at the same instant all of the twenty electric locomotives, no matter on what part of the tracks these motors may be situate. I assume that 1 horse-power is the equivalent of 746 ampere-volts, and that 20 by 110 by 746 = 1,641,200 ampere-volts, in the aggregate, reach these motors. I assume that such dynamos can be constructed as shall convert 90 per cent. of the mechanical power applied to them into current electricity, and I also assume that such electric motors can be constructed and used as shall convert 90 per cent. of the electricity that they receive into power used to draw the trains that are attached to them. I assume the Second Avenue Railroad to be six and a half miles in length. With these assumptions, I have calculated the following tables:—

TABLE I.

Volts.	Present power.	Future power.
500	2,200	3,369
1,000	2,200	2,879
1,500	2,200	2,787
2,000	2,200	2,757

TABLE II.

Volts.	Present coal.	Future coal.	Saving per hour.
500	11,000	5,895	5,104
1,000	11,000	5,039	5,961
1,500	11,000	4,889	6,111
2,960	11,000	4,825	6,175

TABLE III.

Volts.	Present cost.	Future cost.	Saving per hour.
500	$19.65	$6.58	$13.07
1,000	19.65	5.62	14.03
1,500	19.65	5.46	14.19
2,000	19.65	5.38	14.27

Table 1, column one, contains the electromotive force developed by dynamos at the central station; column two contains the horse-power required by the 20 locomotives; column three contains the horse-power that must be used at the central station in order to deliver at the electric locomotives the equivalent of 2,200 horse-power. Table 2, column one, contains the electromotive force, as in the first table; column two contains the hourly consumption of coal by the 20 locomotives now in use—5lb. per hour per horse-power; column three contains the amount of coal consumed by the stationary engine that develops 1 horse-power by the combustion of 1¾lb. of coal per hour; column four shows the saving in lbs. of coal per hour made by substituting the better engine, the dynamo, the electric motor, and the rail circuit. Table 3 shows the hourly saving in dollars and cents by the substitution of electricity thus applied for the coal now used in the locomotives. It will be seen from this last table that the lower and safer electromotive force of 500 volts is only about 9 per cent. more expensive than the four times as great 2,000 volts, and about 7 per cent. more expensive than 1,000 volts. I must reserve for another letter my conclusions regarding what would be the saving resulting from the use of electricity on the Third Avenue line, as I wish to obtain some further information as to frequency of trains, &c.

WILLIAM GARNETT.

GARNETT, WILLIAM; born at Portsea in December, 1850. In January, 1863, he entered the City of London School, and was at first under the mastership of Mr. Thos. Hall, B.A., who did very much towards the development of scientific teaching in that school. In the May examination of 1866 he obtained the first Royal Exhibition, tenable at the Royal School of Mines and College of Chemistry, and during the winter session he studied under Dr. Frankland and Professor Tyndall, but in the following year resigned the exhibition and returned to the City of London School. In April, 1869, he gained the Exhibition for Natural Science at St. John's College, Cambridge, and in July of the same year the Beaufoy Mathematical Scholarship at the City of London School, and commenced residence at St. John's College in October. The following summer he was first in the competition for Sir Jas. Whitworth's Scholarship for Mechanical Engineering, and in 1871 was elected Foundation Scholar at St. John's College. In January, 1873, he took his degree as Fifth Wrangler (bracketted), and shortly afterwards, on the opening of the Cavendish Laboratory, he was appointed Demonstrator in Experimental Physics by Professor Clerk Maxwell. In November, 1874, he was elected Fellow of St. John's College, and retained his fellowship till his marriage in 1879. In October, 1876, he commenced to give public lectures in the Cavendish Laboratory, and continued to lecture there upon mechanics, heat, magnetism, and electricity, until Easter, 1880. In April, 1879, he was appointed by the Senate Examiner in Natural Philosophy in the University of London. Professor Clerk Maxwell died in November, 1879, and in the following month Lord Rayleigh accepted the Professorship of Experimental Physics. Mr. Garnett remained in the Cavendish Laboratory until Easter, 1880, when he declined to be reappointed. Shortly afterwards he was appointed Lecturer on Physics at St. John's College. In 1879, 1880, and 1881, he was one of the Examiners in the Natural Sciences Tripos. In April, 1882, the Committee of University College, Nottingham, invited him to accept the Professorship of Mathematics, Physics, and Mechanics.

Shortly afterwards he was appointed Electrician to the Corporation of Nottingham. He commenced work at Nottingham in October of the same year. During the following summer he organised a system of technical education in connection with the mechanical department of the College, and fitted up a complete set of engineering workshops, which were very largely attended by the artisan classes during last session. These workshops were formally opened by Sir Frederick Bramwell, F.R.S., on the 24th January last. Besides a complete plant of engineers' tools, the mechanical schools are furnished with dynamos and other appliances for students in electrical engineering, and the electric lighting of the Free Library by the Ferranti dynamo has been very successful. In November, 1883, Professor Garnett was appointed Principal and Professor of Mathematics in the Durham College of Science, Newcastle-on-Tyne, with the understanding that his full duties would not commence until the following October. He is now giving special attention to the development of technical education in the Tyneside district, and a scheme is on foot for the erection of a central college in which a University education will be provided for day students, while workshop and laboratory instruction, as well as theoretical training on scientific principles, will be given to those employed in the chief manufacturing industries of the locality. As the college represents the Science Faculty of the University of Durham, students passing successfully through its curriculum will be able to take degrees in science from the University.

Professor Garnett's treatise on Elementary Dynamics is now the acknowledged text book on that subject for candidates for the Mathematical Tripos. He is also author of an elementary treatise on Heat; a very Elementary Mechanics for the use of Higher Grade Schools, published by the S.P.C.K. at 4d.; a "Book of Trigonometry," intended specially for the use of candidates for the Cambridge Local Examination; and, with Professor Lewis Campbell, was joint author of the "Life of James Clerk Maxwell." Professor Garnett edited "Maxwell's Elementary Treatise on Electricity," the manuscript of which was left unfinished by the author. His lecture notes on Electricity, printed for the use of his students at Nottingham, occupy more than 100 pages, the first half of which formed the basis of the articles on elementary electricity which have from time to time appeared in the columns of *The Electrician*. His lecture notes on Heat and Astronomy, similarly prepared under the auspices of the Cambridge Syndicate for the Extension of University Teaching, form convenient summaries for students wishing to *revise* the subjects.

Garnett's Elementary Dynamics.

An opportunity is afforded us to call attention to a work which, like "Cumming's Electricity," is at once good, and insufficiently known. With regard to the former work, we have been surprised to find many men whose names stand high in the ranks of the electrical world totally unacquainted with the book; and during a somewhat long and chequered experience among educationalists the ignorance of many schoolmasters as to the good books published has seemed to us a bad sign. It may be said that Cambridge is the centre of mathematical activity, without fear of contradiction, but many books are exclusively used at Cambridge that do not seem to take their proper position outside the bounds of the University. In 1875, when Professor Garnet's book on "Elementary Dynamics" was issued, the present writer was editor of the *Journal of Education*, and therefore had good opportunities of hearing the opinions of those best qualified as to the promise shown in such a work. Almost without exception the criticisms were very favourable, and when qualified it was only to suggest the book to follow a more elementary one. The work commends itself, we think, to electrical engineers in many respects, not the least of which is the manner in which the question of "units" is discussed Our vulgar education makes us acquainted with English units. we use them in the shop and in the field; but our more refined education makes us acquainted with more refined methods, and usually a system of mental translation takes place whenever one of the more modern limits is mentioned in measurement. In conclusion, we may say that the engineering student, whether he desires to specially follow the civil, mechanical, hydraulic, or electrical branch of the profession, will find the fundamental laws of "Mechanics" admirably set forth in this little work.

ALTERNATING CURRENTS. — SELF-INDUCTION. GRAPHIC REPRESENTATION.

BY THOMAS H. BLAKESLEY, M.A.

It is often taken for granted that the simple form of Ohm's law—total E.M.F. ÷ total resistance = total current, is true for alternating currents. That is to say, the E.M.F. employed in the formula is taken to be the sum of the *impressed* E.M.F.'s alone. That there are causes which modify the value of the current as deduced from this simple equation, such as mutual or self-induction, or the action of condensers, is often acknowledged in text books, and the values and laws of variation of the current correctly stated for certain cases of instantaneous contact and breaking of circuit. But the effect of an alternating E.M.F. upon a circuit affected by self-induction, mutual induction, and condensing action, has not been, as far as I know, put into a tangible working form.* I propose to deal with the case where the impressed E.M.F. is subject to simple harmonic variation—that is to say, the sort of variation which takes place in the apparent distance of a satellite from its primary as seen by an eye situated in the plane of revolution, and at an indefinitely great distance from the orbit. The form of the law is simply $x = b \sin\left(\frac{\pi}{T}\overline{t - t'}\right)$ where t is the symbol for time, t' being the value at the particular epoch when x is zero, x representing the magnitude subject to the variation under consideration. Since the sine of no angle can exceed unity, b is the maximum value of x. T is half the period or the time required for x to vary from its greatest positive value to its greatest negative.

This sort of variation is exactly that which the E.M.F undergoes in the case of a coil, turned round any axis at a uniform rate in a uniform magnetic field, and is very approximately the case in a large number of motions occurring in practice. It is also the case when a small bar magnet revolves at the centre of a coil, exactly when the magnet is very small compared with the coil, and highly approximately in other cases. The variation of telephonic currents, as produced in a Bell telephone, is also harmonic.

As some of the problems involving alternating currents can be very well exhibited and solved by geometrical methods, I shall give one or two geometrical propositions which will render the diagrams that may occasionally be required easier of comprehension.

PROPOSITION I.

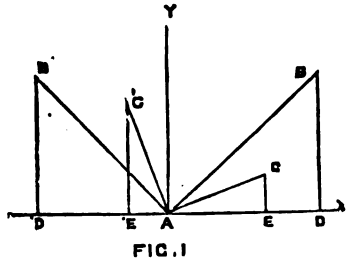

FIG. 1

If A B, A C, are two lines in the plane of A X, A Y, which revolve round a line drawn through A at right angles to this plane, at a uniform rate, the angle C A B being maintained constant, to find a geometrical expression for the mean value of the product of the projections of A B, A C upon A X,

From B and C draw B D, C E, perpendicular to A X.

Draw A B′ perpendicular to A B, and make A B′ equal to A B.

Draw A C′ perpendicular to A C, and make A C′ equal to A C.

Then A B′, A C′ represent the positions of A B, A C after revolving through one right angle.

Draw B′ D′, C′ E′ perpendicular to X A produced.

Then the angle A B′ D′ is equal to the angle B A D, and the angle A C′ E′ is equal to the angle C A E.

Now

$$\text{A E, A D} = \text{A C, A B} \cos \text{C A E} \cos \text{B A D},$$

and

$$\text{A E′, A D′} = \text{A C′, A B′} \sin \text{A C′ E′} \sin \text{A B′ D′} = \text{A C, A B} \sin \text{C A E} \sin \text{B A D};$$

therefore

$$\frac{\text{A E, A D} + \text{A E′, A D′}}{2} = \frac{\text{A C, A B}}{2}\left\{\cos \text{C A E} \cos \text{B A D} + \sin \text{C A E} \sin \text{B A D}\right\}$$

$$= \frac{\text{A C, A B}}{2}\left\{\cos \overline{\text{CAE} - \text{BAD}}\right\}$$

$$= \frac{\text{A C, A B}}{2} \cos \text{B A C}.$$

But the quantity upon the left of this equation represents the mean value of the product of the projection of A B, A C, upon A X, for two positions of the moving system differing by one right angle. And all the positions of the system may be taken in pairs differing by one right angle. But when two such positions are taken the mean value is shown by the above equation to be independent of the actual position of the system.

Therefore, the mean value obtained for two such positions is the mean value for all positions, and is given by the above equation, the right hand side of which shows it to be half the product of A B and A C multiplied by the cosine of the angle between them.

It is unnecessary that the lines A B, A C should have a common point. If A B, C D are any two lines situated in one plane, and inclined to one another at a constant angle, while they revolve round any axis at right angles to the plane containing them, the mean value of the product of their projections on any fixed line in the plane containing them is half the product of their lengths multiplied by the cosine of the angle between them.

The application of these propositions to problems in alternating currents is extremely simple.

Suppose one of the lines we have been considering represents the maximum value of an alternating electromotive force varying harmonically, and acting upon a circuit converging an alternating current also varying harmonically, and that the two have the same period. Suppose the second of the two lines to represent the effective electromotive force through the circuit at a maximum. Then the projections of these two lines may be taken to represent the real value of these two electromotive forces at some instant. If we divide the effective electromotive force by the resistance, we get the real value of the current at the instant, and the product of the electromotive force represented by the projection of the first line into the current at the instant represents the power at the instant exerted by the source of the electromotive force represented by the first line.

Hence, if in the figure A B represent the maximum value of some electromotive force acting upon a circuit whose resistance is R, and A C represent the maximum of the effective electromotive force producing current, then the mean power exerted by the source of electromotive force, whose maximum is A B, is equal to $\frac{\text{A B, A C}}{2\text{R}} \cos \text{B A C}$.

Now, suppose that the only two electromotive forces acting upon the resistance R are represented by A B, B C, when at their maximum, and by the projection of these lines upon any fixed straight line at any other point, then A C is the effective electromotive force acting upon the resistance R. Join A C, and produce it towards A to D, and draw B D perpendicular to it.

Then by what has been said the power exerted by the source of B C is $\frac{\text{B C, A C}}{2\text{R}} \cos \text{A C B}$, and the power exerted by the source of A B is $\frac{\text{A B, A C}}{2\text{R}} \cos \text{C A B}$.

This in the figure as drawn has a negative value, equal numerically to $\frac{\text{A B, A C}}{2\text{R}} \cos \text{D A B}$, which, therefore, repre-

* Dr. Hopkinson has quite recently dealt with some of the cases of alternating currents in a paper read before the Society of Telegraph Engineers and Electricians.

Digitized by Google

sents the power doing work upon the source of A B, and, following the same rule, the effective power sending the current through the circuit is $\frac{A C \times A C}{2 R} \cos 0 = \frac{A C^2}{2 R}$.

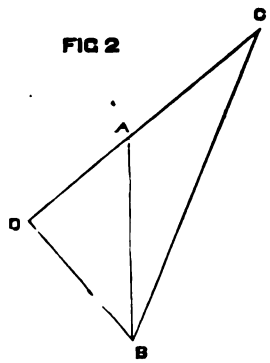

FIG 2

The three powers of the primary source, of the recipient source, and that heating the circuit, are proportional respectively to

B C cos A C B : A B cos D A B : A C, *i.e.*, to C D : D A : A C.

The electromotive force of self-induction is one which depends for its value upon the rate of increase or decrease of the current. It is greatest when the current is increasing most rapidly, *i.e.*, when the current is zero, and it is least when the current is unchanging, *i.e.*, when it is at a maximum or minimum. It varies therefore harmonically, and is in fact an electromotive force which must be drawn in such a diagram of electromotive forces as has been considered at right angles to the effective electromotive force. Its mean power, therefore, in a period must be zero.

To find its maximum value, consider that if 2 T is the complete period $\frac{2\pi}{2T}$ is the angular velocity of any point in the diagram. And if the diagram revolve round one extremity of the line representing the effective electromotive force, the greatest rate of increase of the effective electromotive force is represented by the velocity of the other point.

If e be the maximum value of the effective electromotive force, $e\frac{2\pi}{2T}$ will represent its greatest rate of increase, and this divided by the resistance R, will represent the greatest rate of increase of the current. If, therefore, the circuit has a self-induction coefficient of the value L, the maximum value of the electromotive force of self-induction will be $L\frac{e}{R}\frac{2\pi}{2T} = e\frac{L\pi}{RT}$; therefore, in the diagram $\frac{L\pi}{RT}$ must be equal to the tangent of the angle between the effective electromotive force and the resultant of the impressed electromotive forces.

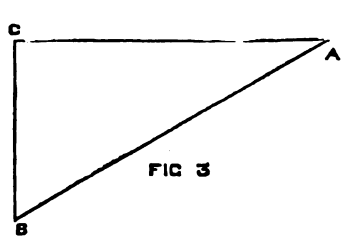

FIG 3

Thus, in the figure, if A B represent the resultant of the impressed electromotive forces, and A C is drawn so that tangent $C A B = \frac{L\pi}{RT}$, and B C is drawn perpendicular to A C, then B C represents the electromotive force of self-induction and A C the effective electromotive force.

Most problems relating to self and mutual induction and to the action of condensers at particular points may be treated geometrically in the way indicated, as will be exemplified occasionally in the following chapters, though the analytical method is probably better in cases of distributed capacity.

The electromotive force of self-induction, properly speaking, exerts no power in a period. It happens, however, that the cores of electro-magnets become warm when subjected to an alternating current, and this effect is generally attributed to the heat from the circuit reaching them by conduction. Some very high authorities have held that the power due to any induced electromotive force must be zero, and that the change of electro-kinetic momentum involves no loss of energy. It is certain that if there be any electromotive force doing work, its projection on the line of effective electromotive force cannot vanish; and if any work is done upon the cores by the changes of polarity in one period, the effective electromotive force will be diminished by the amount of one opposite to it in phase and of such a value that if multiplied by the reduced effective one and divided by twice the resistance, the result will be the power producing the work observed to be done upon the cores. Such an electromotive force is an induced one, but it differs from that of self-induction as usually understood in having its phase in exact opposition to that of the current. In such a case the diagram of electromotive forces would be as in the figure:—

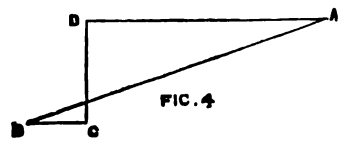

FIG. 4

Here A B is the impressed electromotive force.
A D is the effective electromotive force.
C D is the ordinary electromotive force of self-induction.
B C is the electromotive force resulting from magnetic viscosity, and D C, D A are connected by the relation

$$\frac{DC}{DA} = \frac{L\pi}{TR}.$$

The result of a large magnetic viscosity would be, therefore, to diminish the effective electromotve force in comparison with the impressed one, but at the same time to bring the two more nearly into the same phase; whereas the effect of an increase in the coefficient of self-induction, as commonly understood, is to diminish the effective electromotive force in comparison with the impressed one, and at the same time to increase the difference of phase.

(TO BE CONTINUED.)

THE ANTWERP EXHIBITION.—The date for receiving applications for space having expired, the managing committee is now busy with the work of distribution. The Austrian section will be decorated in mediæval style, embracing two wrought-iron gates, 4½ metres wide and 7 metres high, which were made in the reign of Charles VI. and now belong to the Imperial palace of Vienna. The 114,432 square metres of space, both roofed and open, are to be illuminated under the direction of a special electrical committee, who express a desire that all electric companies and all systems of electric lighting (both arc and incandescent) should be well represented. It is stated that all the Governments except those of Austria and Germany will be officially represented, for which countries, however, influential committees have been formed.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the weeks ended 2nd and 9th January, were £2,489 and £2,208 respectively (after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Company).

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the two weeks ended 2nd and 9th January amounted to £3,079 and £3,080 respectively.

THE PROTECTION OF SUBMARINE CABLES.

Extract from the "Bulletin Mensuel des Postes and des Télégraphes" (Monthly Bulletin of Posts and Telegraphs), No. 24, dated December, 1884. (Paris.)

[Translation.]

Law respecting the Repression of Infractions of the International Convention of March the 14th, 1884, relative to the Protection of Submarine Cables.

The Senate and the Chamber of Deputies have adopted, the President of the Republic promulgates the Law, the tenour of which is as follows:—

HEADING I.—*Special Regulations for Non-Territorial Waters.*

ARTICLE 1. Infractions of the International Convention of March the 14th, 1884—the object of which is to secure the protection of submarine cables—which may be committed by any individual forming part of the crew of a French vessel, shall be judged by the Correctional Tribunal, either of the district (*arrondissement*) in which may be situated the port to which the delinquent's ship belongs or of the district (*arrondissement*) of the first port of France into which the vessel may be taken.

ARTICLE 2. The prosecution shall be undertaken at the suit of the Public Ministry, without prejudice to the right of the civil parties.

ARTICLE 3. The minutes (*procès-verbaux*) drawn up agreeably to Article 18 of the Convention of the 14th March, 1884, shall not be subject to affidavit; they shall be held as proved until the requisite steps are taken to prove them false.

In default of minutes (*procès-verbaux*) or in the event of these deeds proving inadequate, the infractions may be proved by witnesses.

ARTICLE 4. Any one who may refuse to produce the documents requisite for drawing up the minutes (*procès-verbaux*) cited in the preceding articles, shall be liable to a fine of from 5 to 100 francs and to imprisonment for a term of two to ten days.

ARTICLE 5. Every assault, every resistance accompanied with violence and the use of force, against the persons qualified by the terms of Article 10 of the Convention of March the 14th, 1884, to draw up the minutes (*procès verbal*) in the exercise of their functions, shall be punishable with the penalties applicable to rebellion according to the distinctions established in the penal code.

ARTICLE 6. Shall be punishable with a fine of 16 to 300 francs:

1. The captain of a vessel who, engaged in repairing or laying a submarine cable, shall fail to observe the rules respecting signals adopted with the view of preventing fouling.

2. The captain or master of any vessel, who, perceiving or being in a position to perceive these signals shall fail to turn away (back) or to keep (himself) at least at the distance of a nautical mile from the ship engaged in laying or repairing a submarine cable.

3. The captain or master of any vessel, who, seeing or being in a position to see the buoys laid down to mark the position of the cables, shall fail to keep (himself) at the distance of at least a quarter of a nautical mile from the line of the buoys.

ARTICLE 7. Shall be punishable (punished) with a fine of 16 to 500 francs, and liable to imprisonment for a term of one to five days:

1. The captain or master of any vessel who shall have cast anchor within a quarter of a nautical mile of a submarine cable the position of which he is in a position to know by means of lines of buoys or otherwise, or shall have moored to a buoy laid to mark the site of the cable, except in cases of circumstances beyond control (*force majeure*).

2. The master of any fishing vessel who shall fail to keep his apparatus or nets at least one nautical mile from the vessel engaged in laying or repairing a submarine cable; fishing vessels, however, which perceive or are in a position to perceive the telegraph vessel shewing the signals adopted, shall, in order to comply with the signal warning, be allowed sufficient time to finish the operation in hand, such time however not to exceed 24 hours.

3. The master of any fishing vessel who shall fail to keep his apparatus or nets at least one quarter of a nautical mile from the line of buoys laid down to mark the position of the submarine cables.

ARTICLE 8. Shall be punished with a fine of 16 to 300 francs and liable to a term of imprisonment varying from six days to two months:

1. Whoever, through culpable negligence, and specially in the cases met by Articles 6 and 7, shall break a submarine cable, or shall cause an injury to it which may result in an interruption, or a hindrance, either entire or partial, to the means of telegraphic communication.

2. The captain of any vessel who engages in the laying or repair of a submarine cable, shall be the cause through inobservance of the rules as to signals adopted with the view of preventing fouling, of the breaking or injury to a cable committed by any other ship.

ARTICLE 9. Shall be punished with a fine of 16 to 300 francs, and liable to a term of imprisonment varying from six days to two months:

1. Whoever shall make, keep out of his house, put up for sale (sell), ship, or cause to be shipped, instruments or apparatus exclusively used for the purpose of cutting or destroying submarine cables.

2. Whoever shall make use of these instruments or apparatus.

ARTICLE 10. Shall be punished with a fine of 300 to 1,000 francs and imprisonment varying from three to five years, whoever shall voluntarily (intentionally) break a submarine cable or shall cause an injury to it which may interrupt or impede, either wholly or partially, the means of telegraphic communication.

The same penalties shall be pronounced against the authors of attempts of the same things.

The guilty party may in addition be placed under the surveillance of the high police for a maximum term of ten years, dating from the day he shall have suffered his penalty.

These regulations, however, do not apply to persons who may be compelled to break a submarine cable or to injure it through the actual necessity of protecting their lives or securing the safety of their ship.

HEADING II.—*Special Regulations for Territorial Waters.*

ARTICLE 11. The regulations of Articles 4, 6 to 10, as above set forth, shall be observed in the case of the infraction having been committed in our territorial waters by any individual forming part of the crew of any ship whatever, French or foreign, without prejudice to the provisions of Article 4 of the Decree of December the 27th, 1851.

ARTICLE 12. The infractions prosecuted agreeably to the terms of the preceding article shall be judged by the Correctional Tribunal either of the port to which belongs the vessel upon which the delinquent embarked, or of the first French port at which this vessel shall touch, or of the place of the offence.

ARTICLE 13. The infractions committed in our territorial waters shall be established (proved) by minutes (*procès-verbaux*), and in default of these by witnesses.

ARTICLE 14. The minutes (*procès-verbaux*) stipulated in the preceding Article shall be drawn up:

By the officers commanding any of the French men of war.
By any of the officers of Judiciary Police.
By any of the sworn officers of Municipal Police.
By the other functionaries enumerated in Articles 10 of the Decree of December the 27th, 1851, and 16 of the Decree of January the 9th, 1852.

Any assault, any resistance accompanied with violence or the use of force, against the agents qualified agreeably to the terms of the above regulations to draw up the minutes (*procès-verbal*) in the exercise of their functions, shall be punished by the penalties applicable to rebellion, according to the distinctions set forth in the Penal Code.

ARTICLE 15. The minutes (*procès-verbaux*) drawn up by officers commanding French men of war are not subject to affidavit: they are held as proved until the requisite steps are taken to prove them false.

The minutes (*procès-verbaux*) drawn up by all other agents qualified for the purpose agreeably to the terms of Article 14 have the force of proofs, and are subject to the formalities laid down by the Special Acts (Laws), particularly Articles 10 and 11 of the Decree of December the 27th, 1851, and 17 and 20 of the Decree of January the 9th, 1852.

HEADING III.—*General Regulations.*

ARTICLE 16. The delinquent in the case of Article 8, Clause 1, shall be bound, within 24 hours of his arrival, to give notice to the local authorities of the first port at which the vessel on which he is embarked shall touch, of the breaking of or injury to the submarine cable of which he may have been guilty.

In default of (such) declaration the penalties incurred shall be doubled.

In the case of Article 10, Clause 4, the author of the break or injury shall be bound, under penalty of a fine of 16 to 100 francs, to make the above declaration.

ARTICLE 17. In cases of second offence the maximum of the penalties announced above may be doubled.

There is second offence:

1. For the acts foreseen by Articles 6, 7, 8, and 9 of the present Act (Law), when in the two preceding years a definitive judgment has been given against the offender for infraction of the regulations of the said Articles.

2. For the acts foreseen by Article 10, when at any period whatever a definitive judgment has been given against the delinquent for infraction of the regulations of that Article.

ARTICLE 18. The parties who have fitted out the vessels, whether the owners or not, in virtue of the fact of fitting out these vessels, shall be declared responsible for the payment of the fines pronounced for the infraction of the present Act (Law) and for the civil condemnations to which these infractions might give rise.

The other cases of civil responsibility shall be settled agreeably to the Regulations of Article 1,384 of the Civil Code.

ARTICLE 19. In cases of conviction for several infractions foreseen by the present Act (Law), the heaviest penalty alone shall be pronounced.

ARTICLE 20. Article 463 of the Penal Code is applicable to the condemnations pronounced for infractions of the present Act (Law).

The present Act (Law), resolved and adopted by the Senate, and by the Chamber of Deputies, shall be executed as a law of the State.

Done at Paris, December the 20th, 1884.

JULES GRÉVY,
By the President of the Republic.

JULES FERRY,
President of the Council,
Minister of Foreign Affairs.

MARTIN FEUILLÉ,
Keeper of the Seals,
Minister of Justice and Worship.

A. PEYRON,
Minister of Marine and of the Colonies.

AD. COCHERY,
Minister of Posts and Telegraphs.

SPECIFICATIONS.

A subject which has provoked a considerable amount of discussion in our columns is that of paying for Specifications. The question has a much greater interest in the earlier stages of the development of any industry than later on. We are not quite sure whether the following statements with regard to the older industries are strictly accurate, but according to our examination they fairly describe the rule.

All ordinary business transactions, except in the case of strict monopolies, are the results of "open tender." We give our custom to one grocer in preference to another, for some such reason as convenience, cheapness, excellence of goods, &c. Every grocer offers his goods at a price, we make the selection. When we consider other industries a difference of procedure is discernible, but still we have the "open tender" system. Thus, in the building trade, for example, it is customary for the person who desires to build to advertise his desire, and select from among those who send in "tenders." The selection is sometimes partly made before the desire for tenders is advertised, giving us the system of "limited competition." This latter system is very general; sometimes, for example, the competitors are limited to a "district," sometimes to "manufacturers," sometimes the work is not advertised in the ordinary way at all, but half a dozen firms of repute are, by a more private method, asked to "tender."

The most common sense view of any business transaction is that a profit is to be made upon the work done. One firm may be satisfied with 10 per cent., another may want 15 per cent., a third will require 20 per cent. or more. We may take it for granted that any firm in sending in a tender has contemplated the acquirement of the percentage decided upon. The "cost price" of the work will differ for each firm, therefore there will be a variation in the amount of tender, even if the profit contemplated be the same in each case. Now, take any simple case, and suppose a charge made for the Specifications, and that each firm obtaining a Specification sends in a tender. Is it not clear at once that the cost of Specification is added on to the prime cost of work, and the tender is thereby increased by this amount and the interest thereon? The tender consists of prime cost + cost of specification + profit. A man must have had few dealings in business who thinks that the "profit" part of this amount will be decreased. The primary object of business is to make profits, and firms carried on with an honest hatred of the bankruptcy court will not do work without a profit. We know enough of more than one great industry to say that profits cannot be lowered in honest transactions. No firm has yet grown rich through its electric lighting work; nor are there any indications of superabundance of profits. Viewing the payment for Specifications in this light it will be seen that the purchaser has to pay.

There is now the second case, where all those who obtain Specifications do not send in tenders. At first sight it may seem that the purchaser obtains an advantage, but if closely examined it must be admitted that his payment is increased by the charge made. For those who are lucky enough to escape the intricacies of estimates, and may not be fully acquainted with the methods followed in business transactions, it may briefly be explained that a firm desires a certain income per annum. The firm has to pay wages—for materials, rent, rates, office expenses, such as for clerical work, paper, stamps, &c. If it is customary to pay for Specifications, the annual amount so paid will soon be averaged and be lumped with office expenses, a percentage of which will be charged on every tender sent out. These payments make up what are known as "constant" charges. Increasing the "constant" charges of an office thus means increasing *pro rata* every estimate. If the firm is not going down hill, these "constant" charges are recouped from the payments received for work done—in other words, the purchaser has to pay, just as he has to pay for materials and the profit of the contractor. The amount the purchaser pays is certainly an average, and may be, probably always is, more, instead of being less, than the actual cost of the Specification.

We state as a general proposition that in whatever way the "constant" charges of an industry be increased the result is the same—an increased price to the consumer. The aim of everyone connected with electric work should be to keep these charges as low as possible, and hence the introduction of the payment for Specification system has met with a well-deserved rebuff.

There are many arguments which might be brought forward, not only against the economy but against the expediency of such a system, and these arguments have tenfold more force when applied to a young and struggling industry.

In conclusion there are and must be exceptions to every rule, and there are exceptions to the non-payment for Specifications. The principal exception is when the drawings accompanying the Specification, or the matter contained in the Specification, are intrinsically worth the amount charged for them. It is almost needless to point out that the drawings of many a great engineering work would be cheap at a far greater cost than is paid for them, and many outsiders would gladly purchase them, or the Specification in which is concentrated the talent of several consulting and acting engineers. Frequently but few drawings are made, in order that things valuable in themselves, and containing information which individuals or companies desire to keep secret, should not by any chance come

Digitized by Google

into the hands of the public. When this is so, the purchaser of the Specification gets full value for his money, just in the same way as he would if he had purchased a valuable book. It is frequently the case that a schedule of quantities accompanies the Specification, for which a special charge is made. The providing of such a schedule does not exempt the contractor taking out his own quantities, but there is little doubt it saves him far more than the cost usually charged. We have not specially gone into those cases in which the amount charged is returned upon the receipt of a *bonâ fide* tender, as they are really included in the general argument.

CORRESPONDENCE.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the remarks of Dr. Stone (p. 188) upon my letter (p. 150), I must point out to him that my principal object was to correct the serious errors in Professor Dolbear's statements, so as to prevent these from passing uncontradicted through the Press into general acceptance. My own statements were merely incidental and illustrative rather than positive. But I must now submit to Dr. Stone that his own figures, however true in fact, are misleading, and may be dangerous. He says I "re-assert erroneous statements" as to the resistance of the body, because I said that resistance is, from hand to hand, from 5,000 to 1,000 ohms, and he gives two instances of lower measurements which he has obtained. He speaks of "620 ohms instead of 5,000, per Sprague's minimum." But in this case he has introduced two fundamental differences. I was speaking of the "ordinary condition" of the body, such as may be expected in cases of accident. I submit that the cases will be very rare in which the contingent subjects of accidental contact with conductors will have taken much care to "overcome the transitory deception and dangerous skin insulation" by soaking the hands in salt water. In most cases the hands would be more apt to be dirty and oily, and the resistance approach or exceed my maximum rather than come down to this 620 ohms. In fact that was the very point of my remarks on this particular stage of the subject. I was contending that Professor Dolbear's figures were exaggerated by taking unlikely conditions, whereas the probable resistance would be increased by the small surfaces in contact, and I really cannot see in what way Dr. Stone's patient, with his carefully-prepared hands, affects my point.

But as a matter of scientific truth I object to measuring resistances in the manner adopted by Dr. Stone in this case, because I do not believe that it measures resistance at all. I consider that when we pass alternating E.M.F. into an electrolyte a very large part of the current shown is a delusion; that it does not pass through the electrolyte, but is a mere succession of charge and discharge of the surfaces, and that in measuring this as resistance on a bridge we are leaving out of account what is really a large shunt circuit, and the result is an apparent reduction of the resistance. I should attach no weight to any resistance measure unless it was based upon the steady and direct transmission of an electric current, testifying to the conducting capacity of the thing measured.

As to the physiological actions of electricity I should not think of comparing my knowledge with that of Dr. Stone, but I should like to ask him whether his suggestion as to possible coagulation of the blood is derived from any actual examination or is simply hypothetical. I am under the impression that the clotting of blood by the electric current is purely a secondary action of the products of electrolysis, and occurs only around one pole, while the bulk is unaffected. That is one of the actions which I indicated as likely to produce instant changes in the resistance if any large current were commenced.

As Dr. Stone seems to find something mysterious in my observation, which I thought simple enough, I may explain further that the effect of the setting up of difference of potential across living tissues must resemble the action in a series of condenser leaves, which we know move and rustle and are attracted together. So the different cells which form the tissue must, by the different conductivities of the liquids and the cells themselves, undergo an attraction which we recognise in the convulsive contraction of the muscles. It appears probable that such contractions, rapidly repeated may, at a certain limit, result in actual rupture. From what little we know of nervous action it is also probable that the nerves themselves may be rendered incapable of transmitting that energy upon which the continuance of life depends. I think that it is in this direction we must look, rather than to the effects of real electric currents measureable by Ohm's formulæ. Of course, adequate energy must enter the body; that is the meaning of the difference between the moderate shock of an induction coil and these fatal accidents. And here, of course, we are all at one. E.M.F., quantity, and time all enter into the problem, which, after all is rather how to avoid the risk of danger than the mode in which the body suffers injury.

This involves the now recognised fact that an alternating current is more dangerous than a continuous one (for the reason I have given) in which the same E.M.F. is operating; in fact, the continuous current gives one blow to the system, followed by some slight electrolytic action which may or may not be of consequence, while the other gives repeated rapid blows. One other consequence is that external induced charges are set up, and therefore a single contact is sufficient to produce effects from either conductor, while with continuous currents there must be a derived circuit set up through the body between two points.—Yours, &c., J. T. SPRAGUE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the discussion which followed Dr. Hopkinson's excellent paper upon Alternating Currents, recently read before the Society of Telegraph Engineers and Electricians, I was permitted by the kindness of the president, Professor W. G. Adams, to point out among other things certain effects upon the current generated by an alternating E.M.F. of capacity in the conductor, whether situated at a point or points, or distributed along the conductor, and I gave rules by which these effects may be in certain cases calculated.

The chief effect of such capacity is to increase the current in sections near the source of E.M.F. in comparison with those more remote.

Now, certain observations and experiments which I have made, lead me to the belief that the tissues of the human body through which an alternating current is sent exhibit very considerable capacity as well as mere inert resistance. This is a theory which explains, *inter alia*, much in connection with fatal and serious accidents. Its physiological explanation must be left to such men as Dr. W. H. Stone and Dr. W. H. Gaskell.

If it is true, it is not surprising that a test made to discover the resistance of the body upon the assumption that it is only a mass possessing inert resistance, by means of an alternating current machine, whose force has, perhaps, been determined upon measured inert resistance, should lead to small and erroneous results.

I have also pointed out that self-induction, which is almost always largely present in alternating machines, up to a certain point may act favourably in a circuit possessing capacity, which is not the case when mere resistance is in circuit.

If Dr. Stone, and Professor Dolbear, and the learned professors of Cooper's Hill College will apply the rules governing these actions to experiments made with the good instruments which they have at command, they will be doing a service to to science and humanity. As a preliminary test suppose they took the following series:—An alternating generator—a dynamometer—a man—a second dynamometer—a second man, and of these in this order made a closed circuit. Then, the alternations being set up, the first dynamometer will show more current-squared than the second.

Digitized by Google

The experimenters must not expect to arrive at a fixed value for the capacity, as if the tissues were a sheathed electric cable or a Leyden jar. The capacity will probably be found to be, like that of a voltametric series, variable with the charge.—Yours, &c.,

THOMAS H. BLAKESLEY.

Athenæum Club, Pall Mall.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I pointed out in the discussion on Dr. Stone's paper at "The Healtheries," the consideration of the physiological actions of the electric current is extremely difficult, for the reason that it is a question demanding an intimate knowledge of two great subjects—physiology and electricity—and no life is long enough, and no intellectual powers strong enough to compass it. Electrical engineers must necessarily be ignorant of the construction of the human or any animal body. The very utmost that anyone can have acquired will have been in his early students days, when he has taken it up as a subject, with others. Once he is launched on his career as a breadwinner, he can have little time to return to the subject, no matter how great may be his interest in it, all his leisure being taken up in keeping pace with the times. And, on the other side, the *rôle* of medical men is pretty well that of the busy bee.

It has always appeared to me, however, that the question of the resistance of the body *per se* was very much like the size of a piece of chalk; it varies with the dimensions, in this case, of the electrodes. Take, for instance, on the one hand, the case of a man immersed up to his chin in a metal bath containing hot acidulated water and grasping a large copper electrode connected with one end of the battery, while the bath itself is connected to the other. As half a dozen Smee cells are sufficient to give him a moderate shock if the circuit be interrupted, it is evident his resistance must be very small. Take, on the other hand, the case of a man whose hands are hard and dry, whose feet are encased in a thick pair of boots, and who stands on a dry slate ridge some distance above the ground and touches a wire carrying an electric light current with one hand.

I believe I should be correct in saying that under such conditions the resistance of the man would be so high that he would hardly feel any shock at all, though he might be near the positive terminal of the machine and large variations of current strength might be taking place within the electric light circuit.

The electrical conditions of danger were pointed out by Professor Ayrton, I believe, in his lecture at the London Institution some two years ago. They are two-fold.

1st. If a man interpose his body or a portion of his body between two points in an electric circuit between which great difference of potential exists, and if the conditions of the circuit made up of the generator, that portion of the wires between the generator and his body, together with that portion of his body which he has included in the circuit, be such that a current can pass of greater strength than his body in whole or in part can bear, then he receives an injury of a more or less serious description.

The meaning of this is clearly that if the resistance of that portion of his body which is in the electric circuit be, no matter from what cause, sufficiently low, a dangerous current will pass. As an instance of this I may mention the case of a man accidentally touching two brushes of a 40 light brush machine with *the back of one hand*.

The other condition is, if a man by touching a part of an electric light apparatus at a potential very much higher than that of the ground places himself as a derived circuit to the electric light circuit, then if the latter be not very well insulated, and if changes of great magnitude occur within the electric light circuit, the *extra current* will discharge, or a portion of it, through his body; and it is clear that here also the conditions of discharge depend on the resistance which his body, or so much of it as may be within the branch circuit, offers to the passage of the current.

It is evident that if he presented an infinite resistance he would receive no portion of the current. It is equally evident that if his body conducted infinitely well he would receive it all.

But the question is not affected, in my opinion, by how much of the current he receives. It is how great an excess has passed through him, or through one of his organs, above that which it can take without injury.

It has always appeared to me that Dr. Stone's measurements of his 7 feet of clinical clerk, and more recently the patient whose resistance he mentions as having measured from foot to foot—a case that can rarely occur in practice—are so much time wasted. The fact that certain men have been killed under certain conditions is proof positive that under those conditions they received more current than was good for them, and that their resistance must have been below a danger figure. What we wish to know is not the outside conditions, but the *inside* conditions.

If Dr. Stone's clinical clerk would submit to an exhaustive series of tests, to ascertain how much current he could stand in different parts of his body, it appears to me that whatever the result was it would be worth far more for practical purposes than thousands of measurements of that will o' the wisp—his absolute resistance.

I suggested to Dr. Stone, at the Healtheries, that before he would do much good he must plan out the human body into circuits, just as a telephone or an electric light engineer would plan out his circuits of lamps or telephones. He must be able to say, if a current enters the body at such a point and leaves at another point, it divides itself between such and such blood vessels, lymphatics, nerves, &c. The current passing in this artery acts inductively on the current passing in that vein; this vein being a conductor in motion sets up an electromotive force within itself, and so on. From which it will be deduced that when a certain current passes between two points, a certain fraction of that current, representing a certain current strength, passes through a certain very delicate organ. What is the result of the passage of that current through that organ? Does it infuse it? Does it heat it unduly? Does it distend it? and so on. It appears to me that this is the direction in which inquiry should go.

I understood Dr. Stone to say at the Healtheries that this could not be done. That certain facts were known—viz., that blood was the best conductor and bone the worst, and we must make the best of those facts. I take this to mean that it has never been tried, and that it is difficult. After the beautiful models and diagrams of the human body which I have seen, and which are public property, I will not believe it to be impossible; but I will say that, if the difficulty be shirked, electrical engineering science, still in its infancy as we are so constantly told, must be far in advance of the older science. Are not far more difficult problems faced daily? Take the reactions in a dynamo and a motor, for instance.

Now, as to the manner in which the current may cause injury. Given the fact that an injurious strength does pass—and here I wish to join issue most distinctly with Dr. Stone as to the question of lightning—I understand Dr. Stone to hold that the effects of lightning stroke, if I may use the term, are not the same as those produced by high tension electric lighting currents. To my mind the only difference is that which arises from the enormous tensions of the thunder cloud. It is very much the same as the difference between boiling water and molten iron.

All the effects that have been produced by lightning can be reproduced by electricity artificially generated, provided the same conditions be observed; and it appears to me that whenever we go away from the known laws of electricity, and try to explain apparent inconsistencies by some new law that we introduce for the purpose, we are raising up stumbling blocks in our own path, and with our own hands. It is our want of knowledge that makes the effects which we see apparently inconsistent with the laws which we know.

Perhaps there could hardly be a better instance of this than the one Mr. Sprague shows of the Holtz machine. Apparently Ohm's law does not govern the discharge, and yet, if all the conditions be taken note of, it is quite evident that it does.

Digitized by Google

There are several ways in which, in my opinion, an electric current may act injuriously upon a human body.

1. By shock.

2. We know that an electric current has the property, when passing through a nerve, of exciting that nerve to perform its natural function. Those who have given any attention to the matter know also that the strength of the current required to excite a nerve is very small indeed. In fact, one of the most marvellous points about the whole thing is the ridiculously weak currents which, when properly applied, do such great things.

We have, then, when a high tension current passes through the human body, first a violent excitation of all the nerves which lay in its path, followed very quickly by a violent contraction of the muscles that are controlled by the excited motor nerves. We know that this is so, because we have many recorded instances of men who have accidentally taken hold of wires carrying high tension currents being unable to release themselves, the muscles of their hands having contracted and clasped them on the wires.

What happens next? In the case of the alternating current we should have excitation and contraction followed by a momentary return to the normal state, and then re-excitation; and it is this violent succession of shocks which, as Mr. Sprague has pointed out, is so much to be feared.

The path of the current from hand to hand leads directly through the lungs, passing on its way some of the large vessels leading to the heart, and, most important of all, the pneumo-gastric nerve, which physiologists tell us may cause a stoppage of the heart's action should it receive a very sudden impulse.

I think we may fairly infer that, in many cases at least, particularly where both hands take part in transmitting the current, this pneumo-gastric nerve, receiving the sudden impulse delivered by the current, stops the heart's action. A second result that we must also expect from the passage of an electric current of high tension through a body of such high resistance as the human body would be that heat would be developed.

Apparently, however, this has not played a very important part in the injuries that have been effected by the current, with the exception of a scarring the skin of the hands, where the conductor has been grasped, and I think also in one instance of the face, where it had accidentally come into contact with the conductor. We have no record of any appearance due to heat in any other part of the body, or anything that could lead us to suppose that heat had played any part in the killing. On the other hand there are, I believe, authentic records of men and animals having been burnt to a cinder by a lightning stroke, showing that such might be possible under favourable conditions. The reason that we see no trace of heat except at what I may call the electrodes is, I believe, that once inside the body the current divides into so many branches, and as the heating effect varies with the square of the current, it rapidly diminishes.

But it must not be forgotten that however small the current in one of the branches into which it divides is, if that branch contain some delicate organ that cannot withstand even the small portion which falls to its share, serious injury and even death may result.

May it not happen, for instance, that one of the delicate portions of the lung may be scorched. How long would a man live under such conditions?

Another effect that I think we may look for from the action of a current of electricity upon the human body, is a quickening of those secretive actions upon which the well-being of the animal depends.

We know that each organ of the body receives the components it requires from that general carrier and purveyor, the blood, by means of a process of exudation through the membranes dividing the organs from the blood vessels; and we know also that the electric current has the property of causing liquids to pass through a membrane. Therefore it appears to me that these secretive actions may be quickened both by the stimulus given to the nerves, and by the direct action of the current itself. How is this action affected by the E.M.F. of the current? May it not be that there is a violent increase of these secretive actions, causing a derangement of other parts of the system? Knowing what a delicate apparatus the human body is, may it not be that in some such action as this the secret of the mischief is to be found?

It appears to me that this is eminently a field for experiment by the medical profession.

Another effect, it appears from Dr. Stone's letter, may be expected, viz., thrombosis, or coagulation of blood in the living vessels. I thought I understood Dr. Stone to say, at the Healtheries, that this thrombotic effect was an abnormal distention of the blood vessels. I am not clear whether these are the same, whether coagulation takes place first and distention afterwards.

I presume that the result is a stoppage of the circulation of the blood, causing, of course, cessation of life.

May not this distention be caused by the increased endosmotic action I have referred to? and may not there occur a more or less general mixture, fluids and secretions getting into places where they do injury, producing by their chemical action upon other fluids substances which may be highly injurious to the system?

Here, of course, we must remember that in all cases, so far as I am aware, what is done is done at once. I am not aware of any case of a man having lived for any time after receiving a stroke either from lightning or from an electric light current, except in those cases where they have felt no evil after effects whatever.

At the same time it certainly appears worth investigating whether men may not be injured, though not mortally, by the passage of too strong a current through them.

There is another effect which I think we have all of us overlooked, and that is the mechanical effect.

Professor Dolbear and Mr. Sprague have both rightly pointed out that time plays an important part in the question of whether a current does injury or not.

Electric light engineers know well that a conductor will stand a very much larger current for a short time than it will continuously, for the reason that heat takes a sensible time to develop. We find, therefore, in those cases where the E.M.F. is very large in proportion to the resistance of the body struck, and yet the quantity of current very small indeed, that mechanical effects of great magnitude are produced. A chimney stack will be hurled to the ground, large pieces have been taken out of the solid walls, heavy marble-topped tables hurled about like shuttlecocks, and all with very little indication of heat.

Remembering that the work done depends on $\frac{E^2}{R}$, there is evidently sufficient energy in a lightning flash to perform an immense amount of work, though the current developed may be small. May it not be, therefore, that some injury may be done mechanically to the internal organs, again causing death? I am exceedingly surprised that so little has been made of the opportunity that presented itself in the summer when the death occurred so unfortunately at the Healtheries. There were many peculiar points about this.

The tension of the machine was not the highest that is used, being only 1,250 volts; and, further, as far as I could understand from the report, the unfortunate young fellow did not receive the whole force of the machine. If I remember rightly, he touched one part with one hand, became giddy, or something akin to that, rolled over, and placed his other hand on another part. I believe it was distinctly stated that he did not touch the terminals. If this is correct it would point to something new—was the man's blood in a bad state? and what did the *post mortem* disclose?

I wrote twice to St. George's Hospital for information on the subject, but my letters were not even acknowledged. It is rather a striking commentary on the position taken up by Dr. Stone, and the reproof administered by him to the Royal Society for refusing his application for their assistance in his researches, that his own professional brethren should bar the way when an opportunity occurs of turning a terrible lesson to advantage.

I am sure the whole electrical profession will support me when I say that we are quite ready to do our part, so far as

Digitized by Google

we know how, to lessen the possibility of danger from the use of the powerful agent we handle; but, on the other hand, I think we should have the liberal aid of the medical profession in unravelling that portion which must necessarily lay beyond us.

The remedy for high tension currents is *not* to do without them, though it may be a grave question if they have not been introduced too early, but to know how to use them with safety. The advantages for extended lighting, and for transmission of power are so great that he who can show us how to use slight tension currents harmlessly, without dressing our workmen like "puss in boots," will be a public benefactor.

I think that the medical profession can do much in this direction if they will, and I think we shall all feel deeply obliged to those who, like Dr. Stone and Dr. Althous, lead the way.—Yours, &c.,

SYDNEY F. WALKER.

195, Severn-road, Cardiff, January 12, 1885.

HEATING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In common, doubtless, with many of your readers, I would thank Sir David Salomons for his letter and for the figures he gives. As a distinguished *dilettante* in the science of electricity, and as one who has spent much money and time upon it, anything he writes should command consideration; but I must confess that I do not quite see the *rationale* of his "warning."

I have drawn attention to the subject, feeling that it is one of sufficient importance at the present juncture, when great developments are taking place, to merit discussion, and to bring about if possible practical work. I have not done so without having good grounds for the belief, and indeed proof of the fact, that *for many purposes* heating by electricity can be carried out successfully and with a degree of convenience and comfort unattainable by any other known means.

It is not necessary for me to criticise Sir David Salomons' figures, for I certainly did not intend to convey any such suggestion as that "open coal fires or approved stoves" may be considered as things of the past, or that heating by electricity can be at present economically effected in positions or under conditions when such arrangements are readily available.

I hope, however, that Sir David Salomons' letter may be the precursor of many others, and that the subject may secure the attention and at least the *experimental* working out which I am bold enough to assert it deserves. I would wish to remark that when writing my letter of the 30th ult. I did not know of the existence of a very interesting patent, which I have just read, taken out by Mr. J. S. Williams in 1881 (No. 5233), which deals in a very comprehensive manner with this subject and is well worth perusal to those interested.—Yours, &c.,

JOHN S. SELLON.

The Hall, Sydenham, January 15, 1885.

SMALL MOTIVE POWER FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am glad to see in your issue of the 3rd inst. that Mr. Greenhill refers to the great want of a good motor for domestic lighting.

Those who, like ourselves, use the electric light for business purposes, take badly to gas in our homes. My reason for troubling you with this letter is to ask if you, or any of the readers of *The Electrician*, have had any experience with a new domestic motor made by Messrs Hathorn, Davey, and Co., engineers, Leeds, and said by them to require no more attention than a gas engine (and of course applicable where gas is either not available or very dear), to work at about 5lb. pressure, and to answer well for driving small dynamos?—Yours, &c.,

D.

[We saw this engine at the last meeting of the Royal Agricultural Society at Shrewsbury. It is said to have been considerably improved since. Mr. Davey, we believe, uses one to drive a dynamo at his own house. Perhaps he would give us some information on the subject.—ED. *E.*]

ELECTRO-MAGNETS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I gather from the ingeniously-worded letter in your last issue that "Volt-Ampere" is desirous of obtaining some practical rules for winding electro-magnets, and although I, too, look with silent awe upon those "double fiddle f's," yet I venture to present a few simple figures, both in the hope that they may be of some service to your correspondent and that they may call forth some more able demonstration.

In the first place, I will assume that the iron core is to be far from saturation, as is imperative in the construction of the field-magnets in dynamos.

In such a case the strength of the "field" may be expressed in ampere turns, and given a certain required strength in ampere turns, and a given difference of potential between the ends of the coil, the diameter of the wire may be calculated as follows:—

Let T = the ampere turns required
E = difference of potential in volts between the ends of the coil
n = number of turns on bobbin
r = resistance of bobbin in ohms
C = current in amperes
x = the length of a mean convolution in inches
d = diameter of wire in mils

We may take as a standard that a wire of 1 mil in diameter and of 96 per cent. the conductivity of pure copper 1·106 inchs measures 1 ohm. Then the resistance of any wire will be

$$\frac{\text{Length in inches}}{1{\cdot}106\,d^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 1.$$

From the conditions we have

$$T = \frac{E\,n}{r} = C\,n; \frac{n}{r} = \frac{T}{E}\text{constant} \quad . \quad . \quad . \quad 2.$$

$$r = \frac{x\,n}{1{\cdot}106\,d^2}, \; d = \sqrt{\frac{x\,n}{1{\cdot}106\,r}}.$$

By Equation (2) $\frac{n}{r} = \frac{T}{E}$,

$$\therefore d = \sqrt{\frac{x\,T}{1{\cdot}106\,E}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 3.$$

Having now found the diameter, it is obvious that if E is constant, as we are assuming it to be, T will also be constant, whatever n may be; for r varies with n and C varies inversely as r by Ohm's law. It is, however, necessary to make n sufficiently large as to avoid over-heating. This is readily calculated from the formula $d = 32\sqrt{C}$, whence $C = \left(\frac{d}{32}\right)^2$ being the maximum current which should be used on the stationary coils of dynamo machines to avoid wasteful heating. The wire should then be coiled on until $r = \frac{E}{\left(\frac{d}{32}\right)^2}$.

In conclusion, I would recommend "Volt-Ampere" to study Professor Silvanus Thompson's new book, "Dynamo Electric Machinery," which is probably the most valuable work for the practical electrician that has yet been written. Trusting that I am not encroaching too much on your valuable space, I am, yours, &c.,

G. C. FRICKER.

7, Charlwood-road, Putney, Jan. 10, 1885.

CONNECTIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you kindly tell me how the connections of a Gramme machine are made, as I am winding one and do not understand how the fields are connected; also what results ought I to get from 10lbs. of 16 B.W.G. on the fields, and 1½lb. No. 20 B.W.G. on the armature. I want to light 10 C.P. lamps.—Yours, &c.,

A. E. R.

PROFESSOR FORBES' PAPER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I regret to see two errors in my note of last week. The extraordinary formula for R is, of course, a misprint for

$$R = 2{\cdot}031 \times 10^{-6} \text{ ohm.}$$

The statement in the last sentence that a sheet of copper 1 c. × 8·9 metres would weigh about 1·5 ton per lineal foot should have been 530lb. This is somewhat amusing, considering that I was correcting a mistake which arose in a precisely similar way.—Yours, &c., W. H. SNELL.

BRAKES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: What would be the best form of "Prony," or friction-brake, to apply to the first motion shaft of a water-wheel, to ascertain the amount of power available, with a given fall and volume of water, for driving a dynamo machine?

The wheel makes fifteen revolutions a minute, and has teeth on internal segments of the periphery, into which a small pinion on the first motion shaft is geared. This shaft is about three and a half inches in diameter, and will make about 110 revolutions.

The object is to find out really what power can be depended on, so that the right size of dynamo may be put down.—Yours, &c., DANAE.

THE STOCK EXCHANGE INSTALLATION.

We herewith give diagrams of the arrangements of the electrical apparatus as used at the Stock Exchange. The space

FIG. 1.

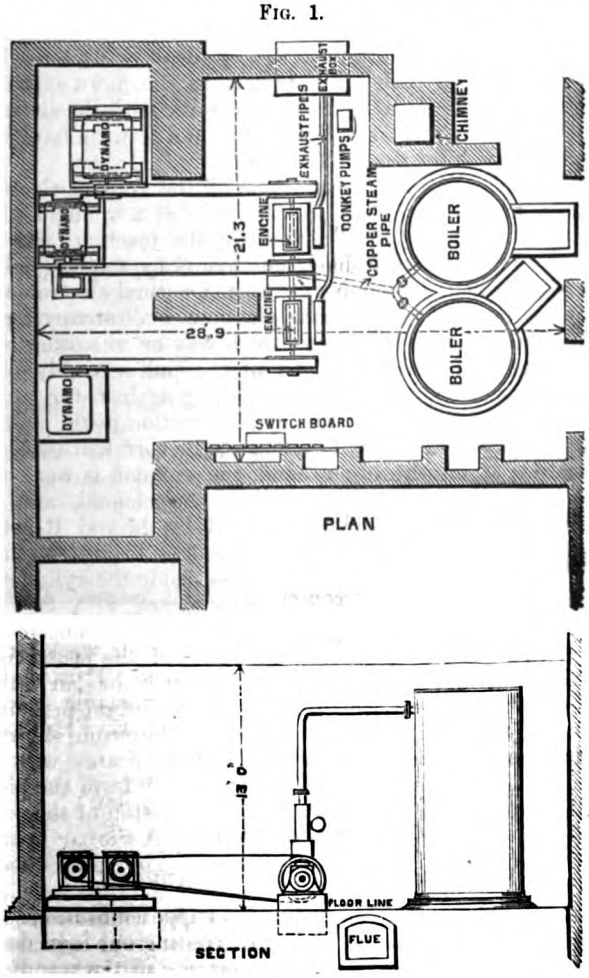

FIG. 2.

at the command of the contractors is very small, and, unless the dynamos had been run direct, the best use has been made of what is available. We have not before described the Willans engine, which has lately come into use for electric lighting purposes, and we are glad of this opportunity to illustrate it. As we stated last week, two engines are affixed, either of which can if necessary do the work at present required. Figs. 1 and 2 show a plan and elevation of the apparatus.

The engines, which were made by Messrs. Willans and Robinson, of Thames Ditton, are of the latest type of the Willans special compound engine for electric lighting, which differs in many respects from Mr. Willans' still better known marine engines. They are designed to indicate 60 horse-power each, at 600 revolutions per minute, and at this high speed they work with great silence and steadiness. To be seen to the best advantage they ought to be coupled directly to the dynamos, but owing to the great working speed of the latter this is impracticable, and they are driven by belts in what may be called the old-fashioned way. The high speed of the engines has, however, the advantage of rendering counter-shafting unnecessary, and to this extent space is saved, over and above the saving due to the small dimensions of the engines themselves, the base of each engine measuring only 3ft. 2in. by 2ft. The high-pressure cylinders are of 4½in. diameter, and the low-pressure 9in., the stroke being 6in.

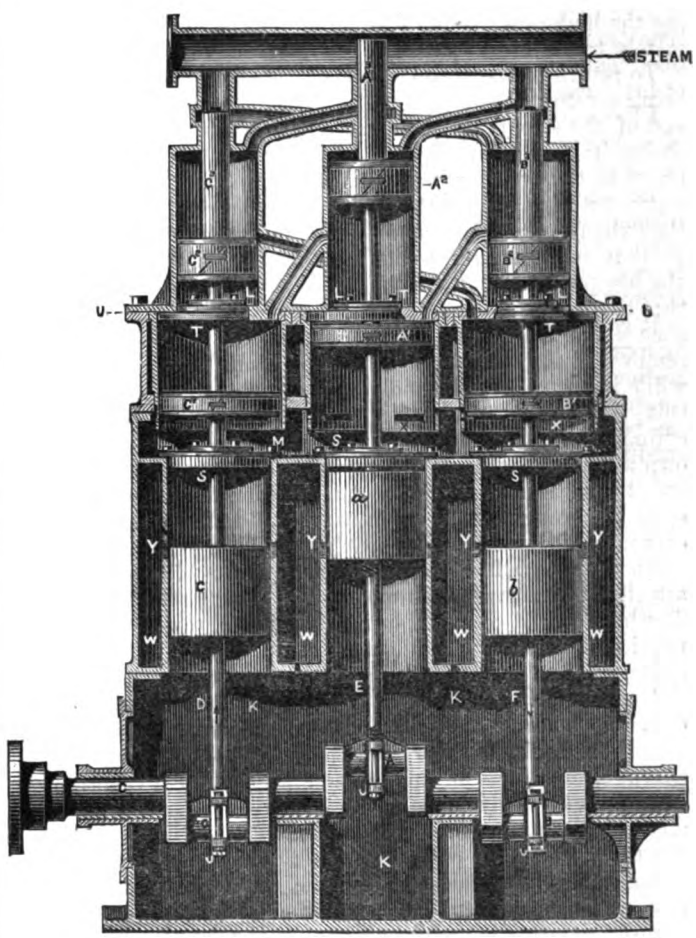

FIG. 3

Each of the pistons driving the three cranks A, B, C, consists of three parts, viz., (1) the low-pressure piston; (2) the high-pressure piston; (3) the cut-off rod or trunk, forming the valve for one of the high-pressure cylinders; *a*, *b*, *c* are the crossheads, taking the form of deep trunk pistons without rings, moving in guide cylinders. The latter are open to the crank chamber at the bottom, and are lubricated by the splash from the cranks. D, E, F are the connecting rods, of ample length; G, the crank shaft, running in phosphor-bronze bearings. The cranks and connecting rods work in the "crank chamber" K, containing oil, which is continually splashed up in spray over all the bearings, and up the inside of the hollow crosshead pistons to the steel pins upon which the upper ends of the connecting rods work. As there is constant down

Digitized by Google

thrust upon all working parts there is not much occasion for brasses *below* the crank pins, but to guard against accident brasses are fitted, but of reduced length. As they rarely, if ever, come into action, the setting up of the brasses is a matter which at most needs attention at very long intervals.

The three cranks being set at equal angles of 120 deg., the piston B^2 has just the proper lead of A^1 to enable it to supply A^1 with steam, with cut off at three-quarter stroke, and admission at the commencement of the stroke. This describes not only the relation of B^2 to A^1, but of A^2 to C^1 and of C^2 to B^1. Exactly similar relations exist between the cut-off rods B^3, A^3, C^3, and A^2, C^2, and B^2 respectively.

The cut-off rod B^3, which supplies steam to A^2, commences to uncover the ports leading to A^2, when the latter is at the top of its stroke. B^3 (on its way up) closes these ports again, when A^2 is at three-quarter stroke. At about the same time, A^2 begins to uncover the ports in the side of its own cylinder, which allow the steam, still acting upon A^2, to act also upon C^1, then at the top of its stroke. From this point, until A^2 reaches the bottom of its stroke, the steam expands on A^2 and C^1 together. A^2 then commences to rise, against a pressure which rapidly diminishes as C^1 continues its down stroke. When C^1 has travelled three-quarters of its stroke, A^2, rising, has covered up the port. Thenceforth the steam shut in above A^2 has no exit, and the clearances are so proportioned (including the high-pressure passages) that it is compressed approximately to the initial pressure.

To return to the steam above C^1. Communication with A^2 being severed, this continues to expand until, just before the end of the stroke, C^1 commences to uncover the oblong ports shown in the figure. By these openings a great part of the steam in the cylinder, and what is of great importance, *all the water*, are ejected into the space X, which communicates with the exhaust. It will be noticed that the position of the exhaust ports is much nearer to the lowest position of the piston in the low-pressure than it is in the high-pressure cylinders, and that the ports are consequently uncovered for a much shorter time. The reason of course is that, in the one case, the removal of the steam and water has alone to be considered, while in the other the time of opening has to be adjusted to suit the desired period of admission for the low-pressure cylinder. By the time C^1 has again closed the ports of its own automatic exhaust, the upward movement of A^2 has placed the steam still remaining above C^1 in communication with the space L, through which it can pass away to the exhaust (by an opening not shown) during nearly the whole of the upstroke.

The rods by which the high-pressure parts of the pistons are attached to the low-pressure parts pass through metallic glands, T, which consist only of spring rings like piston rings, and require no packing. Similar glands, S, separate the exhaust space, X, from the guide cylinders and the crank chamber.

Mention has been made of compression in the high pressure cylinders, where—chiefly owing to the considerable fraction of the stroke during which it takes place, and the character of the curve of compression in relation to that of expansion—it involves extremely little loss. Little or no compression is given in the low-pressure cylinders, and in the Willans engines of the marine type the compression in the high-pressure cylinders is alone amply sufficient to give the required "holding-down power," and to keep the connecting rod brasses always in thrust against the crank pins, and the crank-shaft always against the lower side of the main bearings. But at the very high speeds required in electric lighting work, other provision has to be made; and the special means adopted to absorb the momentum of the moving parts during the up-stroke are amongst the most characteristic features of the Willans engine. Besides its wastefulness when carried to excess, compression of steam in the cylinders is open to the objection that under varying conditions of working varying effects are produced. To avoid these, recourse has been had to a different fluid, which is always available and of which the character and pressure are invariable. Upon the upstroke of each piston work is put into the compression of *air*—to be given out again without appreciable loss upon the succeeding downstroke. The means by which this is effected, without adding any parts to the engine, is the subject of a separate patent. The cylinders in which the piston guides, *a*, *b*, *c*, work are closed at the upper end. At Y, Y, Y, are holes opening into the chamber W, the latter being in communication with the atmosphere, and by drain holes at the bottom with the crank chamber K. Towards the end of the downstroke the guide pistons uncover the holes, to ensure that the air-pressure in the cylinders shall be restored once in each revolution to that of the atmosphere. On the upstroke, as soon as the holes are covered, compression commences, and is carried to an extent governed by the amount of clearance provided (which can be varied within certain limits). On the next downstroke the air assists in driving the engine. Even if by the action of the governor, or by other means, the steam is wholly shut off while the engine continues to run, the effect of the "air-buffers" is not impaired; they are wholly independent of steam pressure, and the valve action of the engine may be designed without the smallest reference to questions of compression other than that in the high-pressure cylinders already referred to. It need not be said how great an advantage this is, or how largely it contributes to the remarkable economy achieved by these engines.

The most striking feature of the installation, from an electrical point of view, is the use of the Willans Electrical Governor, for regulating the speed of the engines, so that by varying the speed the electromotive force may be kept constant. How great progress is being made by Mr. Willans' invention is shown by the fact that already upwards of forty of these governors have been either applied or are about to be applied in installations. Even in the case of compound-wound machines it is becoming apparent that an electrical governor, which will keep the speed at least as uniform as the best centrifugal governor so long as uniformity is to be desired, and varies it if variation should be necessary, is preferable to a governor which can at best perform but one of these functions. But the electrical governor is seen to the best advantage when applied to shunt machines, which not only can scarcely be used without it (where great variations have to be dealt with), but which become, when used with it, as perfect as the more expensive compound machines. By arranging to work with the electrical governor, therefore, Messrs. Woodhouse and Rawson have been enabled to use shunt-wound machines.

In Fig. 4, which represents one of the Willans electrical governors in question, A A are the coils of a solenoid which form a shunt between the terminals of the machine, and B is an iron core suspended inside the solenoid by a spring, so adjusted that when a current due to the normal electromotive force is passing through the coils, the core shall occupy a position in which a small movement one way or the other shall not materially affect the strength of the pull upon it. The solenoid, it will be understood, is pulling against the spring, so that if from any cause, such as a reduction in the number of lamps, the current becomes stronger, the core will be drawn downwards; if, on the other hand, the current is weakened, the spring will overcome the pull of the solenoid, and will raise the core. The latter is connected by the rod R with a small double piston valve, P, which works inside the main hydraulic piston P^1, as the latter works inside the cylinder X. The hollow piston rods N and N^1—connected with P^1—pass through the ends of the cylinder X, and N^1 is connected by the rod F with the throttle valve, which is of the piston form, and works inside the casing T. The piston P^1 has an annular space round it, M, into which water or other fluid pressure is admitted by the pipe S. By a passage therefrom, shown in dotted lines, the annular space M communicates with the annular space between the two pistons which form the piston valve P. A passage, K, leads from the lower piston of the piston valve P to the upper end of the cylinder. A similar passage, K^1, leads from the upper piston of the piston valve P to the lower end of the cylinder.

In the position shown the current is supposed to be constant and the mechanism is at rest. If now the current is increased, the piston valve P is lowered by the lowering of the core B, and pressure is admitted to the top of the large piston P^1 by the passage K, which is uncovered by the lower piston of the piston valve, and at the same time the space below P^1 is opened to the exhaust by the passage K^1 and the hollow rod

Digitized by Google

N. This causes the piston P^1 to descend, and as it descends it closes the throttle valve by means of the rod F, and reduces the speed of the engine and dynamo, which in turn weakens the current and so stops the downward motion

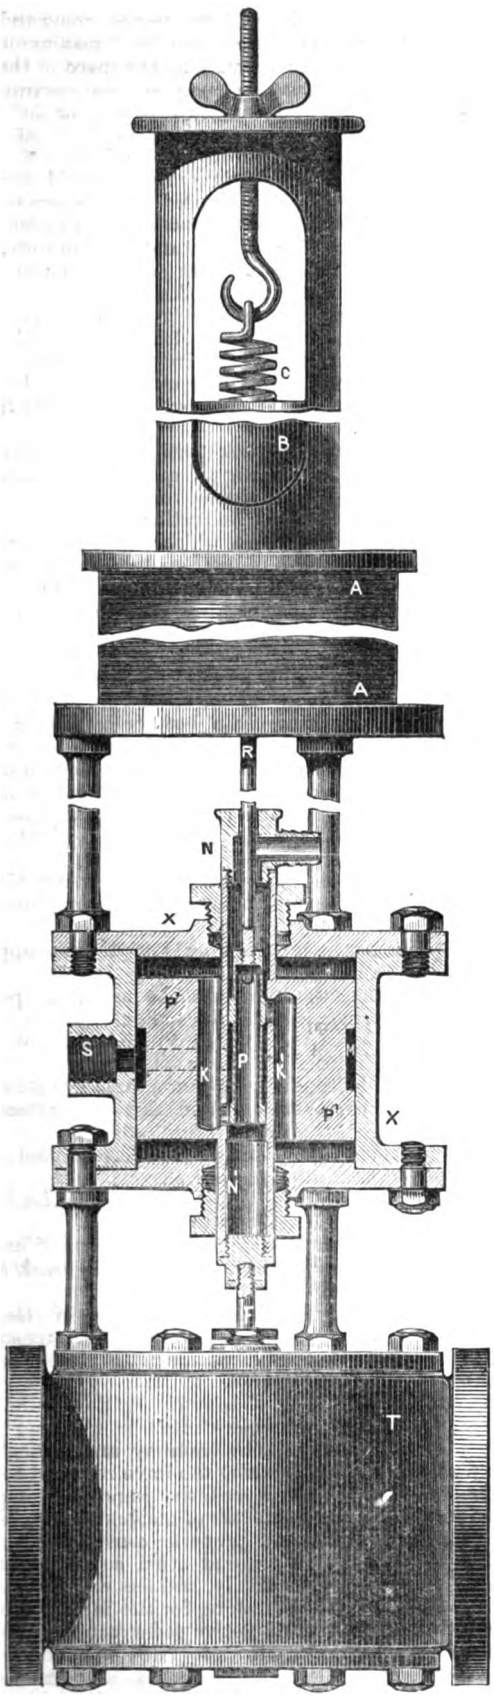

FIG. 4.

of the core B and the piston valve P. The latter coming to rest is immediately overtaken by P^1, and the passages K and K^1, being brought opposite to the now stationary piston valve, are closed, and the motion of P^1, owing to the inelastic fluid employed, is also immediately arrested. If the current is weakened the reverse action takes place. The sequence of the various actions described is extremely rapid, and consequently the piston P^1 follows so closely upon the piston valve P that the stopping or slowing of the latter produces an instant effect upon the motion of P^1, and "hunting" is entirely prevented. This overtaking action is in a measure analogous to the so-called "differential action" found in various steam steering gears, but it need not be said that the manner of its application is entirely different.

It is hardly necessary to point out that no solenoid of practicable dimensions could exert power enough to move the throttle valve direct, and that the system of using the pull of the core to bring another and greater power into action—in other words, the use of a relay—is essential to the efficient working of such an apparatus. But the substance of the invention, and that to which it owes its practical success, is the combination with the relay motor of interaction between the motor and the valve which starts it. To this alone is due the elimination of "hunting," and the absolutely steady action of the apparatus. The Willans governor assumes various forms to meet different requirements, but that which we have illustrated may be considered the standard form for actuating a throttle valve.

VIENNA EXHIBITION.

REPORT ON THE WOODHOUSE AND RAWSON LAMPS.

Professor Dr. Erasmus Kittler, Professor Dr. Antonio dos Santos Viegas, Dr. Josef Haubner, and Dr. E. Maiss, the jurors of the Vienna Exhibition, report as follows :—

In the first tabulated statement it will be seen that the lamps, even when run far below their normal candle-power, have an exeeedingly high efficiency. For instance, it will be seen that whereas a 20 candle-power lamp has an efficiency of about $2\frac{1}{2}$ watts when it is running at about 12 candle-power, it has an efficiency of 3·13 watts per candle-power, about equal to the Swan lamp; and when running at about 8 or 9 candle-power, an efficiency of about 3·77 watts per candle-power, equal to the Edison lamps. Of course, when the lamps are under run in this way the length of life should be very considerable.

The second statement gives the average efficiency of the total number of lamps tested, namely, 2·38 watts per candle-power, or 312 candles per horse-power :—

Normal C.P.	Observed C.P.	Current in amperes.	Difference of potential in volts.	Resistance hot in ohms.	Watts absorbed.	Watts per C.P.	No. of normal candles per electric H.P.
20	4·64	0·779	35·24	45·26	27·44	5·91	122
	6·85	0·838	37·65	44·95	31·54	4·60	160
	8·98	0·869	38·92	44·80	33·81	3·77	196
	10·85	0·905	40·35	44·59	36·51	3·37	219
	12·18	0·926	41·21	44·52	38·14	3·13	235
	15·58	0·966	42·83	44·34	41·38	2·66	277
	20·32	1·018	44·88	44·10	45·67	2·55	327
	26·27	1·071	46·92	43·79	50·27	1·91	385
	34·24	1·126	48·93	43·44	55·11	1·61	456
	45·81	1·193	51·25	42·95	61·16	1·34	515
Average of total number of lamps tested.							
20	20·78	10·72	46·26	43·71	49·38	2·38	312

These tests agree very well with the Wimbledon tests made by Mr. Preece upon the Woodhouse and Rawson lamps, which however, were lamps of a little later make. Messrs. Woodhouse and Rawson tell us that the lamps for the Vienna Exhibition were made over a year ago, and at the present time the lamps are much better, there having been a steady improvement since.

EVOLUTION OF THE ELECTRIC RAILWAY: Its Commercial and Scientific Aspect.*

BY DR. W. ADAMS, MEMBER OF THE ENGINEERS' CLUB OF ST. LOUIS.

(CONTINUED FROM PAGE 168.)

We must consider something besides the mere propulsion of a car. Electricity possesses innumerable novel and superior qualities or features which have never heretofore been presented to the railway constructor, although fully appreciated by railway economists. It behoves us to grasp and make the most of these. To be sure, some kind of operation may be for a while attained at maximum outlay, in a primitive impractical manner, but that which should be striven for is maximum economy as regards mechanical return, and such perfection in operation as will insure a minimum wear and tear. The application of electricity to railway propulsion means a complete revolution in railway construction and manipulation. In dealing with electricity as an agent of locomotion, it is unnecessary that we should adhere to those methods and processes which experience has demonstrated as essential to steam locomotion. On the contrary, having a totally different element to deal with, new problems are presented, and new principles involved. In handling the question of steam locomotion, Stephenson, after giving preference to the principle of traction over cables, concluded that it would be decidedly best to apply the power directly to each axle, or, better still, to each wheel of every car, and operate each car separately. Finding such an arrangement impossible, however, he next decided upon making each car at least its own locomotive. But this system also proving impracticable with steam, he, as a *dernier ressort*, adopted the "train system," with its ponderous locomotive. Had Stephenson and his followers found it as practicable with steam as we now find it with electricity to apply the power to direct each wheel, the long "train system" of locomotion would never have been instituted. One of the first requirements, therefore, of an electric railway system embodying the elements of permanency and commercial success, is the abolishment of the locomotive and its essential dead weight, which in turn does away with the "train system" and its numerous objectionable features. When a number of cars are coupled together their wear and tear and weight are necessarily greater. The impetus of a train being thus increased, it becomes more difficult to stop it, and the results of an accident are more disastrous both to life and property. The amount of air always carried between the cars of a train offers great resistance. All curves must be of higher degree than would otherwise be necessary, and a very much larger percentage of power is lost in making the curves than would be the case in a system applying the power to each wheel or axle. In the train system, if one car catches fire, or jumps the track, others are very likely to do the same, and thus again is the company's yearly expense greatly increased. The cars being individually heavier, and the necessity of providing for the weight of the aggregate number of cars massed together in the train system, increases the cost of the road-bed and all culverts and bridges. When we dispense with the locomotive and its attendant dead weight, we abolish the cost of the power consumed in propelling the same, and we greatly lessen the principal cause of wear and tear of the road-bed, culverts, bridges, &c., and, furthermore, we render possible the use of much lighter rails, and thus again further reduce both the first cost of construction, or the capital invested, and the cost of operation. Cars which are not being continually bumped together and wrenched to pieces by a heavy train may certainly be built lighter. In the locomotive train system the weight which must be provided to supply a proper amount of adhesion between the rails and the wheels is a *dead* weight, requiring as much power for its propulsion as is required by the remainder of the train; in fact, nineteen tons of dead weight must be hauled for every ton of passengers carried. Furthermore, this necessary dead weight is a fixed quantity, and does not vary with the actual paying load to be hauled. The adhesive power and its attendant dead weight to be propelled remain the same whether the accompanying cars are but one-tenth filled, or fully loaded, and railway statistics show that the average number of passengers carried by each train is but 70; whereas in a system having the tractive power distributed, whether the cars be run singly or in trains, the weight which gives the adhesive power is more nearly proportionate to the load to be carried; and the weight which contributes this adhesive power is not a dead weight, but one that the operators of the road receive pay for. As each passenger enters a car, an additional weight is supplied for the exertion of just as much extra traction between the rails and the wheels as is required to propel such an increase in the load.

Here, then, we have an expenditure directly proportionate to the demand, the height of economy being thus attained. A no less important indication in railway propulsion looks to the application of the power *directly* to the point where it is to expend itself. Be this never so desirable, however, such a thing is impossible with steam, but in every way practicable with electricity—indeed, electricity seems here to have found its grandest and most important application. Again, an all important indication for a successful electric railway may be said to lie in the fact that an electro-dynamic machine, when operating with greatest economy and safety, must, like a generator, run at a predetermined maximum speed. Hence, provision must be made for varying the speed of the car by some other means than by varying speed of the electric motor. Means must be provided for allowing the armature, or that portion of the electric motor which revolves at a high speed, to attain full headway independently before any load is placed upon it, and the latter should be applied gradually in order to avoid jerks. In addition to the economy and safety insured by this arrangement, we, in starting, allow advantage to be taken of the impetus of the motor in overcoming the inertia of a car, and, furthermore, we do not compel the motor to do its work rapidly, since it is a *sine quâ non* of an electric motor that it shall do its work slowly. Thus it will be possible for an electric car to attain maximum speed almost at the start, whereas from an eighth to a half mile is required for a steam engine to acquire its running speed. This one point alone renders electricity, when properly applied, particularly suitable for city surface and elevated roads, where frequent stops are necessary.

It must also be possible to vary the quantity of electricity running through the car, or, rather, of varying the quantity tapped from the main supply, without introducing useless resistance. There must, furthermore, exist at the central or generating station an automatic regulator, or equivalent arrangement, which will keep the supply of electricity in the mains always proportionate to the demand, and which shall regulate the amount of fuel consumed in the steam engine so that it, likewise, will be proportionate to the power or electric energy absorbed throughout the system.

But little, if anything, has been done towards developing the electric railway outside of what Dr. Siemens did in 1879, namely, the simple mounting of an electro-motor upon a car and connecting this up by means of a leather or chain belt, or by a train of cogs, with the car axle. Siemens at first built an electric locomotive, but we notice he soon abandoned this principle and began mounting his machines on each car and connecting these up with the axles by means of belts. Evidently, his discerning mind soon grasped the situation, and he began applying the power in a way better calculated to develop the superior advantages of electricity.

Edison and Field, however, have adhered to the locomotive principle and train system, as witness their exhibitons at Chicago and Louisville.

It certainly requires but little mechanical knowledge to appreciate the weak points about all these.

In the first place, either the cars must be mounted upon their axles rigidly without springs, or else the motor, which is mounted upon the car, and the axles with which the motor is geared, will move differently and will not always be in line.

Second, no form of belting will do for a practical commercial railroad—that is simply out of the question, as every engineer must concede at once.

Third, gearing between parts which move differently and are constantly getting out of line is also impractical.

But little has been done towards thorough insulation for the conductors, and in devising a practical moving contact.

Absolutely nothing has been suggested as a means of economic regulation, in every instance useless resistance being used, and the current wasted in useless heat.

To recapitulate:—Among the many advantages of electricity properly applied as a motor over steam for passenger transport, is the circumstance that no heavy machinery or fuel has to be carried about to set the train in motion. The carriages running singly may be built much lighter, thus reducing the power necessary to move them, reducing the noises made in running, greatly lessening the wear and tear of both tramway and rolling stock, reducing the first cost of cars, reducing the force required to brake the cars when going at a high speed, the impetus being less; reducing the force of concussion in case of accident, and hence the dangers and destruction to life and property consequent thereon; and, finally, permitting all bridges and other superstructures to be built more cheaply, more artistically, and less weighty than has heretofore been possible. Furthermore, for the same reason, and also because of the distribution of motive power attainable, greater speed may be acquired, sharper curves rounded with less than the usual wear, and steeper grades may be climbed. Experienced and trained engineers and firemen are not required to operate an electric railway. Any boy possessed of ordinary intelligence may be taught in half an hour to manage a car perfectly and cause it to perform all the work of a steam locomotive. This feature alone does away with a great source of expense now incurred by all steam railways, whether elevated or surface. The electric system also admits of the use of large, stationary, protected steam engines of the most economical type. The use of these as against small, ex-

* Paper read before the Society of Civil Engineers, America.

Digitized by Google

posed, portable ones, reduces immeasurably the wear and tear, as well as first cost, and also the amount of fuel necessary to develop a given amount of power; and if water power be utilised—as would very frequently be possible—the cost of operating such a railway system can be reduced to a comparative minimum. Further advantages are: Ability to get up speed quickly, which is particularly desirable for street and elevated roads; absence of noise; freedom from liability to many forms of accident now unavoidable, and from the annoyance of flying sparks, cinder, smoke, gases, grease, and the many other offensive and dangerous accompaniments of our steam railway system.

The time is now surely at hand for the economic and advantageous employment of electricity as a cleanly and cheap means of effecting rapid passenger transportation through densely populated cities and across the Continent. Jacobi, Davenport, Davidson, Little, Pinkus, and Page were in advance of the age in which they lived. No more rapid transit was demanded at that period of the world's history. The dynamo-electric machine which we have seen has rendered feasible the electric railway was not then in existence; hence they were obliged to apply electricity as a primary motor, an office which is filled far more economically by the steam engine, as was shown by their contemporaries in science, those versed in mathematics and thermo-dynamics. Now, however, the time is ripe for its introduction. We have reached the period of transition from the stage of practical demonstration to that of practical application. We now know how to apply electricity as a *secondary* motor; the dynamo-electric machine has been introduced as an industrial feature of our age; the project of electric railway transportation *now* has the sanction and enthusiastic support of the learned in the sciences of electricity, dynamics, and mathematics; and, lastly, we live in an age which demands more rapid transit. We think fast and live fast, and this naturally begets an almost insatiable desire and necessity to travel fast. Railroad managers are expected to provide the means of gratifying this desire with safety to passengers and without detriment to their earnings, if possible; but at all hazards to put trains through according to the latest and fastest schedule. For a number of years the regular time between New York and Chicago has been 36 hours, or a speed of 25 miles an hour, including stops. This is not what might be called slow; but the impatient public is more than ever impressed with the idea that "time is money," and that something better than this should be accomplished, in view of the improvements in rails, road-beds, and rolling-stock. Managers, in order to meet this demand, are put to a terrible strain. They must provide the ways and means, head off competition, take the responsibilities and risks of accidents, and, what is more important than all, they must make the traffic pay.

This last requisite, in the face of rival fluctuating rates, the enormous dead weight of locomotive and tender, of sleeping and drawing room cars, and the excessive wear and tear of track, superstructure and rolling-stock, from the increased weight necessary to effect such rapid transit *with the steam system*, is not an easy thing to respond to. Managers, master mechanics and car builders have for a long time regarded the rapidly increasing weight of trains as a growing evil that should be checked to prevent expenses from swallowing up earnings in passenger traffic. Fast running under existing conditions is extremely hazardous as well as expensive, and this simply because of the enormous weight given to railway trains. The tractive force of twenty to sixty tons exerted by the driving-wheels of a locomotive on an eighth of an inch of rail soon tears a tramway to pieces. These conditions are practically reversed in the writer's electric railway system. It might almost be said that here the lighter the rolling stock the greater the possibilities as to speed. Calculations based on the numerous points of advantage herein specified show that an electric railway may be operated at an average speed of sixty miles an hour for one-third the cost of operating by steam at the same speed.

If the train system must be discarded as least calculated to develop the advantageous qualities of electricity as applied to railway propulsion, then a practical method of applying this power upon each car must be devised, and this has by many eminent engineers been found to be no easy matter, but, on the contrary, a most complex question, fraught with many difficulties. The armature of the electric motor must run at a high speed, and its power must be transmitted to the wheels of the car by a *positive* gearing. All forms of belting were at first sight seen to be entirely impracticable; while gear wheels between parts moving differently were not to be considered. Everything electrical and mechanical, including that fundamental law of mechanics which directs that power shall in every instance be applied as *directly* as possible, seemed to point toward a direct application to the wheels. But how was this to be accomplished? As we have before noted, the armature or revolving part of the electric motor must move at a very high speed, entirely too high for the speed of a car wheel. And, furthermore, it is very evident that it was impossible to construct an "armature" upon the modern dynamo principle which should also serve as a car wheel—such a dual function was out of the question. And yet it was imperative that the principle of the motor should be that of the most efficient type of the modern dynamo.

However carefully the reader may examine into our simple solution of this question, no adequate conception can be formed of the amount of thought and work which has been bestowed upon it.

We have succeeded in applying the power directly to every wheel, to the point of traction, where the power is absorbed, the work done, and yet our wheel is neither an "armature" nor a "field" of a dynamo. It is both combined! In other words, every wheel is a dynamo in itself. Each wheel is *animated*, having power within itself. Hence every wheel becomes a veritable locomotive.

(TO BE CONTINUED.)

LEGAL.

Important Case as to the Issue of Debentures.

EDWARDS *v.* THE DUPLEX ELECTRIC LIGHT COMPANY.

In the Chancery Division of the High Court of Justice, on the 14th inst. (before Vice-Chancellor Bacon), an action was brought by Mr. John Edwards, a tool manufacturer, of Waterloo Bridge-road, as the holder of certain debentures in the defendant company, to enforce the due carrying out of the debenture deed, dated the 17th May, 1883, made between the defendant company on the one part and the defendants John Mallard and Stephen H. Emmens on the other part, under which the debentures were issued; and for all necessary inquiries to be made, and a receiver to be appointed.

Mr. Marten, Q.C., and Mr. Asheton Cross, instructed by Mr. J. N Jonas, appeared for the plaintiff; Mr. Millar, Q.C., assisted by a junior, instructed by Messrs. Munns and Longdon, for the liquidator of the company; and Mr. Livett, instructed by Mr. F. T. Rushton, for the trustees of the debenture deed.

It appeared that the Duplex Electric Light Company was floated in May, 1882, for the purpose of taking up Mr. S. H. Emmens' patent. After the company had been started a year, in May, 1883, owing to the company being pressed by various creditors, Mr. Emmens, who had been appointed the manager of the company, made a proposal to the directors that they should issue debentures on the whole capital and stock of the company for £20,000, in 2,000 shares of £10 each; and a resolution embodying that proposal was accordingly passed at a Board meeting held on the 8th of May, 1883. On the 6th of January, 1883, a petition was presented for the winding-up of the company by the British Trading Company, who alleged that they were creditors, but Mr. Jonas intervened on behalf of Mr. Elmore, of the Elmore Electrical Works Company, on the ground that the petitioning company was also one of Mr. Emmens's promotion, and that therefore the petition was collusive. The winding-up order was made on the 14th July, 1883, by Mr. Justice Pearson, and Mr. Wm. Waddell appointed official liquidator and receiver on behalf of Mr. Elmore and the other creditors. Upon Mr. Waddell absconding Mr. Samuel Lovelock was appointed in his place, and now opposed the enforcement of the deed on the following grounds: 1st That there was no proper quorum of directors present at the Board meeting at which the resolution in question was passed; and 2nd that the debenture deed was not executed as a Bill of Sale in conformity with the Act of 1882, inasmuch as the consideration was not rightly stated.

Mr. MARTEN, Q.C., on behalf of the plaintiff, contended that at the Board meeting on the 8th of May, 1883, there was a proper quorum of directors present, the number of directors required to form a quorum being three, and at that particular meeting there were present Captain G. F. Hunt, E. B. Ilidge, C. Drake, and Mr. Emmens, as shown by the agenda and minute books of the company, in the former of which a resolution was entered to the effect that the debentures were approved and signed. The learned counsel then went on to argue that the Bills of Sale Act did not apply to the liquidation of a company, and called the attention of the Court to the 17th section of the Act, which he said specially provided that the Act was not to apply to the debentures of a company. In the course of his argument the learned counsel quoted several cases, amongst others that of the Romford Canal Company, 24 C. W., p. 85, and Webbe *v.* the Commissioners of Herne Bay, 5 Law Reports, 5 Q. B.

Mr. LIVETT, on behalf of the trustees of the debenture deed, adopted the same argument as his learned friend Mr. Marten had used.

Mr. MILLAR, Q.C., for the defence, urged the debentures were bad because they were issued without a quorum of directors, and said that he should call witnesses to prove that three directors were not present at the meeting, and that Mr. Emmens was not a director of the company at all. The debentures were issued to the shareholders on the following terms—that for a £10 debenture credit should be given to them for the £5 paid on their shares, and that they should have a £10 debenture by paying another £5. The whole proceeding was utterly irregular. It was only proposed to issue debentures to the shareholders, and the company was to take in payment fully paid up shares, and the company was to be made to bank its own capital. The minutes of the proceedings at the Board meeting had been prepared since, and were grossly inaccurate. In the agenda book on one side was written "Proposal as to issue of first mortgage debentures," and on the other side "Approved, subject to counsel's opinion." So that the resolution was only a conditional one, subject to

Digitized by Google

counsel's opinion, and he would challenge his friend Mr. Marten to show that counsel's opinion had been obtained in favour of the scheme. The learned counsel then read several letters which had passed between Mr. Emmens and Mr. Rushton (the company's solicitor) on the subject, one of which states that counsel had given an opinion opposed to the scheme.

The Court here rose for the day, and the further hearing of the case was adjourned.

HOLLINGS *v.* THE CONSOLIDATED TELEPHONE COMPANY.

This was a claim for £79 11s. 4d., balance of account for the supply of telephone generators made by the plaintiff, and supplied to the defendant company. Mr. Atkinson appeared for the plaintiff, and Mr. Metcalfe for the defendants.

Plaintiff said he was a machinist, carrying on business in Kerby-street, Hatton-garden, and he had for some years manufactured an instrument called magnetic generators for the company, in quantities of 1,000 at each order. When the generators were delivered they had to be accompanied with bell-handles and frames, and special castings, screws, &c., were required for this work. His first transaction with the company was in 1881, when he received a verbal order for 1,000 castings, which were delivered and paid for. A similar order was executed in 1882, and in October, 1883, he got an order for 40 gross of poles, which were all delivered and paid for. In May, 1883, he received a letter from the company ordering 1,000 generators, with bell-handles and frames, which were all delivered in November of that year. In October, however, he got a verbal order to repeat the order of the preceding May for the 1,000 generators; but whilst he was executing the latter a pattern was sent for some trifling alteration in the manufacture. Half a-dozen samples of the new pattern were made and submitted to the then manager of the company (Mr. Rose), who was quite satisfied; and on 22nd January, 1884, Mr. Rose gave him a verbal order for 1,000 of these generators, for the manufacture of which he had been obliged to make new tools. In February he delivered 200, which were accepted and paid for by the company, and down to the following April 138 more were also sent in. On 1st April, however, he received a letter to the effect that Mr. Rose had severed his connection with the company, and on receipt of that circular he saw Mr. Curtoys, the secretary, and asked who he (plaintiff) was to look to for future business. Mr. Curtoys said it would not make the slightest difference, that he was quite satisfied with the work which had been done, and that plaintiff would be perfectly justified in proceeding with the contract he had in hand. He sent in his account up to March 29, and added a foot note stating that the goods then delivered did not include those in course of manufacture. According to instructions he made 300 more, and had them in hand. Just before Easter he again saw Mr. Curtoys, who asked him how many he had in hand, and he said 300 partly made, and asked for his account to be laid before the company, so that he might get a cheque. Mr. Curtoys then said he did not know that the company owed plaintiff anything, but the clerk brought the account to February, which amounted to about £90. When he told the secretary he had 300 in hand, Mr. Curtoys said he could not receive them then, as they were taking stock, and they had only a few men at work. In April he received a letter to the effect that no goods were to be delivered without a written order from the company, but all the generators supplied were by the verbal order of the late manager, Mr. Rose.

Mr. METCALFE contended that these orders were irregular from the start, and it was found necessary that orders could not be given in that way.

The learned JUDGE pointed out that some of the goods had been received before that date, and it did not matter whether the secretary knew of it or not.

A JUROR remarked that the company ought to have seen their instructions carried out.

Mr. METCALFE: If the jury have made up their minds——

The JUDGE: Did the company make a new rule with regard to an order which had been partly executed?

Mr. Metcalfe resumed his seat, whereupon

The JUDGE, amidst some amusement, remarked that the counsel for the defence had "gracefully retired," and by his direction the jury gave a verdict for the amount claimed—£79 11s. 4d.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.

Report of the Directors, to be presented at the 12th ordinary general meeting of the Company:—

The Directors submit their report and the accounts of the Company for the year ended 30th September, 1884. The total earnings amount to £106,174 8s. 4d., a decrease of £6,532 2s. 8d. compared with last year, caused by the interruption of the Brazilian Submarine Company's cable. The working expenses for the year, exclusive of renewals of cable, amount to £61,871 5s. 2d., as against £61,127 19s. 11d., an increase of £743 5s. 3d. These expenses include £1,129 14s. 6d. for depreciation of steamship "Viking," an item which did not enter into last year's accounts. Including the amount brought forward from last year, the balance to the credit of the revenue account is £18,757 8s. 9d., from which, for the reasons given hereafter, the Directors regret they cannot recommend the payment of a dividend. In consequence of the interruption of the Brazilian Submarine Telegraph Company's cable between St. Vincent and Pernambuco, referred to in the last report, and of a second interruption of the same section from the 2nd to 28th March, 1884, the revenue of the Company derived from international messages was almost entirely wanting for no less a period than 101 days The duplication of the cables of the Brazilian Submarine Telegraph Company, which has since been effected, will in all probability prevent the recurrence of such a serious loss to the revenue of the Company. The Company has had to replace by sheathed cable during last year 382 miles of the old unsuitable type of cable; the amount thus expended, £36,622 12s. 1d., has been charged to the renewal fund. On the other hand, the Directors have credited the same fund with £15,000, part balance from revenue account, absorbing the amount which otherwise would have been available for dividend. Attention has been repeatedly drawn to the reasons which necessitate the employment of two steamers, and the gradual removal of the old strand type of cable. The greater portion of this type has now been replaced by sheathed cable, and such lengths as still remain will be dealt with in the same manner. Until the Company's system consists of sheathed cable from end to end, the Directors must provide against interruptions in the strand cable, which should never have been laid in the first instance, and the interruptions in which have been the source of constant difficulty. The mileage of the strand type has been reduced from 2,500 to 450 miles, and the Directors consequently hope to make arrangements in reference to the repairing ships which will shortly reduce the heavy outlay now necessary. The Company would have suffered to a much more considerable extent from competition had they not been in a position to effect speedy repairs with these vessels. Notwithstanding the reduction in tariff made by the Company last year, the revenue shows a very satisfactory growth, and the Board think it right to state that the revenue for the first quarter of the current financial year not only shows that the loss of last year has been recouped, but that the traffic is in excess of any previous year. The general position of the Company, financially and otherwise, shows decided improvement. The retiring Directors are Mr. C. W. Earle and Mr. H. Weaver, who offer themselves for re-election. The auditor, Mr. Weise, retires, and is eligible for re-election.

NOTES.

HELIGOLAND.—The cable between Neuwerk and Heligoland is interrupted.

THE TELEPHONE IN AMERICA.—Boston and New York are now telephonically connected.

WORKS LIGHTING.—We learn that Messrs. Sharp, Stewart, and Company, of Manchester, have decided to light their works by electricity.

HEATON MERSEY.—The postal authorities have taken steps to ascertain the number of telegrams sent to this district, in order to decide whether or no a telegraph line shall be erected.

EARTHQUAKES AND EARTH CURRENTS.—We are a little surprised to learn that nothing exceptional has been noticed with regard to earth currents during the recent earthquakes in Spain.

COLLIERY WORK.—The Tirpentwys Colliery owners have adopted the electric light for the external part of their colliery. It is found to work very satisfactorily, and other companies contemplate its adoption.

ELECTRIC LIGHT AT AOSTA.—On the 1st inst., the lighting of Aosta by Ceruta lamps and Thury dynamos, under Professor Farinet and the engineers Taddei, Carrone, and Garnier, was inaugurated amid great popular rejoicing.

CURRENT METER.—The Gerboz measurer of electric current depends for its action on the gauging of a quantity of water, which only flows while the current passes. The latter actuates a number of valves by means of an electro-magnet.

CROOKHAVEN.—The laying of the cable connecting Lloyd's Signal Station on the Fastnet Rock with the mainland has been successfully accomplished, and connection is being made between the cable and the Postal Telegraph Office at Crookhaven.

INTERNATIONAL EXHIBITION AT THE ALEXANDRA PALACE.—The administration have, it is reported, concluded an agreement with the Gülcher Electric Light Company for illuminating the palace and grounds with the largest combined installation in England.

THEATRE LIGHTING.—It is reported that the Court Theatre, Monaco, is to be entirely illuminated by the electric light, the conductors consisting of six underground cables, and that the chief mechanician has patented a form of incandescent lamp for giving novel effects of coloured light.

FLIRTATION BY WIRE.—It is said that the loss of time due to trivial communications between the lady clerks and the subscribers at one of the principal New York telephone offices became so serious, that the manager had all the shunt circuits put in communication with his office, with the desired result.

AN ELECTRIC CHRISTMAS TREE AT ST. PETERSBURG.—This year when the Empress of Russia's cuirassier regiment and the Emperor's special escort had their annual Christmas tree at the St. Petersburg manège, in the presence of their Majesties, the tree was lighted partly by small Edison electric lamps.

THE JABLOCHKOFF ELECTRIC LIGHT COMPANY V. HOWARD AND WYNDHAM.—The reclaimers on Wednesday withdrew their note in this case, as an extra-judicial arrangement had been arrived at between the parties, with a view to the renewal of the electric light installation under improved conditions.

THE TELEPHONE AT INVERNESS.—The National Telephone Company has opened an exchange in Union-street, Inverness, connections having been made with about fifty of the principal business houses in town and suburbs, while it is expected that connections will shortly be made with the neighbouring towns, such as Nairn and Dingwall.

TELEPHONE BETWEEN FRANKFORT AND MANNHEIM.—It is reported that the local authorities of Neu-Isenberg, Spendlingen, and Langen oppose the passage over their territory of the telephone wires for connecting Frankfort and Mannheim, and that the whole question as to this "right of way" is now before the German law courts.

SKATING BY ELECTRIC LIGHT.—Advices from Brussels say that there has been skating on the lake in the Bois de la Cambre for several days, and that the lake has been temporarily lighted by electricity at the expense of the Ixelles Steam Tramway Company, which ran five cars, drawn by two engines, every ten minutes up to midnight.

ELECTRICAL EXHIBITION, PARIS.—The Electrical Exhibition, organised by the Société Internationale des Electriciens, with the co-operation of Admiral Mouchez, at the Paris Observatory, is announced to open on the 15th March. Applications for space will be received up to 10th February, at the company's head-quarters, 3, Rue Séguier, Paris.

THE TELEPHONE IN AMERICA.—The United States Telephone Company is preparing to establish lines in New Haven and elsewhere throughout Connecticut in opposition to the Southern New England Telephone Company, which at present exercises a virtual monopoly of the business. The United system is claimed to be superior to that of the Southern.

JOINING COTTON BELTING.—The jumping of cotton belts, imperfectly joined, has been a cause of difficulty in driving dynamos. In reply to a correspondent, the *Timber Trades Journal* advises as follows on this subject:—To prevent a cotton belt from jumping it should be made with a taper joint. This can be done by cutting off plies at different lengths, letting one end overlap the other, and lacing in the usual way.

TELEGRAPH POSTS AT BUCKINGHAM.—At the last monthly meeting of the Buckingham Town Council, attention was called to the unsatisfactory positions in which some of the new telegraph posts had been placed. It was, however, stated that the posts had only been placed temporarily as yet, and that, before they were loaded with the full complement of wires, they would be put in proper position. There were ten on the London road which would have to be shifted.

ELECTRIC LIGHT IN MILLS.—Owing to the high speed at which the various machines are run at Messrs. Ermen and Roby's Mill, Patricroft, near Manchester, the greatest difficulty was experienced to keep anything like a steady light with gas, in fact it was not at all uncommon for the gas jets to be blown out. The Simplex Electric Light and Plant Company has now installed some Müller's incandescent lamps maintained by a shunt-wound dynamo, driven by a small horizontal engine. Among other works that this company has in hand is the lighting of Messrs. J. Robertshaw and Son's mills, near Bradford, and Messrs. T. Ormerod and Co.'s mill, Haslingden.

OVERHEAD WIRES.—At a recent meeting of the Chelsea Vestry, the Committee of Works considered a letter from the St. George's, Hanover-square, Vestry, enclosing a resolution to the effect that they regretted the Government had not seen their way to legislate on the subject. The chairman said Sir Charles Dilke had told him there would be a select committee appointed to inquire into the subject, and the question was adjourned.—The Lewisham Board of Works concurs in the views of St. George's (Hanover-square) Vestry, that the control of overhead wires should be under some adequate

Digitized by Google

local authority, and that in the metropolis such authority should be the vestries and district boards.

THE TELEPHONE IN PARIS.—The following classification of the subscribers to the Société Générale des Telephones in Paris was given by the *The Times'* correspondent last Saturday :—Bankers, 234 in 1884, and, owing to the closing of 14 unsuccesful banks, 222 in 1885; brokers, 102; newspapers, 71; printers, 65; cab proprietors, 60; booksellers, 56; engineers, 50; builders, 41; stockbrokers, 37; publicists, 30; clubs, 27; architects, 27; restaurants, 26; railway companies, 26; hatters, 22; insurance companies, 21; barristers and solicitors, 21; hotels, 21; cafés, 21; theatres, 15; dressmakers, 14; Government offices, 9; physicians, 6; Chinese shops, 3; and embassys, 1, namely, that of Russia. The subscribers are charged at the rate of 600f. (£24) per annum.

LAUNCH OF A CABLE STEAMER.—A launch took place at the yard of Messrs. R. Napier and Sons, Govan, on Monday, the 19th inst., of a steamship designed for laying down, picking up and repairing submarine cables for the Eastern Telegraph Company. As the vessel slid into the river she was named the "Electra" by Mrs. R. W. Renwick, of Glasgow. The ss. "Electra" might be called a sister of the ss. "Magneta," which was launched exactly a month ago, on the 19th of December, for the Eastern Extension, Australasia, and China Telegraph Company, being of similar dimensions. The ship is 230ft. in length by 32ft. in breadth, and has 24ft. depth of hold. She is built of steel, and was designed by Mr. Joseph Birnie, of London. We hope to illustrate and fully describe this vessel in an early number.

RIVER PLATE TELEPHONE COMPANY.—The shareholders of the River Plate Telephone Company and the Consolidated Telephone Company will doubtless be glad to hear that the manager of the former company, while on a short visit to England on business matters, reports that it is doing very well indeed, that all the leading people of Buenos Ayres are on the exchange, and that the Government uses the Gower-Bell instrument in preference to the Bell and Blake. The latest returns show 1,300 paying subscribers in Buenos Ayres, and a large increase in Monte Video since the company reduced its rates for subscribers to meet the opposition tactics; and no doubt this increase will be maintained, as the Gower-Bell instrument is fully appreciated in the Argentine Republic, and it was solely the higher rates which drove the subscribers away.

CABLE TO THE WEST COAST OF AFRICA.—In view of the desirability of providing a means of communication by telegraph between Great Britain and the British Settlements and Protectorates on the West Coast of Africa, the Government is prepared to recommend Parliament to grant a subsidy to a contractor for laying, maintaining, and working a submarine telegraph cable from St. Vincent (Cape Verde Islands) to Bathurst, Sierra Leone, Accra, and thence to a place along the coast not further east than Victoria Settlement in Ambas Bay, either direct or touching *en route* at Lagos, or touching *en route* both at Lagos and at a point on the Niger. The last day for the reception of tenders is Thursday, the 12th prox.; they must be enclosed in sealed covers, marked "Tender for West African Cable," must be addressed to the Secretary, General Post Office, E.C., and be delivered by twelve o'clock noon on that day. The conditions will be found in our advertising columns.

"THE EVENING SUN."—This is the title of a lecture given by Mr. Eric S. Bruce, M.A., M.S.A., at the Pump Room, Tunbridge Wells, on the 16th inst., and repeated at the Young Men's Hall the following day. The lecturer started from Franklin's experiments, on the locality of which the Philadelphia Electrical Exhibition was afterwards held. He said that electricity was "not matter, but a molecular condition of matter—a species of energy—a mode of motion," and that, to obtain cheaper light from electricity, we must look for improvements in the dynamo and greater efficiency in incandescent lamps. Already the Woodhouse and Rawson lamp required only $2\frac{1}{2}$ watts instead of the usual $3\frac{1}{2}$, thus admitting of 30 per cent. more lamps in the same circuit. The lecture was illustrated by views projected on the screen, and also by many interesting experiments, including the blowing of an incandescent lamp from a glass rod, and the fitting in of its carbon filament.

NEW GUINEA NATIVES AND ELECTRIC LIGHT.—A correspondent who was at the annexation proceedings, writing to the *Register*, says:—"The 'Nelson' was lying at anchor some miles from the village; but, by the aid of her electric light, the huts on shore could be plainly distinguished. Then for the amusement of the natives the siren or fog horn of the 'Nelson' was sounded. The effect was ludicrous in the extreme, the instrument alternately groaning and barking and making the most extraordinary noises. In some instances I was informed the natives thought the two electric lights to be the eyes of some great monster; and, when they heard the sounds of the siren, they immediately concluded that it was the voice of the monster, and numbers of them ran away and hid in the bush in terror. While the illumination was proceeding, the moon rose through a light bank of clouds over the hills, and the electric light and firing off of rockets was one of the prettiest sights that anybody could wish to see."

CANADIAN TELEGRAPHS.—The telegraph system in Canada is in the hands of public companies chartered by Act of Parliament, the largest and most important of these being the Great North-Western Company of Canada, which is formed by the union of the old Montreal and Dominion Companies; and this company has 31,673 miles of wire in operation, with 17,042 poles. The rate in Canada for a message of ten words, address and signature not counted, is 25c. (1s.), and 1c. for each additional word, a message being sent at this rate for a distance of 1,300 miles. The price for special newspaper reports is as cheap as 25c. (1s.) per 100 words; and the actual number of words of newspaper reports received at one city (Toronto), and furnished in one year, is 10,807,668. There are also the Canadian Mutual Telegraphs, while the Government owns some telegraph wires. The telephone system is in very active operation in all the towns of Canada, the city of Ottawa alone, with a population of about 28,000, having about 100 miles of wire in operation.

SOCIETY OF ARTS PRIZES AT THE INVENTORIES.—Among the special prizes (independent of the jury awards) announced by the Society of Arts to be given by it at the forthcoming Inventions Exhibition, are gold medals value £20 each, under the Howard trust, one for the best exhibit in Group 4, Prime Movers, Class 26—steam engines and boilers; one for the best exhibit in Group 4, Class 27—gas and air engines; one for the best exhibit in Group 4, Class 28—means of utilising natural forces; one for the best exhibit in Group 11, Hydraulic Machines, &c., Classes 59 to 62; one for the best exhibit in Group 13, Electricity, Class 72—distribution and utilisation of power; and, under the Fothergill Trust, one gold medal for the most novel and best exhibit in Group 28, Philosophical Instruments and Apparatus, Classes 148 to 158. The council proposes to ask the juries in each class to recommend for their consideration either two or three exhibits which they might consider deserving a prize, and it will not be necessary for any special application to be made in respect of these prizes.

ELECTRIC LIGHT IN THE PANTOMIME.—At the Theatre Royal, Nottingham, Mr. Thos. W. Charles's pantomime, "The Forty Thieves," has been produced in magnificent style, each of the forty thieves carrying three incandescent lamps—one in the shield, one in the spear, and one in the helmet. With captain and officers this makes 129 lamps, which require 376 elements, while five gallons of solution are consumed at each performance. Each of the forty carries a 9-cell bichromate battery, three cells being used for each of the three lamps. The whole battery measures 8in. by 2½in. by 4in., and the wires are mostly inside the dresses. The connections (486 in number) require to be made quickly and securely, as the changes from one scene to another are very rapid. There are 376 zinc and 752 carbon elements, the carbons being double in each cell. There are also 1,640 electric contacts to be made good before the lamps can be lighted. Messrs. Oppermann Brothers, of London and Chicago, are the makers of the special lamps for the ballet; and the electric room is under the superintendence of their agent, Mr. G. E. Smith, while Mr. T. Willoughby has care of the batteries.

ELECTRIC LIGHT FOR HACKNEY.—At a recent meeting of the Hackney District Board of Works, the General Purposes Committee brought up a report on a letter recently received from the Jarman Electric Lighting Company, asking permission to open certain paths for the purpose of laying mains from their works at Mackintosh-lane, Homerton, to Mare-street, Hackney. The committee recommended that the sanction of the Board be given, subject to the company depositing a sufficient amount to reinstate the paths disturbed, and also subject to a proper agreement being entered into for the protection of the Board. Mr. Compton, in moving the adoption of the report, said that certain tradesmen in Hackney desired to use the electric light; and the committee thought permission should be given, subject to an efficient guarantee being deposited. Mr. Cox contended that, before giving any electric lighting company such power, they should know the means of the company, and what advantages the Board, as a public body, would obtain, as it would be granting this company a monopoly. The report was referred back to the General Purposes Committee to consider what arrangements could be made with the company with a view to light the public lamps in the proposed district.

THE TELEPHONE AT DEVONPORT.—The United Telephone Company has opened an exchange at the corner of St. Aubyn-street and Fore-street, in a good position, and purposes to virtually make the town a present of several free wires in due course. It is intended to connect the Albert Hospital and also the principal cab stands. Subsequently, the principal fire engine station will be put in communication with the exchange, and seeing there is no fire station in connection with any organised system but that of the police, this will, in all likelihood, run to the Guildhall buildings in Ker-street; it is also probable that the Post Office will be connected, thus enabling a subscriber to obtain information and probably to get his telegrams forwarded, as it is understood that any corporate body may subscribe, so that its members could individually use the exchange. Private wires already exist, though not in any great number, being available between any two given points at all times, at the convenience of the users. The company has acceded to the terms which the town desired, with certain reservations as to a term of years. The Devonport Exchange, while being a part of the Three Towns system, is the centre of the town's own system; and it is expected that very shortly Saltash will be in communication with the three towns.

ELECTRIC LIGHT AND POWER COMPANY.—At the Bow-street Police-court last week the Electric Light and Power Company and Messrs. Parrish and Goddard, directors thereof, were summoned by Mr. B. Bouler for an alleged contravention of the Companies Act in neglecting to forward to the Registrar a list of members and a summary of shares for the year 1884. Mr. George Lewis defended. The evidence, which was of a very complicated character, showed that several extraordinary meetings had been held during 1884 for the purpose of winding up the company and for reconstructing it, but that no general meeting had been held within that year. The question raised was whether an extraordinary meeting of the company was to be considered as a general one. Sir James Ingham decided that, under the 26th section of the Companies Act, the proceedings against the company could not be sustained. He considered that an extraordinary meeting was different from the ordinary general meeting as prescribed by the statute. He consequently dismissed the summons, but at the request of the complainant granted a case subject to recognisances to the extent of two sureties in £50 each being procured, in addition to a personal recognisance of £100. On Mr. Lewis applying for costs, Sir James Ingham allowed the defendant company and directors costs amounting to twenty guineas.

TELEPHONE "CALL OFFICES" IN MANCHESTER.—In accordance with the terms of the Postmaster-General's license, the Lancashire and Cheshire Telephonic Exchange Company has adopted a course which will doubtless prove advantageous to the commercial community in particular and the public generally. They have established a number of public "call offices" in Manchester, Liverpool, Blackburn, Preston, and other towns where any person, whether a subscriber or not to the Telephonic Exchange system, may speak to any firm or person on the company's list of subscribers. Offices were opened in Manchester on Monday at the following addresses: Walter Carter, 103, Market-street; T. R. Withecomb, Victoria-street; Grey and Shaw, Chepstow Buildings, Oxford-street; C. Midgley, St. Ann's-square; Dog and Partridge Hotel, Fennel-street; Cotton Waste Exchange, Market-place; Central Telephone Offices, 38, Faulkner-street; Telephone Offices, 57, Brown-street; Telephone Offices, Lloyd's House, Albert-square; Turkish Baths (W. M. Heriott), Stevenson-square; W. Woodruff, 107, Oxford-street, Chorlton-on-Medlock; and Joseph Fielding, Cheetham Hill-road. Other offices will be opened at an early date. The charge for speaking within the limits of any town is 3d. for three minutes or fraction thereof, and 6d. for three minutes if the person spoken to is in another town.

DINNERS TO TELEGRAPHISTS.—We are glad to see that there is a more generous desire growing in the public mind to recognise those who, although in Government employ, transact a great deal of business in the interests of the public generally. At the beginning of the month the telegraphists of Swansea held their annual dinner, at which their services were duly recognised by the various speakers, and last week the members of the staff of the Leicester Postal Telegraph Department held their annual dinner, during the proceedings of which some interesting statistical information was given. Among other things it was mentioned that there was an extension of the telephone work of the town, and that a trunk wire was being constructed between Hinckley and Leicester. With regard to the telegraphic work in 1883 the increase of telegrams in Leicester over the previous year was 19,000, and last year there was an increase of 22,000 over the number in 1883. In 1883 the telephone calls numbered 45,148, in 1884 they reached 57,949; in December, 1883, the calls were 3,531; in

Digitized by Google

December, 1884, 6,276, or nearly double. The first fourteen days of the present year the number was 4,297. The largest number of transactions recorded in an hour was 80, the largest number in a day 502—an average of eight for each of the subscribers. Reference was made to overhead wires, and it was stated that in the system pursued in Leicester every possible regard was paid to safety, the best materials were used, and the closest examinations made.

ELECTRICAL CELEBRATION OF NEW YEAR'S EVE.—On New Year's Eve, Mr. Wm. J. Hammer, who superintended the introduction of the Edison light on this side the Atlantic, invited to supper all the "old boys" of the Newark, N.J., High School, "Class of '77," of which he was a member. The members of the class came from all parts of the country to revive the memories of the past, and to witness some novel experiments in electricity. Those who rang the door bell were anxious to let go as soon as possible, as some person had attached an electric wire to the knob. On advancing to shake old classmates by the hand, the new comer accidentally stepped on an electric button, and every light in the house was extinguished. On the lights being again put in circuit, he was requested to take a seat; but he somehow managed to secure a chair that was connected by a wire with other arrangements, and he was surprised to hear bells ring and drums beat in the different parts of the house. The lights were again extinguished, and stars shone from the ceiling, then a skeleton made its appearance and paraded round the room. When the company proceeded to the dining room the lights were again extinguished and the dishes on the table were illuminated by incandescent lamps about as large as a walnut, one of which was given to every one as a *souvenir* of the pleasant occasion. After the new year had been duly ushered in one of the gentlemen was requested to cut the cake, when he found this particular cake to be simply a telegraph instrument, with a number of wires attached, but so ingeniously arranged as to look like a veritable product of the oven.

RATING OF TELEPHONE WIRES.—At the Bristol Quarter Sessions the case of the United Telephone Company *v.* the Bristol Sanitary Authority, being an appeal against the general district rate, was lately heard by the recorder, Mr. C. G. Prideaux, Q.C.—Mr. Poole, for the company, contended, first, that the Telephone Company had no rateable property; and secondly, that the valuation on which the rate had been made was excessive. He pointed out that the assessment to the poor rate was under appeal, on the ground that, if the poor rate was reduced, so must the sanitary rate be. Mr. Philbrick, for the sanitary authority, said that, though any alteration made in the poor rate would affect a sanitary rate made afterwards, it would not affect any intermediate rate; he also observed that there was the question as to whether the company was in possession of rateable hereditament The telephone company in Lancashire appealed to the Divisional Court, which held that the wires were rateable; the company went to the Court of Appeal, and the Master of the Rolls and Lord Justice Lindley dismissed the appeal on the ground that the wires and attachments occupied a portion of the buildings to which they were affixed with so much of the soil as was necessary to support them, and that the company had such exclusive occupation of the land as to make them rateable, when leave was given to appeal to the House of Lords. The sanitary authority was seeking to enforce a public burden for the public benefit, for the public had a right to expect that, if the company was liable to be assessed, it should not be omitted from the rate. The appeal was adjourned to the next Quarter Sessions.

ELECTRIC LIGHT AT A BALL.—A very rapid installation of the electric light was completed last week by Messrs. Woodhouse and Rawson on the occasion of the bachelors' ball which took place at the Crown Hotel, East Grinstead. The interior of the rooms was lighted by incandescent lamps, and the exterior of the building and the High-street by arc lights, which burned with remarkable brilliancy and steadiness, illuminating the street on either side for a considerable distance, the effect being greatly enhanced by the fact that the ground was covered with snow, making it to have all the appearance of daylight. The installation consisted of two Marshall engines of 7 horse-power, two Bürgin machines, 100 Woodhouse and Rawson incandescent lamps, and two Crompton arc lamps of 3,000 candle-power. The whole of the wiring in the house was completed with sufficient care for a permanent installation, the joints being all carefully made and properly insulated. The electroliers, designed specially for the purpose, were completely covered with evergreens, eight being used in the ball room with four lights each, and four in the supper room with eight lights in each, the others being similiarly distributed in the sitting rooms, hall, and passages. The whole of the work was completed in three days, the dynamos only arriving late the night before the ball. In addition to this, a shed 25ft. by 40ft. had to be constructed for covering over the engines and dynamos. The plant was started for the first time at four o'clock on the afternoon of the day of the ball, and ran throughout the ball, which was kept up until 4:30 in the morning, without a break or a stoppage of any sort, giving great satisfaction to all present.

TELEGRAPH AND TELEPHONE WIRES.—On January 15th, at the meeting of the Marylebone Vestry, a report was submitted from the representatives of St. Marylebone at a conference of delegates from the vestries and district boards of the metropolis, convened by the Wandsworth District Board of Works, upon the subject of the future control of telephone and telegraph wires along and over the public thoroughfares. Mr. J. R. Endean, the chairman, brought up and moved the adoption of the report. It stated that the President of the Local Government Board having declared it to be the intention of Her Majesty's Government in the next Session of Parliament to obtain a select committee to ascertain the best mode of dealing with telegraph and telephone wires, the conference unanimously approved of such inquiry being made. They had drawn up suggestions for the Parliamentary Committee based upon the principle that no authority, whether existing or to be created, is or can be better qualified to govern and control all wires, whether laid or elevated, than the existing local authorities. First, that they are the only existing authority by and under whom all matters connected with the streets and thoroughfares are governed; secondly, they have recently proved that they are not only qualified but are fully prepared duly and efficiently to discharge all duties connected with telegraphs and telephone systems that future legislation may require at their hands; thirdly, the creation of a new and independent power for these wires only would be certain to create unnecessary and undesirable friction between district authorities, with no beneficial result, and that instead of the creation of a new governing body for such purpose only, all functions required could be discharged readily by the existing street authorities without any material cost to the ratepayers. The report further recommended that the Metropolitan Board should be the first Court of Appeal.—The adoption of the report having been seconded, Admiral Oliver and Mr. Sedgwick objected to the second paragraph as being too self-laudatory and arrogant, and moved as

Digitized by Google

an amendment that it be expunged; but on being put it was negatived, and the adoption of the report carried by a large majority.

SHIP LIGHTING.—Messrs. John Elder and Co. have just launched, for the New Zealand Shipping Company, a steel screw steamer, a sister vessel to the steamship "Kaikoura," launched in September last. The principal dimensions of the vessel are as follow:—Length between perpendiculars, 420ft.; length over all, 451ft.; depth, 33ft. 4in.; with a gross tonnage of about 4,500 tons. The engines will indicate about 4,000 horse-power, are compound surface-condensing, with two inverted cylinders, one high-pressure 46in., and one low-pressure 88in. diameter, adapted for a stroke of 4ft. 7in. The high-pressure cylinder has a valve of the equilibrium-piston type, and the low-pressure cylinder has an ordinary double-ported side valve. These valves are worked by the usual double excentric and link motion. The propeller blades are of manganese bronze, with which material the blades can be cast with fine edges and a smooth surface. The steam is supplied to the engines by three cylindical double-ended multitubular boilers of steel, to be worked to 110lb. pressure per square inch, having in all 18 of Fox's patent corrugated furnaces. Accommodation is provided for 87 first-class passengers on main and spar decks. There is also accommodation for 82 second-class passengers on the main deck, and for 250 third-class passengers forward. The state rooms, which are unusually large, will be fitted with all that can add to the comfort and convenience of the passengers for a long voyage. The main saloon is in the mid-ship portion of the ship, immediately abaft the engine room, and will be a large, elaborately-furnished apartment 42ft. by 32ft. Over the centre of the saloon is a well, 18ft. by 12ft., with a large pavilion skylight on the hurricane-deck above, giving ample ventilation, and making the total height of the saloon fully 17ft. The ladies' boudoir, which is fitted immediately abaft the saloon, will be finished in a handsome manner. The saloons, entrances, corridors, ladies' room, smoking room, card room, state rooms, engine and boiler room are all fitted throughout with the electric light on the incandescent principle; but independent of the electric light the vessel is provided throughout with oil lamps of the most improved principle. The greatest care has been taken in the lighting, ventilating, and sanitary arrangements.

"ABUSE OF THE TELEGRAPH."—The Committee of the Stock Exchange, according to the *Standard*, decided on the 19th inst. to expel the Exchange Telegraph Company from the interior of the building, and three months' notice will accordingly be given to determine the company's tenancy. On this the *Pall Mall Gazette* remarks that the "jobbers," who are the real mainstay of gambling on the Stock Exchange, have succeeded in their agitation to remove the "tape," which, by making known close prices to the public, was an inconvenient impediment to their operations. That a respectable body like the Committee of the Stock Exchange should thus have given way to an agitation which, in plain English, is nothing more nor less than a demand for increased facilities for gambling and befooling the public, will surprise most sensible people. *The Times* says:—"Altogether, we do not see that anyone will lose materially by the decision of the managers in this matter, but neither do we think that any important advantage, public or private, will be gained by it." The *Daily News* says:—"Were the tape' instrument to remain within the House the committee could obviously keep some control over it; but having issued a decree of banishment, it loses all such control, and the tape agency will be at liberty to cut out the jobbers." This it purposes doing straight away by acting on the suggestion of the Royal Commission—namely, by making use of the telephone and the tape to bring buying and selling brokers together without the intervention of the jobber. Immediately on this decision, the Exchange Company issued a circular explanatory of their action, stating among other things, "As some misconception appears to exist in regard to the nature of the plan proposed by this company to facilitate business in 'non-current' stocks by means of our recording instruments, we beg to address you on the subject. It is intended by means of the 'tape' to announce instantaneously and simultaneously to all subscribers, being members of the Stock Exchange, that particular subscribers, also members of the Stock Exchange, are desirous of dealing in particular securities. The method contemplated is simple. A particular broker, being a buyer or seller of a security in which he can get no 'business' price made, and wishing in the interests of his client to find out a real seller or a real buyer, will instantly communicate to this office by telephone (which is already provided with the recording instrument) the fact that he is a dealer in such security. This announcement will be forthwith transmitted to every subscriber by affixing the broker's telephone number to the name of the security specified on the tape. By this means, within a minute and without leaving his office, it will be possible for a broker to lodge a 'notice' of his requirements at the office of every other broker in the Stock Exchange. By the mechanical combination of the 'tape and telephone' it will thus be seen that the physical obstacles of time and space in the constitution of the market are reduced to the minimum. The same result will be obtained as if every member had been personally addressed in the matter, but without the expenditure of the time and exertion occupied in so doing, and with the additional advantage that the intimation will of course bind no one. There are no other means available of securing the same results. Apart from the delay and difficulty incidental to posting 'notices' on the 'pillar,' as described in the Minutes of Evidence taken before the Royal Commission, or the trouble which would be involved in making an 'entry' in a 'register,' such as was suggested in the commissioners' report, it is obvious that a 'notice' when posted, or an 'entry' when made, must be in the nature of the case local, whereas the announcement made in the manner herein described will be widely disseminated. It is not possible to form an adequate opinion of the benefit of this plan in the absence of actual experience, but it has had the favourable consideration of economists as well as men of business, and we submit with confidence that its adoption will be attended by the most satisfactory results. We are not, of course, insensible of the fact that such a system will appear to prejudice certain interests, but we are convinced that the facilities for the transaction of the public business thus afforded will do more than anything else to establish confidence in the Stock Exchange, to the benefit of the general body of members. We think you will agree with us that if you are enabled to offer your clients the same advantages in the execution of their orders as would result from an amount of industry which would be physically impossible, it would conduce to your success, and that such a system in the hands of any outside organisation would constitute an irreparable injury to the market of which you are a member. I will not enter upon the general question of the 'tape,' further than to say that it is now, as ever, the wish of my directors, in all their arrangements, to be in accord with the Stock Exchange, and to take any steps which may be held to further the interests involved."

Digitized by Google

CHARLES ERNEST SPAGNOLETTI.

SPAGNOLETTI, CHARLES ERNEST PAOLO DELLA DIANA; born 1832, at Brompton, was educated at Blennell House, Brompton. On commencing active life, in 1846, he was engaged for a short time in the National Debt Office, and afterwards took an appointment under Mr. Alexander Bain, the inventor of the Chemical Printing Telegraph, with whom he worked until the Electric Telegraph Company opened their central station at Founders-court, Lothbury, in January, 1847, when he commenced his service with that company, representing them in several towns in England, until he entered the service of the Great Western Railway Company, in 1856, as chief of the telegraph department, where he at once began to organise a system, drawing out a book of rules and special codes to meet the requirements of railway telegraphy, which laid the foundation of the regulations now in use on every line in the kingdom, and he has been aptly termed "Father of Railway Telegraphy." The success of his efforts was such as soon to induce other railway companies to follow the example of the Great Western Railway in forming a telegraph department of their own for working their line, instead of leaving it in the hands of the then Electric Telegraph Company, who had hitherto performed these duties for them. When the Metropolitan Railway, in 1865, was opened, it was worked by the Great Western Railway, and in order to meet the requirements of an anticipated heavy traffic and quick succession of trains, Mr. Spagnoletti brought out, in 1862, his disc block instrument for controlling the traffic of this line, and drew out the regulations therefor. On the opening of the District Railway the same system was adopted, as also upon the Great Western Railway, and some other railways at home and abroad. He also arranged this instrument to work on the 1, 2, and 3 wire systems. Finding the effects of lightning were exceedingly dangerous to the working of the block system, by weakening, neutralising, and reversing the signals, he next invented his induced coil, which entirely removed these dangerous results; and this invention is now generally used in all needle instruments, its advantages being so manifest that all railway companies using needle instruments have adopted it. Keeping his attention to improvements in railway working by electrical appliances, he introduced an instrument to indicate to signalmen the position of the "semaphore arm" which they work, when from various causes it is out of the sight of the signalman working it, and also an apparatus for showing him whether the signal lamp is "in" and burning properly or "out" at such signals. He also designed, in the year 1868, a large telegraph board for Ascot racecourse, showing the starters in and winners of the races. This is electrically worked from the weighing room and judge's box, about half a mile distant. This at the time was the largest piece of electrical machinery ever made, and was designed at the request of the Earl of Cork and Orrery, Master of the Buckhounds, with a view of dividing the crowd, which was yearly increasing, and as the rush to obtain the numbers was getting serious.

Mr. Spagnoletti has also patented many other important improvements, such as electrical signals, electrical appliances for working drawbridges over rivers and docks, so that no train can be signalled and allowed to pass over it until these bridges are in proper position; also a system for electrically locking the signal and point levers, so that the signalman at the station in advance may control (as regards sending trains forward) the working of the signals at the station in the rear; and for controlling immediate sidings, drawbridges, &c., and adding to the safety of railway travelling both on double and single lines. The trains by this system performing part of the working themselves, controlling and checking the signalmen; locking block instruments of various kinds; a system of various fire alarms for towns, districts in large cities, and for lunatic asylums and other large establishments; also an electrical bell, by which any number can be worked and kept ringing on a single line wire; an electric tell-tale clock for asylums, by which a record is made of every visit paid throughout the night to each room or particular spot appointed, showing the duration of the visit, and the time occupied in getting from one room to the other. This clock is also applicable to railway signals, so that the exact time a signal arm is either at danger or all right is recorded, and the register can at any time be examined. In the year 1873 he brought out a polarised relay, and in 1881 patented a dynamo electric machine and communication between passengers and guards.

He is President of the Society of Telegraph Engineers and Electricians, a member of the Institution of Civil Engineers, and also member of the Society of Arts, the Dynamicables, and other institutions. He was a juror of the Paris Exhibition in 1878 for the Electrical Department, and member of the Congress and exhibitor at the Electrical Exhibition of Paris, 1881, and received a silver medal; also juror and exhibitor at the Electrical Exhibition at the Crystal Palace, 1882, and on the General Committee and juror of the Electric Lighting Department of the International Health Exhibition of last year.

He has been for 28 years chief electrician and telegraph engineer of the Great Western Railway, and has led an active and practical life in the development of electrical appliances for the working of railways and in electrical science generally.

On Thursday last Mr. Spagnoletti delivered his inaugural address to the Society of Telegraph Engineers, and although, in the nature of things, we have to write before the delivery of the address, we may venture to think that whatever Mr. Spagnoletti has to say will bear favourable comparison with the remarks of his predecessors.

It is no mean task that the President of the Society of Telegraph Engineers and Electricians has to perform in following in the footsteps of masters both in the theory and in the practice of electricity. We do not know if in the selection of President it is intentional to alternately select a theorist and a practical man. This, however, has been the case during the past few years. Thus Professor Adams succeeded Mr. Willoughby Smith, whose life has been spent in practical work, and is succeeded by Mr. Spagnoletti, another exponent of practice. The society should make itself the centre of electrical progress, and we feel assured that this new President will be heartily supported in all his endeavours to add to the usefulness and lustre of the society.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 180.)

Real transient, and suggested dissipative Magnetic Current.

As the rate of increase of the displacement in a non-conducting dielectric is the electric current, so the rate of increase of $B/4\pi$ may be called the magnetic current. Let it be G. Then

$$G = \frac{1}{4\pi}\dot{B} = \frac{1}{4\pi}\mu\dot{H} \quad \text{. . . (Magnetic current) . . (12).}$$

Like displacement electric currents, magnetic currents are transient only, *i.e.*, they cannot continue indefinitely in one direction, like a conduction electric current. Also, like electric currents in a dielectric, they are unaccompanied by heat generation. In ether, the electric current and the magnetic current are of equal significance.

There is probably no such thing as a magnetic conduction current, with dissipation of energy. If there be such, analogous to an electric conduction current, then let

$$G = gH + \frac{1}{4\pi}\mu\dot{H} \quad \text{. . . . . (13).}$$

Here gH is the magnetic conduction current, which, added to the undoubted magnetic current as in (12), gives G the true magnetic current. g may be scalar, or similar to k, with rotatory ϵ. Multiply by H. Then, using (11),

$$HG = HgH + \dot{T} \quad \text{. . . . . (14).}$$

Here HgH is the rate of dissipation. Compare with (9).

Effect of g in a Closed Iron Ring.

The permanency of state of a steel magnet makes it improbable that g has any existence at all, and that the conduction magnetic current is quite imaginary. But we may inquire what would happen in a closed ring of iron under magnetising force, on the supposition that g exists. Let the ring be uniformly lapped with wire, through which we pass a current from a voltaic battery.

If the radius of the ring be large compared with its section, the core may be treated as straight, and the manner in which the current would rise in the coil and the accompanying core phenomena easily worked out by a slight modification of the corresponding case with $g = 0$ (*Electrician*, Sept. 6, '84, Ex. 2). Let a be the radius of the core, also of the coil of negligible depth surrounding it, having N windings per unit length of core. Let k and μ be the conductivity and permeability of the core, and H (parallel to the axis) the magnetic force at distance r from the axis. The differential equation of H will be

$$\frac{1}{r}\frac{d}{dr}r\frac{dH}{dr} = (4\pi)^2 gkH + 4\pi k\mu\dot{H};$$

whence $J_0(nr)e^{mt}$ is a normal system of magnetic force, if

$$-m = \frac{n^2}{4\pi k\mu} + \frac{4\pi g}{\mu}.$$

Thus the effect of g is to increase the reciprocal of the time constant of every normal system by the same quantity $4\pi g/\mu$; in this respect resembling the effect of uniform leakage along a telegraph line, and having a similar result, viz., to accelerate the establishment of the permanent state. When this is reached, we do not have uniform strength of magnetic force in the core; but, if H_0 is the strength at the axis, that at distance r therefrom is

$$H = H_0\left(1 + \frac{xr^2}{2^2} + \frac{x^2r^4}{2^2 4^2} + \dots\right),$$

where $x = (4\pi)^2 gk$. This is accompanied by core currents parallel to the coil current of density

$$-\frac{1}{4\pi}H_0\frac{xr}{2}\left(1 + \tfrac{1}{2}\frac{xr^2}{2^2} + \dots\right).$$

The coil current will be a little less strong than if $g = 0$; for the work of the battery is spent not merely in supporting the coil current, but in heating the core both by reason of the weak core electric current, and the supposed weak magnetic current gH. The back E.M.F. in the coil will be of strength

$$-F\left\{1 + \frac{R}{4\pi Lg}\frac{1 + \frac{xa^2}{2^2} + \dots}{1 + \frac{1}{2}\frac{xa^2}{2^2} + \dots}\right\}^{-1},$$

where F = E.M.F. of battery, R resistance of coil circuit, and L its coefficient of self-induction without the core—*i.e.*, with air replacing it. Or, since g is to be small,

$$-F(1 + R/4\pi Lg)^{-1}.$$

If $L/R = \cdot 01$ second, $g = 1/4\pi$ would make the back force $= 1/101$ of the battery force, so g, if existent, must be very small.

In the following $g = 0$, so that equation (12) is the equation of the magnetic current.

Cross Connections of Magnetic and Electric Force.

In the foregoing we have been dealing with the direct connection of the electric force and its consequences, electric conduction current and displacement, and of the magnetic force and magnetic induction. We have also brought in the displacement current in a dielectric, and the true current in a conducting dielectric. Also, to balance the displacement current, we have introduced the magnetic current. But so far we have no relations whatever between the electric and the magnetic quantities, which we must have, in order to make a consistent system.

The first cross connection is expressed by

$$\text{curl } H = 4\pi\Gamma \quad \text{. . . . . (15)}$$

H being the magnetic force and Γ the true current. Here "curl" is, like sin and cos, the symbol of an operation. It is so recurrent in electro-magnetism that it may be termed *the* electromagnetic operator. It may be defined with reference to Cartesian co-ordinates thus: If H_1, H_2, H_3, are the three rectangular components of H, those of curl H are

$$\frac{dH_3}{dy} - \frac{dH_2}{dz}, \quad \frac{dH_1}{dz} - \frac{dH_3}{dx}, \quad \frac{dH_2}{dx} - \frac{dH_1}{dy}, \quad \text{. . . . . (16)}$$

But the most useful definition is that which is virtually contained in the fundamental Theorem of Version:—The line-integral of a vector H round any closed curve or circuit (or the "circulation" of H) equals the surface integral of another vector, viz., curl H, over any surface bounded by the circuit. Apply this to small squares in planes perpendicular to x, y, and z successively, and the three expressions given in (16) for the components of curl H follow at once. Apply the theorem to suitably chosen infinitely small areas in any system of co-ordinates and we obtain the proper expressions in usually a far simpler manner than by laborious transformations of differential coefficients. Whilst the expressions for the components vary according to the system of co-ordinates chosen as most suitable for a special problem, the theorem, on the other hand, is universal, and gives us the inner meaning of the operation. It is far the best in general investigations not to employ any system of co-ordinates, but to emancipate one's self from their complexity by employing symbols which only relate to the intrinsic meaning of our operations; besides which there is a great gain in the ease of manipulation. In the present paper the meaning of all forms of expression likely to be unfamiliar are briefly stated, and we shall avoid occupying valuable space by lengthy formulæ.

The operator "curl" is connected with rotation thus: if H be the instantaneous velocity at a point in a moving fluid, curl H is a vector whose direction is that of the axis of instantaneous rotation of the fluid surrounding the point, and whose length equals twice the angular velocity of rotation.

Notice that (15) contains no physical constants. It is therefore, in a sense, a purely geometrical equation. Given a system of magnetic force H, mentally represented by lines or tubes of force mapping out space in one way, by the operator "curl" we find another system of lines or tubes mapping out space into another way, viz., the current lines and tubes. Whether

Digitized by Google

H be wholly continuous or not, the derived Γ is necessarily continuous. The curl of a vector can have no divergence anywhere, which we express by

$$\text{div}\Gamma = 0\ ;\ \text{or,}\ \frac{d\Gamma_1}{dx} + \frac{d\Gamma_2}{dy} + \frac{d\Gamma_3}{dz} = 0, \quad . \quad . \quad (17)$$

which defines "divergence" with reference to Cartesian co-ordinates. The divergence of Γ is the amount of Γ leaving a point reckoned per unit volume. When Γ, as here, signifies electric current, it is continuous; as much current leaves as enters any volume, or the integral amount leaving it, reckoning that entering it as negative, is zero. That (17) is involved by (15) is tested by differentiating the three components in (16) to x, y, and z respectively and adding them, when (17) results.

Given H, we have Γ by (15) perfectly definite. But given Γ (necessarily continuous), H is not definitely fixed by (15). For, on finding one function H satisfying (15) with Γ given, we may add to H any function I such that curl I = 0, without disturbing the relation (15). The nature of I is given by

$$\mathrm{I} = -\nabla\Omega;\ \text{or,}\ \mathrm{I}_1 = -\frac{d\Omega}{dx},\ \mathrm{I}_2 = -\frac{d\Omega}{dy},\ \mathrm{I}_3 = -\frac{d\Omega}{dz}, \quad . \quad . \quad (18)$$

when Ω is a *scalar* function of position, a scalar potential in fact. We require some other condition than (15) to find H completely when Γ is given; this is, that the magnetic induction $\mathrm{B} = \mu\mathrm{H}$, (equation 10) is continuous, or $\text{div}\mathrm{B} = 0$. H is now perfectly definite. If μ = constant, all space equally magnetisable isotropically, then B is the same multiple of H everywhere, hence $\text{div}\mathrm{H} = 0$, so that the proper solution of (15) is that function H satisfying (15) which is continuous, like Γ. But H is not continuous when μ varies from one part of the field to another.

Having now defined "curl," "divergence," and ∇ applied to a scalar function, consider (15) from a less abstract point of view, in the light of the Version Theorem. Let there be any closed circuit in space, whether passing through conducting or dielectric matter is immaterial. The amount of current passing through the circuit in the positive direction (that passing the other way being counted negative) equals the circulation of H round the circuit $\div 4\pi$. The actual distribution of Γ is got by taking the circuit infinitely small and applying it to all parts of the field. Let us, whilst considering a finite circuit, yet take it sufficiently small to make the current pass all one way through it. Then, setting up current through the circuit, we set up magnetic force round it.

But there is another way of setting up magnetic force round the circuit, viz., by motion of the circuit itself in a previously undisturbed electric field. Thus, let there be a steady field of electric force, say in air, with therefore steady electric displacement, and no electric current. Let the closed circuit be a thin wire. When at rest in the field there is no current through it, and no magnetic force round it. But if we move the circuit so that the amount of electric displacement through it varies, there is electric current through the circuit, to be measured by the rate of increase of the amount of displacement through it at any moment; or, in another form, by the number of tubes of displacement added to the circuit per second by the motion of the circuit across them. Hence there will be magnetic force round the circuit, and if it be a thin iron wire, it will become magnetised by the motion in the electric field. In general, the motion of matter in an electric field sets up magnetic force.

As an example, fix a thin circular iron ring in air. Call the line through its centre perpendicular to its plane the axis. Let there be no current or magnetic force in the first place. Now shoot a small bullet, having an electrical charge, through the ring, along its axis. The electric displacement due to the charge will be continually changing; thus, there is a system of electric current in the air accompanying the motion of the bullet. The velocity of propagation of disturbances in air is so great that, unless the velocity of the bullet be *not* a very small fraction of the velocity of propagation, we may neglect the disturbance in the field of force due to the latter velocity not being infinite, and suppose that the bullet carries with it in its motion its normal field of force (radiating straight lines) unchanged. The distribution of displacement current about the moving bullet is then the same as that of the lines of magnetic force that would come from it if it were uniformly magnetised parallel to the axis, or line or actual motion in the real case, and the lines of magnetic force accompanying the displacement currents are circles centred upon the axis, in planes perpendicular thereto, the strength of magnetic force in the air being inversely proportional to the square of the distance from the centre of the bullet and directly proportional to the cosine of the latitude, the equator being the circle on the bullet's surface in the plane perpendicular to the axis passing through the centre of the bullet. (With very high velocity this distribution of displacement current and magnetic force is departed from.) The fixed ring coincides with the lines of magnetic force during the whole motion of the bullet, and is therefore solenoidally magnetised thereby, most strongly when the magnetic force is strongest there, *i.e.*, when the bullet has just reached the centre of the ring, and the current through the ring is a maximum. The current through the ring may be measured either by the displacement current through a surface bounded by the ring, or by the rate at which the ring cuts the lines of electric force (supposed undisturbed) of the bullet.

Next, fix the charged bullet and move the ring instead, so that their relative motion shall be as before. There is exactly the same amount of electric displacement through the circuit added per second as before, in corresponding positions of the bullet and ring, with, therefore, the same magnetic force in the ring and the same magnetisation. Otherwise, however, there is a great difference in the two experiments. In the first case, changing electric displacement or electric current all through the dielectric, the greatest strength of current being at the poles of the bullet; whilst in the latter case the field is practically undisturbed except near the moving ring itself. Compare with the induction of electric force in a ring in a magnetic field first when the field is moving, and next when the ring is moved in the field.

The induced magnetic force per unit length in a wire moved perpendicularly across the lines of force in an electric field equals the amount $\times 4\pi$ of electric displacement of the field crossed by the unit length of wire per second, and is perpendicular to the electric displacement and to the direction of motion. In general,

$$\mathrm{H} = \mathrm{V}\mathrm{D}v \times 4\pi,$$

where D is the displacement of the field, v the velocity, H the induced magnetic force, and V is as in equation (3). There are, of course, corrections due to the reactions set up, due to wire not being infinitely thin, and to finite length.

In electro-magnetic units c in air $= (v_1)^{-2}$ if v_1 = velocity of propagation $= 3 \times 10^{10}$cm. per sec. Therefore, in the case of motion of a thin wire perpendicularly across the lines of force in a uniform electric field of strength E,

$$\mathrm{H} = \mathrm{E}v(v_1)^{-2} = \frac{\mathrm{E}v}{9 \times 10^{20}}$$

Let $\mathrm{E} = 10^{12}$ c.g.s., or 10^4 volts per cm., which is less than the disruption force in air in its ordinary state, then

$$\mathrm{H} = \frac{v}{9 \times 10^8}$$

To get magnetic force of strength 10^{-5} c.g.s., v must equal 90 metres or 300 feet per second.

Magnetic Energy of Moving Charged Spheres.

In passing, I may remark that J. J. Thomson (*Phil. Mag.*, April, 1881) found the magnetic energy $\Sigma\mathrm{T}$ due to a sphere of radius a with an electric charge q moving with velocity v in a medium of permeability μ to be

$$\Sigma\mathrm{T} = \frac{2}{15}\frac{\mu q^2 v^2}{a}$$

I find that the $\frac{2}{15}$ should be $\frac{1}{8}$. Also, he found the mutual magnetic energy $\Sigma\mathrm{T}_{12}$ of two infinitely small spheres at distance r with charges q_1 and q_2, moving with velocities defined by the

Digitized by Google

rectangular components u_1, u_2, u_3, and v_1, v_2, v_3, with u_1 and v_1 the velocities parallel to the line joining the spheres, to be

$$\Sigma T_{12} = \frac{\mu q_1 q_2}{3r}(u_1 v_1 + u_2 v_2 + u_3 v_3),$$

against which I find it to be

$$\Sigma T_{12} = \frac{\mu q_1 q_2}{2r}(2u_1 v_1 + u_2 v_2 + u_3 v_3).$$

I do not know what corrections, if any, have been published, and should be glad to receive information on the point, whether in corroboration of my results or otherwise.

(TO BE CONTINUED.)

TEST OF EDISON-HOPKINSON DYNAMO FOR 250 AMPERES AND 55 VOLTS.

The dynamo is of the latest Edison-Hopkinson type with a short armature. The exterior dimensions are :—Length, 56in.; breadth, 36in.; and height, 60in.; and the nett weight of the machine complete is 32cwt.

The commutator is of copper with mica insulation, and has 40 bars, and is provided with double brushes independently adjustable. The magnets are shunt wound.

Magnet resistance is	7·54 ohms.
Armature „	0·009 „

The dynamo is designed for a continuous load of 250 amperes and 55 volts, and to run at a speed of 900 revolutions per minute.

The efficiency of the machine is deduced from the following figures :—

	Watts	H.P.
Total electrical power developed =	16,246 =	21·78
Loss in magnets ..... =	401 =	0·54
Loss in armature ..... =	720 =	0·96
Power available in outer circuit when run as in test ..... =	15,125 =	20·28

Hence—

Electrical efficiency ..... =	93·1 per cent.
Loss in magnets..... =	2·4 „
Loss in armature ..... =	4·5 „

The following are particulars of the test to which this machine has been subjected :—

The dynamo was arranged for driving by an ordinary strap from a double cylinder engine made by Mather and Platt, and carried on slide rails to permit of the belt being tightened if required. One of Sir William Thomson's graded potential galvanometers was permanently coupled to the machine to give a continuous indication of the electromotive force between the terminals, and arrangements were made for measuring the current by means of a current galvanometer, also of Sir William Thomson's graded type.

The temperatures of the bearings were measured throughout the test by means of thermometers placed in mercury cups attached to the bearings, and a continuous record was kept of the temperature of the room.

The speed was indicated by a tachometer attached to the engine, and the revolutions of the dynamo counted from time to time with a counter.

The load was maintained constant throughout the test, as nearly as possible at 275 amperes and 55 volts, measured at the terminals. This is 10 per cent. above the normal load for which the machine is intended.

The machine was started on December 30th and run for five hours, when the temperatures were taken as follows :—

	°C.		°C.
Room.....	17	Magnets	33
Pulley bearing	35	Armature	76
Commutator bearing	36	Commutator...	70

At the end of twelve hours' run the temperatures were again taken.

	°C.		°C.
Room	20	Magnets	33
Pulley bearing	36	Armature	84
Commutator bearing.	34	Commutator...	75

Again, at the end of twenty-four hours, the temperatures were :—

	°C.		°C.
Room	15	Magnets	33
Pulley bearing	30	Armature	76
Commutator bearing.	29	Commutator...	74

Showing that at the end of twelve hours the maximum temperatures had been reached in all parts of the machine. Subsequently, throughout the entire run of three weeks' duration the temperatures did not vary more than was accounted for by variations in the temperature of the room.

The speed maintained throughout the run varied from 910 revolutions to 925 revolutions, with the full load, and the armature and magnets warm.

The machine was run continuously, stopping ten minutes daily to read the temperatures of the armature and commutator, and for Sunday, until January 6th, when it was stopped in order to take out the armature and have it examined to determine if there were any sign of charring or deterioration in the insulation of the wire, and in order carefully to examine the commutator. The examination was conducted by Mr. Blackburn, on behalf of the Edison and Swan United Company, and no change whatever was observable either in the insulation of the wires of the armature or in the commutator.

It was then decided to run the machine absolutely continuously for a fortnight without any break whatever with the full load of 275 amperes. This test concluded on January 20th.

Throughout the whole of this continuous run of fourteen days there was never the slightest sparking at the commutator, the bearings and magnets remained at a uniform temperature throughout, and the temperature of the commutator at the end of the run was 79° C., practically the same temperature as at the end of 12 hours. One set of brushes was used without change of adjustment for twelve days, and at the end were found to be worn down uniformly $\frac{1}{16}$in.

The commutator was perfectly smooth, and showed no signs of wear or grooving, and the armature had stood the run without the slightest swelling or any sign whatever of change in the insulation.

These tests were undertaken by Messrs. Mather and Platt at the request of the Edison and Swan Company, in order to show the durability of the Edison-Hopkinson dynamo under a long and continuous strain, with a load 10 per cent. in excess of that for which the machine is sold. The conditions of the test were formulated by Mr. Albright and Mr. Blackburn, on behalf of the Edison and Swan Company, and it was superintended by them and their representative, Mr. Creagh, during the entire run.

It proved conclusively that a dynamo of this type may be run continuously without any change in its working parts, or deterioration in the insulation of the copper conductors, or change in their resistance, and that the wear is exclusively confined to the commutator and copper brushes, and that with regard to the former, three weeks' run is not sufficient to produce any visible wear, and that the brushes last much longer than usually supposed, one set of them being capable of lasting quite a year on a machine running on an average three hours every day.

ATLANTIC CABLE BROKEN.—The "French Atlantic" Cable broke down on Thursday, a short distance from land. This is the third Atlantic cable that has come to grief on the other side of the water, in about the same neighbourhood, within the last few months.

THE PUBLIC AND THE TELEPHONE.

Some half playful and wholly innocent observations of ours in *The Electrician* "Summary" for 1884 have, it appears, attracted more attention than we had any reason to suppose they merited. In chronicling a few simple and well-known facts with regard to the Post Office, and its excellent but not numerous telephonic systems, we are accused of being official apologists; and in expressing our opinion that users of the telephone would be better served by a State monopoly, we are, in another quarter, charged with advocating a dog-in-the-manger policy. We may as well dispose of this latter imputation at once by citing the words which have provoked it. We said that "if we had the framing of a policy with regard to the telephonic interests of the country, we would suggest the compulsory purchase of private interests by the State, the extension of underground wires, the lowering of rates, and the opening of every telegraph office as a telephone office." We should have thought this programme radical enough even for the *Pall Mall Gazette*; but our contemporary, although continually advocating State interference in matters of its own choosing, is apparently all for disunion and unrestrained competition when the Telephone Companies are in question. Lowering of rates, extensions such as we cannot hope for under present conditions, and the stoppage of the overhead wire nuisance, are apparently not to be sought for at the cost of a State monopoly. "We have had a lesson of the dog-in-the-manger policy which results from State monopoly," says the *Pall Mall* critic, "in the *telegraphs!*" And so we have—the lesson, indeed, that State monopoly has resulted in our telegraph system being in all respects far ahead of every other system of telegraphs the world over. The *Pall Mall* is not satisfied; neither are we. But this is fact; and as far as it goes it proves that our one dog is a more useful animal than anybody else's whole pack.

But to turn to particulars. We are asked to remember that "invention flourishes best when fanned by keen competition;" and this being so, most people will prefer that "commercial freedom and a healthy competition should rule the roast longer yet." Well, if they really prefer the confessedly inadequate and utterly unorganised systems which are growing up under this healthy competition, we have nothing more to say. We spoke in the public interests; if the public are satisfied we have been grossly misinformed, which we decline to believe; and if the shareholders are content with the prospect before them, we have a very poor opinion of their commercial health. But we think better of their business capacity than to suppose they will long care to hold on to a system which under any conditions possible in the circumstances of this country must result either in retracing their steps at a ruinous outlay or in the compulsory purchase which their newspaper friends profess to deprecate. We have no desire to hurry matters; and the fact that the Post Office has the sixpenny tariff to deal with in the present year ought to have saved the *Edinburgh Courant* from the blunder that we were echoing the official mind. We do not so much as know what the official mind is; but we do know what a telephone is; and when the *Pall Mall Gazette* asserts that invention flourishes best when "fanned by keen competition," and inferentially that the telephone has flourished best under the fanning influence of rival company competitors, it talks as "One who knows" not. Our contemporary over the border argues that because the record of postal telephonic extension is meagre that it is imperfect. We should have thought that the more meagre it is the better the companies would like it; but any stick is good enough to beat the official dog. The quality of the official system, however, is another matter, and tested by evidence which is public property, and has never been disputed, the telephone systems installed and managed by the Post Office are models which it would greatly benefit the public at large if the companies would follow. Had it been otherwise we may be sure official customers, who are not official apologists, would have let us know it.

On one point the *Edinburgh Courant* has misunderstood us. When we said the demand for telephonic extension was "not very pressing," we were speaking of the Post Office. If the demand for postal interference in this line of business is, contrary to what we asserted, very pressing, or at all pressing, the accusation against that department would be that the public, turning from the good services of the companies, demand of the Post Office telephonic facilities which it declines to give. We have never heard of this complaint; and as the *Courant* does not give it that shape, we may infer that there is no ground for it. What, then, does the *Courant* want? It derides the Government's lack of enterprise with one breath, yet with the next denounces our suggestion that the Post Office should extend its enterprise to the whole system. Competitive enterprise is—we speak as business men—about the last thing the companies desire at the hands of the Government, much as the public might desire it. But the simple fact is that to enter into active competition with the companies would be an act of cruelty which the press would be the first to condemn. We have all along consistently maintained that the Post Office ought to have stuck to its rights, and done the telephonic business itself; but having conceded what it has, we hold that it cannot in fairness pursue an injurious policy towards its licencees; and we confess to being rather glad to learn that

Digitized by Google

public demand for its competition is apparently not "very pressing." On the other hand, we hold that the fact of granting licenses to private companies for the performance of State duties—for the Telegraph Act made electrical correspondence a concern of the State—the Government have incurred the responsibility for the acts of those companies. The *Edinburgh Courant* may call this official apology if it pleases; we call it common sense and common equity. If it is a fact—and the *Courant* appears to be far more conversant with official secrets than ourselves—that there was some difference of opinion between the permanent officials and the late Postmaster-General, and that some change of policy is contemplated now that he is gone—all that we have to say is that our apologies, like our criticisms, always have been, and always will be, for measures, not for men. The measure we are here discussing is one of public welfare; and we are not going to be silenced by ill-considered claptrap on the one hand, or inconsequential sermonising on the other. In the leading article immediately above the one in which we are censured for disapproving some of Mr. Fawcett's administrative acts the *Courant* itself makes a vigorous onslaught on Mr. Chamberlain and Sir Charles Dilke on account of their political utterances. Heads of Departments are apparently not more sacred in the eyes of the *Courant* than in ours. The difference is, that we stick to that business which we thoroughly understand.

As we said at starting, we had no idea that our suggestion would be taken so much to heart; but we are none the less certain that it must soon be adopted. And for this reason, if for no other, we have strongly advocated some immediate legislative interference with overhead wires. They will have to be bought some day; and then the country will not only have to pay for them but for putting others underground to take their places. The companies need not be in the least alarmed. Mr. Chamberlain is not yet in a position to demand a ransom for their privileges. What the country has permitted the country will pay for, unless it has grown suddenly and incurably dishonest. Overhead wires having reached the limits of toleration; their confiscation being out of the question; and it being evident that telephonic enterprise in the hands of private adventure will continue to be conducted on "strictly commercial" principles, which in this case mean cheap wires and dear messages, whilst under Government control the system would be worked for the benefit of the community, we are still of opinion that it ought to be compulsorily purchased—the sooner perhaps the better.

CORRESPONDENCE.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is gratifying to find that my short note should have elicited two such valuable letters as those of Messrs. Sprague and Blakesley. With much of what they say I agree heartily. Mr. Walker's long diatribe re-states the substance of an equally diffuse oration, which at the Health Exhibition terminated vaguely and inaudibly amidst growing signs of disapprobation. Its tone is far less courteous than that of the two former correspondents; therefore, I shall only correct certain misrepresentations and pass on to the more pertinent strictures of the other gentlemen.

1. I do *not* hold "that the effects of lightning stroke are not the same as those produced by high-tension electric lighting currents."

2. My "own professional brethren" do *not* "bar the way when an opportunity occurs of turning a terrible lesson to advantage." The *post mortem* made at St. George's Hospital will, I hear, be duly published.

3. I have *not* administered a reproof to the Royal Society.

4. I *am* "aware of the case of a man having lived" sometime "after receiving an electric light current," and then dying from its effects.

On counting up the number of times the expression "may" or "may not" occurs in this letter, I find the total to be eleven. Now this phrase, under the guise of a question, puts forward entirely unsupported and hypothetical assertions. In most instances I should answer "No, it may not," but the real point is not whether it may, but whether it does. My one exception is with regard to the inhibitory action of the pneumogastric nerve on the heart. Here I am inclined to agree with Mr. Walker; but at present proof is scanty, and this he does not supply. When evidence is obtained, it will add a fourth to my three suggested modes of death, that namely by syncope.

Lastly, I sincerely hope it will not be necessary, in a matter so important, to arrive at Mr Walker's lame and impotent conclusion, that "the question of the resistance of the body *per se* is very much like the size of a piece of chalk." If this be true, my measurements are, indeed, as he tells me very politely, "so much time wasted." I will waste no more on him.

Turning with relief to Mr. Sprague's far abler letter, I may note that the figures in his first communication were 5,000 to 10,000 ohms, not 5,000 to 1,000, as given in his second, probably by a mere clerical error. That the "ordinary condition" is one of higher resistance than the instance named, I, of course, freely admit; but as I believe it to be "transitory, deceptive, and dangerous" (the words I wrote), the minimum is far the most important. Nor do I think my sulphuric acid illustration inapt, since it has actually happened to me. On another occasion the spark of a large Ruhmkorff coil distinctly leapt three or four inches across the back of my left hand, and "went in" at a little unhealed wound or abrasion rather than pass through the dry skin of the touching fingers. This also is a possible condition in a workman.

The real point of Mr. Sprague's letter is his sweeping condemnation of the measurement of resistance in electrolytes by means of alternate currents. This method is nowise new. It was employed by Wheatstone, and has been improved by Kohlrausch, whose own meter-bridge I am using. I have not heard its accuracy questioned before. But that the measurements thus obtained are considerably lower than those made with momentary alternated currents from an ordinary battery and bridge I not only do not deny, but have actually published such observations. Mr. Sprague has evidently not seen, or forgotten, papers contributed by me some time back to *Nature*, of which I have a reprint much at his service. My "gigantic clinical clerk" gave from foot to foot with the latter 930 ohms, with the former 650 ohms. I have been inclined to attribute the difference to the far higher E.M.F. of the induction coil, about 40 volts, over the 6 volts of three bichromate cells.

That something of a condenser effect may occur in a moist solid like the human body I am also quite prepared to admit; but it must clearly be a very leaky condenser. In this connection I do not quite understand Mr. Sprague's phrase "conducting capacity." Does he mean conductivity, or capacity, or a combination of both? He also rather begs another question by introducing the word "slight" before electrolytic action as taking place in the body. I believe it often is very far from slight, and, at any rate, shows itself in instant and marked polarisation. This Mr. Blakesley seems to state more accurately as follows: "The capacity will probably be found to be, like that of a voltametric series, variable with the charge." I have published a series of measurements in which this is explicitly stated, and I think in a measure proved. Hitherto I have been occupied with measuring the charging power of the currents used in physiology, which are extremely small, and do not appear to have been measured previously. All this also is in print.

My suggestion of thrombosis as a possible cause of death is not hypothetical, but derived from recorded symptoms, espe-

Digitized by Google

cially in the Birmingham music hall case. The evidence will be far stronger if (as with Mr. Sennett's valuable aid I am anxious to do) we can obtain trustworthy *post mortem* records. Mr. Sprague's suggestion that a wire resistance balanced against the body may act as a short-circuiting shunt rather than as a fair derived circuit has considerable force, though he gives no proof of it; and if it be true it entirely invalidates what has hitherto been considered a safe method. Here he a little forces my hand, by obliging me to disclose an unfinished and what may possibly prove to be an unsuccessful device. I have built a meter bridge, in which the wire is replaced by a trough or tube a meter long, filled with some conducting fluid, such as sulphuric acid. The scale reading is given by a platinum disc or plate, freely movable from end to end. If no error has been overlooked, a thing of which I am not yet sure, one electrolyte will be balanced against a known quantity of another. It has also occurred to me that one man might be put in the bridge against another man, but this idea is still in embryo. It is not dissimilar to Mr. Blakesley's chain of men and dynamometers, which, with my willing and intelligent students, I really might be able to carry out. Your patient toleration of the wanderings and sinuosities of one correspondent's lucubrations is the only possible condonation of my own verbosity (I hope the phrase is parliamentary). Let me then say in conclusion that when a thing supposed to be new is started in science, especially in the electrical department, it seems to set up three counter-forces. First, it is affirmed that it is not new; secondly, that it is not true; thirdly, that it is of no practical importance. This subject is, I hope, passing safely through these three stages of evolution, and perhaps may be ultimately attended to.—Yours, &c., W. H. STONE.

DYNAMO-CONSTRUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to the letter from G. C. Fricker in this week's *Electrician*, it is just what I wanted, and I daresay other students are glad to see it, for it is a question that one does not see treated in the books on electricity. Will Mr. Fricker or one of your other correspondents tell me what is meant by the term ampere turn? Also he assumes a certain E.M.F.; but supposing we are designing a self-exciting dynamo machine, how are we to know what E.M.F. will be generated by A at a given speed and with a given number of turns at a given velocity?

Could you, Mr. Editor, see your way to give the students who read your pages a few papers on designing dynamos, &c., and the laws which govern them?

I venture to say there are more students than myself who read *The Electrician* who have the skill and tools to construct first-class dynamos, &c., but who from lack of knowledge of the electrical portion fail miserably; and you will understand that it is a serious thing for people who have not much money to spend weeks and weeks, about 25s. to 30s. over a dynamo, and then find it does not work. Could you also tell me the price of Silvanus Thompson's "Dynamo Electric Machinery" and the publisher?—Yours, &c., THEO. PARDOE.

12, Cambridge-street, Newcastle-on-Tyne.

[We are arranging for some articles "On the Design and Construction of Dynamos."—Ed. *E.*]

HEATING BY ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Sellon, I fear, takes the word "warning" I employed in a previous letter as applying to his inventions. Such was not my intention, and if my letter is carefully read, "warning" is given to those who might thoughtlessly start arrangements for heating by electricity.

Since writing that letter I find that my figures were far too good, and therefore the worse for electrical heating. It appears from Government experiments, made by Dr. Playfair and Mr. De la Beche, the recovered heat in the case of an ordinary steam engine (3lb. coal per indicated horse-power) is only 2·65 per cent. at the terminals of a good dynamo. The figures I gave were $0{\cdot}1 \times 0{\cdot}75$ of total $= 0{\cdot}075 = 7{\cdot}5$ per cent. recovered, which is three times too good. My desire at the time of writing was in no way to exaggerate the facts.—Yours, &c.,

DAVID SALOMONS.

Broomhill, Tunbridge Wells, 19th Jan., 1885.

SMALL MOTIVE POWER FOR ELECTRIC LIGHTING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Replying to your correspondent "D," I have pleasure in giving some particulars of the small installation at my house.

The motor is one capable of giving out about two horse-power on the brake. The dynamo is one of Messrs. Paterson and Cooper's Phœnix machines. I am able to run sixteen to seventeen lamps of 20 candle-power.

My motor house is a little wooden shed, 9ft. long by 6ft. wide. It contains the motor and dynamo. Outside the motor house I have placed a hopper boiler connected to the motor. The hopper holds nine hours' supply of gas coke, and after the fire is lighted it requires no further attention. My man lights the fire, and starts the motor in the afternoon, and then leaves it, and I see no more of him for the rest of the day. The motor continues to work, maintaining a steady light all the evening. On going to bed I simply shut the damper, and leave the motor running; the fire burns low, and the motor stops. The next morning there is a little fire left in the hopper, and by opening the damper I am enabled to start the motor again should I require it. A continuous fire may be kept in the hopper if it is necessary. I burn about 120lb. of coke from four in the afternoon to nine the next morning—that is running the motor from five to eleven o'clock, and keeping in a little fire during the night.

In addition to the lamps, I have a heating coil in the house, which works from the motor.

The pipes to the coil are ¼in. lead gas pipes, carried into the house in the same manner as gas pipes are usually laid. In my case the pipes run up the walls and along the cornice, where they are out of sight. By this system of heating coils may be placed in any part of the house, and the heat conveyed to them by means of small lead pipes, so small that they may be laid almost anywhere without disfiguring the walls. It matters not how many twists and turns and ups and downs the pipes make.

With the motor it is also possible to supply the hot water cisterns of the houses with water at 120° to 140° of heat, either when the motor is at rest or during the time it is lighting the house.

The motor can be made to light and warm the house, and supply hot water to the bath and other hot water tanks.

The steam pressure employed is below the atmospheric pressure, so that neither the motor nor the heating coils are subject to any pressure whatever.—Yours, &c.,

HENRY DAVEY.

Rupert Lodge, Headingley, Leeds, 19th Jan., 1885.

INCANDESCENT LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will some of your readers who may be versed in the art and mystery of incandescent lamps kindly explain why, if a lamp be arbitrarily called a 20-candle lamp at any efficiency that it may suit the maker to fix, it follows, "*as a matter of course*," that if this lamp be run at 12 or 10 candles, which is much under its "*normal*" candle-power, its length of life *must be very considerable?* As the Commissioners of the Vienna Exhibition have said so, it is to be supposed that the statement has some foundation in fact, otherwise an ignoramus like myself would have supposed it was a joke.—Yours, &c.,

CARBON.

P.S. On reading the passage carefully, I observe the Commissioners have been careful to say "*should be*"—not "must be." Of what use is it to tell us what a lamp "should" do?

THE INFLUENCE OF STRESS AND STRAIN ON THE PHYSICAL PROPERTIES OF MATTER.*

BY HERBERT TOMLINSON, B.A.

The effect of temporary longitudinal traction on the electrical resistance of cobalt was determined by a method similar to that already described in a former portion of this memoir,† and it was found that, like nickel, this metal has its resistance *decreased* by moderate temporary stress, in spite of the changes of dimensions which ensue. Whether the decrease of resistance would be changed to increase, as it is with nickel, by a greater amount of stress, has not yet been ascertained, but should this be the case, the magnitude of the stress per unit area which would suffice for the purpose must be much greater with cobalt than with nickel. As with nickel, permanent extension and rolling diminish the effect of temporary longitudinal traction, so that there is a larger decrease of resistance caused by a given stress with annealed than by unannealed cobalt.

Cobalt is remarkable for the extreme persistence with which the same load, when applied again and again, continues to produce permanent increase of resistance, and probably increase of length, but for a moderate amount of permanent extension the increase of resistance is more than accounted for by the permanent increase of length and diminution of section which take place; so that, as with iron and nickel, the *specific* resistance is *decreased* by moderate permanent extension. The permanent decrease of specific resistance per unit for unit permanent increase of length is, for iron, cobalt, and nickel, 0·02, 1·44, and 2·37 respectively; thus the permanent decrease of specific resistance, as well as the temporary decrease of resistance, is greater with nickel than with cobalt.

Since contrary to the expectation arising from the apparent relationship which exists between the "rotational coefficient" of Hall, and the alteration of specific resistance caused by mechanical stress,‡ cobalt behaved like nickel, and not like iron; the effect of longitudinal traction on the thermo-electric qualities of cobalt was examined, and it was found that temporary longitudinal traction renders cobalt temporarily *positive*, as regards its thermo-electric qualities, to cobalt not under traction, provided there is no magnetic stress acting at the same time on the metal. The results obtained would, therefore, not only be adverse to the above-mentioned hypothesis of the author, but also to Bidwell's theory that the "Hall effect" is due to the joint action of mechanical strain and certain "Peltier effects," were it not that in Hall's experiments the metal is under very considerable magnetic stress, which latter has been proved to alter very appreciably the thermo-electric properties of iron, nickel, and cobalt,§ and under these circumstances both the effect of mechanical stress on the specific resistance‖ and that on the thermo-electric qualities of cobalt may be different to what they are, when there is no magnetic stress acting on the metal.

Longitudinal magnetic stress was found to render cobalt negative thermo-electrical to cobalt not under stress.

The cobalt used was in the form of a strip, and the section, which was fairly uniform throughout the whole length, was 0·06168 square centimetre; the length was 58·4 centimetres, and the mass 29·65 grams.

The value of "Young's modulus" was determined by the method of longitudinal vibrations, the strip being held in the centre, and rubbed along its length with a resined glove.

The effect of longitudinal traction on the electrical resistance of unannealed piano steel was tried, the stress used being eventually increased nearly to the breaking point, with the view of ascertaining whether the increase of specific resistance which had been previously found to follow on moderate longitudinal traction might not be changed to decrease. This was not the case; but, on the contrary, whatever the permanent load might be, a temporary addition to this produced exactly the same temporary effect. The fresh experiments, however, confirmed the results obtained with the older ones, and agreed with these in making the alteration of resistance due to traction, both for unit stress per square unit of area and per unit increase of length, less for steel than for iron.

The electrical resistance of magnesium proved to be temporarily increased by temporary longitudinal traction of moderate amount, but the amount of increase was less than could be accounted for by mere change of dimensions, so that the *specific* resistance of magnesium, like that of aluminium, is *decreased* by the temporary stress. It was found also that *when the permanent load on the wire is very small*, both the temporary increase of length and the temporary increase of resistance due to traction increase in greater proportion than the load. The increase of length, however, increases less rapidly than the increase of resistance, so that when the stress exceeds a certain limit, the above-mentioned decrease of specific resistance is changed to increase. Probably a similar state of things would be found to occur with aluminium.

The value of "Young's modulus" was determined for magnesium, both by the method of static extension and that of longitudinal vibrations, the results obtained by the two methods agreeing fairly with each other. The "simple rigidity" was determined by the method of torsional vibrations.

The value of the "bulk-modulus" was determined from the values of "Young's modulus" and the "simple rigidity" to be $287{\cdot}6 \times 10^6$ grams per square centimetre, and this value agreed with that deduced from a formula given in a former portion of this memoir within 2 per cent. This formula is

$$e_v = 2071 \times 10^6 \times c_v J,$$

where e_v is the "bulk modulus" in grams per square centimetre, and c_v the mean thermal capacity per unit volume between 0°C. and 100°C.

The results obtained from the experiments on the effects of stress on the electrical specific resistance of magnesium are in perfect accordance with the view that there is a relation between the "Hall effect" and the alteration of specific resistance.

The electrical resistance of the alloy platinum-iridium* is *much more increased* by temporary longitudinal traction than that of either of the components of the alloy. On the contrary the electrical resistances of platinum-silver, German-silver, and brass are all *considerably less increased* than is the case with their components. This circumstance would rather militate against the employment of platinum-iridium in making standard resistance coils. The increase of resistance alluded to above is much greater than can be accounted for by change of dimensions, so that the increase of *specific* resistance produced by longitudinal traction is considerably greater than is the case with any of those other metals examined whose resistance is increased by traction.

The alteration of resistance above mentioned at first increases in greater proportion than the load, but, when a certain limit of stress has been reached, the ratio of the temporary increase of resistance to the load producing it begins to diminish, and finally reaches the same value as at first. A tendency to a similar state of things is seen with the other metals, but in none is the phenomenon so pronounced as in platinum-iridium.

The value of "Young's modulus" was determined for platinum-iridium, both by the method of static extension, and by that of longitudinal vibrations, and the results obtained were in fair agreement. "Young's modulus" is with the alloy considerably greater than with the two components, so much so as quite to equal if not to excel the value of the same modulus for piano-steel. The "simple rigidity" got by the method of torsional vibrations is also considerably greater with the alloy than with its components.

Unstretched platinum-silver was found to be thermo-electrically positive to the temporarily stretched metal, and forms a very striking exception to the rule which holds good for most metals, namely, that those metals which are *increased* to a comparatively large extent by traction in *specific* resistance are

* A + sign in this and the next two columns signifies *increase* of resistance on the *application* of stress.

those which are rendered most thermo-electrically *negative* by traction.

A further examination was made of the "critical points" of metals, *i.e.*, points at which there is a sudden increase of the ratio of the permanent extension or permanent change of resistance produced by loading, and the load when the latter is increased by small and equal amounts at a time. This examination ended in the discovery of a *fourth* "critical point," occurring with a load exactly half of that at the previously so-called *first* "critical point;" further, it was ascertained that the four "critical points" are in the remarkably simple ratios 1 : 2 : 3 : 4. Table I gives the loads at the four "critical points," and their relation to "Young's modulus" for all the metals which have been as yet examined.

The above Table I shows not only that the four "critical points" are in the above-mentioned simple ratios, but also that with all metals the value of "Young's modulus" bears a constant ratio to the loads at each of the "critical points."

In Table II. are given most of those results of the present inquiry which can be expressed by numbers.

GARASSINO ACCUMULATOR.—In the new arrangement of accumulator devised by Signor Giovanni Garassino, cylindrical glass cells, like those used for an ordinary battery, contain discs, alternately of lead and ebonite, immersed in acidulated water and connected by metal wires. These accumulators are ready, almost immediately after being charged, to give out electrical energy; and the great thickness and area of the discs permits of retaining the charge for several days without much loss of energy.

THE CINCINNATI ELECTRICAL SOCIETY.

The first year of this society's existence was completed on Dec. 20 last, when the 29th meeting was held, and the first annual report presented. A few persons desiring to study the subject of electricity met every Saturday evening; and, after these meetings had been continued for some time, the Ohio Mechanics' Institute, about the oldest institution in the city, proposed they should join the institute and form an electrical section. The proposition was accepted, and the society met at the institute for the first time on Saturday evening, 23rd February, 1884, and have met there ever since at the regular time with but one exception. The present number of members is eighteen, and the number of new members added during the year is seven. The discussions were voluntary. Members so disposed prepared themselves, and made their own apparatus and experiments. The subjects for discussion were generally taken out of standard electrical books, and treated in the order and manner found therein. The following apparatus and experiments have been made by different members of the society:—A set of instruments illustrating the subject of electro-dynamics, being a multiplier and movable wires for angular, parallel, and sinuous currents; apparatus to show the rotation of vertical by horizontal currents; rotation of currents by magnets, rotation of liquids, solenoids; a Camacho electric magnet, made in sections; an electro-motor, without core to armature; an astatic galvanometer; a thermo and secondary battery; the Wheatstone sliding bridge apparatus; a reflecting mirror galvanometer. With these instruments the principles and experiments for which they were designed were successfully shown, besides quite a number of other original experiments.

EVOLUTION OF THE ELECTRIC RAILWAY: Its Commercial and Scientific Aspect.*

BY DR. W. ADAMS, MEMBER OF THE ENGINEERS' CLUB OF ST. LOUIS.

(CONTINUED FROM PAGE 211.)

Let us for a moment look into the construction of this anomaly. It is composed of two parts, one constituting the "field" of the motor, and at the same time serving as the tyre-supporting portion of the wheel; while the second part represents the "armature" of the motor, and revolves within, and in an opposite direction to, the first. Hence it will be observed that the wheel is formed of two separate and distinct parts, both of which revolve, but in opposite directions. Both parts have a continuous tendency to pull towards each other, the poles of the two electro-magnetic rings, or inductors, being always kept at a minimum distance apart. The two electro-magnetic rings mutually act upon each other inductively throughout their entire length. The inner ring corresponds to the armature of a dynamo machine, and revolves as 3 to 1 of the outer ring, which latter in turn corresponds to the field of a dynamo (Fig. 3). Their relative speeds are maintained through the agency of an epicycloidal train of either friction or toothed gearing, the internal gear being carried by the outer ring or field, while the central, or "sun-wheel," is mounted upon the hub of the armature with an intermediate friction clutch. The intermediate or floating wheel is carried by a frame, forming one with, or rigidly attached to, the car axle-boxes. Thus do all geared parts move together always in line. The armature is mounted upon a hub in the form of a sleeve, which revolves upon the car axle.†

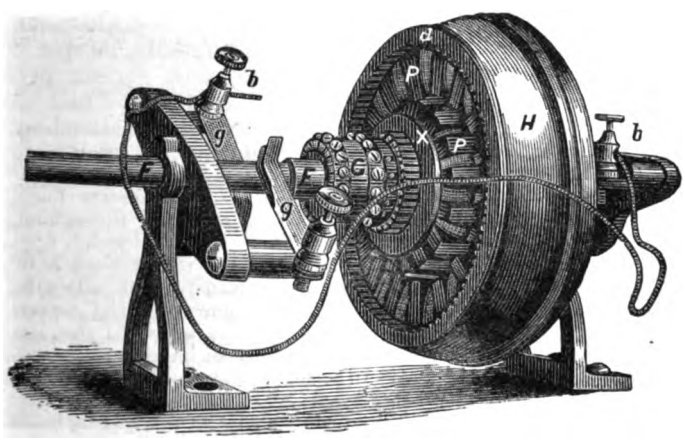

FIG. 3.

Here we have the weight of the machine directly at the point of traction—the tractive power is distributed to every wheel and thus applied directly to the point of traction. The armature may revolve independently of the wheel—hence it may be allowed to attain a high velocity before applying the load, which can be applied slowly and advantage be taken of the impetus of the armature to overcome the inertia of the car on starting. Thus, also, are we not obliged to jeodardise the life of the armature. Again, we are by this arrangement afforded a purely mechanical means of controlling the speed of our car without introducing useless resistance, since by allowing a slip at the friction clutch the armature will run at a proportionately higher speed and generate a higher counter E.M.F., which acts as a resistance and allows less current to pass through the machine, while at the same time the machine is working more efficiently, since its E.M.F. is approaching nearer the E.M.F. of the generator or line. In moving the field as well as the armature, we produce an effect equivalent to increasing by one-third the number of sections in the armature beyond what is mechanically practical, and thus do we raise the electro-dynamic efficiency of the motor. The construction of the motor also is such as to greatly increase the leverage through which the work is done, the pull between the armature and the field being at a considerable distance from the centre. Again, the electro-magnetic construction is such that the armature and the field are subjected to each other's inductive influence throughout their entire length.

This animated wheel is particularly well adapted to one-rail elevated roads, and there is no telling what speed might be attained with wheels like this of from 4 to 6 feet in diameter. In another form I have taken the field from the wheel and made it stationary around the axle between the wheels, the armature revolving as before on the axle, the whole forming an electric truck (see Fig. 4), which is in no way attached to the car, and which may therefore be removed from under or placed beneath a car at pleasure in a few minutes. Here, also, all parts are in line and move together, since the field is rigidiy attached to and forms one with the car-axle box. The power is here transmitted through an epicycloidal train of friction gearing at each end of the armature.

We come now to a detailed consideration of the question of percentage of return. The return of a "dynamo" machine with regard to another which puts the first in motion is expressed by the proportion of the useful mechanical work developed by the second to the work absorbed by the first. This may be estimated in two different ways: first, by appling a dynamometer to the generating machine and a Prony brake to the motor; second, by measuring the intensity or quantity of the current traversing the two machines. In the latter case, the mechanical work absorbed by the first machine and that returned by the second may be ascertained by the electric measurements taken, if we but apply certain fundamental dynamic theorems. Of necessity, such a return would be somewhat higher than that obtained by direct mechanical measurements, since it is simply that which we should obtain in practice if the two machines were perfect—that is, free from friction and certain electric imperfections. Unlike the steam engine, however, which returns us but 10 per cent. of our energy in the form of available work, we get in the electric engine a return of 90 per cent., the above-mentioned sources of loss consuming but 4 or 5 per cent. By Joule's law we can easily calculate the mechanical work developed in the form of heat in an *inert* circuit. This is expressed by one of these three formulæ, RI^2, $\frac{E^2}{R}$ or EI.

The first supposes the resistance (R) of the circuit and the quantity (I) to be known; the second supposes the electromotive force or pressure (E) and the resistance (R) to be known; and the third supposes the electromotive force (E) and the quantity (I) to be known. The last two may be deducted from the first, observing Ohm's law $I = \frac{E}{R}$.

Suppose now that instead of the circuit being *inert* it contained

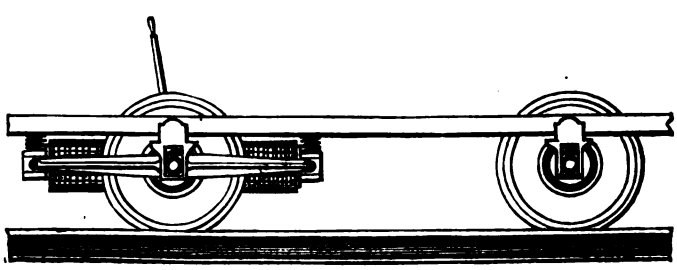

FIG. 4.

a perfect electric motor (the Pacinotti type) free from friction, &c., and provided with a brake.

The total energy developed by the source of electricity now appears in the whole circuit in two different forms: heat and work. The quantity of the current being the same throughout the circuit, the heat developed in the whole circuit is expressed by $\frac{RI^2}{g}$.

The total quantity of the work generated and expended in the circuit is expressed in kilogrammetres per second by $\frac{EI}{g}$.

Supposing, now, T to be the mechanical work produced by the motor expressed in kilogrammetres per second. Then, since the total energies developed by the source equal the sum of the partial energies developed in the whole circuit, we have the equation $\frac{EI}{g} = \frac{RI^2}{g} + T$; whence it follows that we have $T = \frac{I(E-RI)}{g}$ where $E - RI$ represents a negative E.M.F. (e). Hence we conclude that where a motor performs work it necessarily generates a counter E.M.F., and this experiment proves true.

We are now, therefore, brought to the equation $T = \frac{eI}{g}$, or remembering that $I = \frac{E-e}{R}$ $T = \frac{e(E-e)}{gR}$, so that the total energy developed by the source becomes $T = \frac{EI}{g} = \frac{E(E-e)}{gR}$, and the work lost in the form of heat $\frac{RI}{g}$ or $\frac{R}{g}\left(\frac{E-e}{R}\right)^2$ or $\frac{(E-e)^2}{gR}$.

These expressions constitute the fundamental equations of the theory of the electrical transmission of power. Dynamometric measurements have of late proved that the expression $\frac{EI}{g}$ represents about ·95 of the mechanical work applied to the pulley of the generator after deductions are made for the work expended in

* Paper read before the Society of Civil Engineers, America.

† The lecturer here showed several models in operation.

Digitized by Google

overcoming friction—that is to say, if the total work applied to the generator is represented by 100, and the work absorbed by friction by 10, the product $\frac{E I}{g}$ may reach 95-100th of the remaining work (100 – 10) absorbed in purely electric work, or 85·5 per cent. The difference, 90 – 85·5, then represents the loss due to electric inperfections, which I have already said amounted to 4 or 5 per cent.

These fundamental equations enable us to calculate the value of the economic return. For if we call k this return, then $k = \frac{e I}{g} \div \frac{E I}{g} = \frac{e}{E}$.

You notice, then, that this expression is *independent* of the *resistance* (R), so that we may conclude that the economic return depends only upon the proportion between the counter electromotive force of the motor and the positive electromotive force of the generater. This is what M. Deprez tersely expressed when he said, "The return is independent of the distance." The *absolute work*, however, is not independent of the distance. If we would maintain constant the work transmitted, whatever the resistance or distance, M. Deprez has shown that the electromotive force of the source must be increased proportionately to the square root of the resistance. It is a misunderstanding of this point which has led some superficial critics to dispute the results of M. Deprez's work. No rational person would advocate the possibility of transmitting the power of Niagara over a telegraph wire for an unlimited distance. Neither can I conceive of an instance where one would think of putting in a plant to transmit 10 horse-power over a telegraph wire to a point distant 25 miles from the source. Surely, no one would think of establishing a plant for the hydraulic or pneumatic transmission of 10 horse-power to a point distant 25 miles. Why, then, should such absurdities be expected of electricity? In order to see the influence of resistance in the circuit on the absolute work, we must introduce into these equations the value of the return k, which it is *desired* to obtain. From the equation $k = \frac{e}{E}$ we have $e = k\,E$, and making use of this value e in the preceding equations, they become:—

Work absorbed in generator, $\frac{E^2(1-k)}{g\,R}$,

Work recovered in motor, $\frac{E^2 k(1-k)}{g\,R}$,

Work lost in the form of heat, $\frac{E^2(1-k)^2}{g\,R}$.

Thus, the absolute work of the receiver may be the same in two different experiments, although the economic return has very dissimilar values. These differences result from the weight put on the brake. According as the weight on the brake is great or small, so the speed of the receiver is low or high, but the work per second may be the same. This work also may be *nil* in two cases—when $k = 0$, and when $k = 1$.

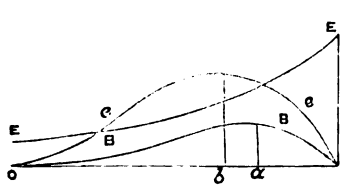

FIG. 5. Knapp's Diagram for Power and Efficiency.

Speeds are plotted as abscissæ, and the electrical work absorbed in watts divided by 746 as ordinates. Then with series wound motors we obtain curve E E, the shape of curve depending on type of motor. Variation of speed obtained by loading brake with different weights. Maximum speed O M. There is a speed at which the external work is a maximum. After loading the brake with varying weights, plot resulting speeds and horse-power as abscissæ and ordinates, which produces the curve B B. $e = \frac{B}{E}$ made with arbitrary scale gives commercial efficiency. Speed for maximum external horse-power is $o\,a$. Speed for highest efficiency is $o\,b$.

This diagram (Fig. 5) very beautifully illustrates geometrically the relationship which exists between the work done and the efficiency, as also the relationship between e and E.

We see from this that there is a value for the economic return, for which the useful work of the motor is the greatest possible. The sum of the two expressions k and $1-k$ being constant, this maximum is reached when they are equal—that is to say, when $k = \frac{1}{2}$. This further gives the result $\frac{E^2}{g\,R}(1-2k)$ of the second term of the second equation. The useful work received therefore becomes $\frac{E^2}{4\,g\,R}$, and the work spent in the generator $\frac{E^2}{2\,g\,R}$. If the receiver were prevented from turning we should have $k = 0$, and the work absorbed by the generator then becomes the greatest possible, or $\frac{E^2}{g\,R}$, the identical value we found for an inert circuit. From this we see that the maximum mechanical work developed by the receiver corresponds to the economical return, being equal to one-half, and that when the economic return is varied between 1 and zero the work spent in the generator constantly increases from zero to $\frac{E^2}{g\,R}$, although the electromotive force remains constant.

It is from not having well comprehended these simple considerations that many have lately written a vast amount of inaccurate criticism on the electrical transport of force. For example, one of the most common of errors is the belief that the economic return can never exceed 50 per cent., because it reaches this value when the work developed by the motor or receiver is the greatest possible in value. We have analogous conditions in thermodynamics, why not apply such reasoning in their case? Take a case in point now of two precisely similar machines, one acting as a generator, the other as motor. Remembering that the current is equal throughout the circuit, and that a constant current produces a uniformly constant field, and that the E.M.F. of a particular generator depends upon its speed and the strength of its field, then it follows that calling the corresponding electromotive forces and speeds of the two machines e, E and v, V respectively, and k the return, we shall have $\frac{e}{E} = \frac{v}{V} = k$. We thus come back to the value $\frac{e}{E}$, which we have already obtained for the economic return by quite a different method.

Regarding the recent experiment of M. Deprez, when it is remembered that before this experiment the boldest enterprise in this direction was a 4 millimetre *copper* wire, 6,400 metres long, with a resistance of only 8·4 ohms, carefully insulated throughout its entire length, and that M. Deprez chose an iron telegraph wire exposed to the rain, 114,000 metres in length, with a resistance of 950 ohms, and that notwithstanding these enormous differences in the conditions of the two experiments, the same industrial return was obtained, namely, 50 per cent., it will be conceded that the Miesbach-Munich experiment was of the utmost importance in the history of the transport of force. In this experiment, notwithstanding the high electromotive force employed (1,400 volts) and the poor insulation of the line, not one per cent. of the current was lost by leakage. It is extremely unfortunate for the engineering profession and the people at large that M. Deprez has been so misunderstood, for it has resulted in the creation of some very erroneous impressions in the minds of some engineers concerning the electrical transmission of power. Let me cite an instance in point: Perhaps some of you have noticed a paragraph going the rounds of your journals to this effect:—"M. Deprez has succeeded in transmitting a current of electricity equivalent to five horse-power along a telegraph wire one-sixth of an inch in diameter, some ten miles long, with an expenditure of 29 per cent. of the power." Compared with wire rope, this means falls short in actual *efficiency* (mark you, *efficiency*), since Messrs Hems send 500 horse-power along a ¾in. rope. Such logic is ridiculous, and should not find place in scientific journals. Pray tell us, in the first place, what has the *efficiency* to do with the respective sizes of the conductors in the two systems; and, second, one might as well impose upon the teledynamic advocates that they transmit their 500 horse-power by means of a ¾in. twine, as to impose upon the advocates of electrical transmission the necessity of using an iron wire one-sixth of an inch in diameter for the transmission of the same power. As a matter of fact we can transmit electrically 1,340 horse-power over a copper conductor of but half an inch in diameter, a distance of five miles, with a loss of but 10 per cent in the line. Aside from the difficulties attending its subdivision and application, the transmission of such an amount of power by a wire rope of like size and over a corresponding distance would be impossible.

(TO BE CONTINUED.)

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 16th January amounted to £4,026.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th January are £2,763, as compared with £2,571 in the corresponding period of 1884.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 16th January were £2,914, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Company.

LEGAL.

Judgment Invalidating Debentures.

EDWARDS V. THE DUPLEX ELECTRIC LIGHT COMPANY.

The further hearing of this case was continued in the Chancery Division (before Vice-Chancellor Bacon), on Friday, Jan. 16.

Mr. MILLAR, Q.C., resumed his argument, and reminded his Lordship that his points were two—1st, that there was no quorum at the meeting at which the resolution was passed sanctioning the issue of the debentures; and, 2ndly, that the debenture deed was not in accordence with the Bill of Sale Act of 1882. At the meeting of the 3rd of May, 1883, Hunt was the only director present. C. Drake was not present at all, and Ilidge did not come in till after the meeting was disposed of. Going through the minute book of the Company, the learned counsel pointed out that there was a committee meeting in May, at which it was resolved that the debenture prospectus be issued, but no fixed scale to be adopted, and that tenders should be received. On May 18 Mr. Ilidge and Mr. Drake were the only two directors present, and at that meeting the mortgage to secure the debentures, which was authorised by the Board on May 8, was approved. What passed at a meeting on May 22nd showed that there were only seven sets of debentures allotted. Several letters of protest from some of the shareholders were read. On May 29th there was a committee meeting, and again only two directors present—Ilidge and Hunt. On that day it was decided with reference to Woodhouse and Rawson's account to offer them debentures as security for the lamps they had supplied, to be returned on payment of the amount, and that portions of the cable should be returned. This offer of a royalty of 3d. a lamp for the right of manufacture was not accepted. He (Mr. Millar) merely quoted the case of Woodhouse and Rawson in order to show one transaction among several in which debentures were only issued as collateral security, to be handed back to the company after having answered a temporary convenience. The liquidator, by whom he was instructed, represented the creditors of the company, and not the debenture holders. Someone must go unpaid, and if the debenture holders were paid the creditors would have to lose their money altogether.

Mr. MARTEN, Q.C.: The trust deed is signed by two directors, Ilidge and Drake, and the debentures by Lily and Ilidge, so that was having three directors agreeing.

Mr. MILLAR, Q.C.: Then my learned friend's argument is this, accepting for the moment the resolution of the directors not to be binding on the company, it has, nevertheless, approved the issue of the debentures, because the bill of sale is signed by two directors; and some debentures which were issued at a different date were signed by one other director, and that, he says, gives the same authority to the transaction as if the three had met together at the Board meeting. But it is quite clear the proceedings cannot be regular if you met one director at the office, one in the court corridors, and another at dinner in the evening, and got each to sign the document. His (Mr. Millar's) proposition was that a quorum of the Board meant a meeting as a Board. Counsel then proceeded to quote the case of Darcy *v.* the Tamar Railway Company. (Law Reports, 2 Exchequer, p. 158.) In this case the secretary had affixed the seal of the Board to a deed, having obtained the signatures of two of the directors at two separate private interviews, the quorum of the company consisting of three. Baron Martin, in delivering judgment in the case, said "that it was not necessary that there should be a fixed place of meeting, but it was quite clear that the directors should act together. Authority had not, therefore, been given as to enable the secretary to affix the seal." Baron Bramwell concurred, adding "that if such a thing was allowable a quorum of the directors might meet at one place and come to one decision, while another with equal authority meet in another place and come to another decision on the same matter." With regard to the second question, viz., whether the deed of trust was valid under the Bill of Sale Act? In the first place there was no schedule of plant annexed as required by the Act, yet singularly enough there was a schedule of the patents, which had turned out not to be extremely valuable. The next objection to the deed was that it did not truly state the consideration. He might mention that the deed, which was dated the 17th May, 1883, had been registered under the Act, though of course that fact alone did not bind them. In the case of Brocklehurst *v.* Eldridge, reported in the *Weekly Notes* of May 15, 1884, which was a case almost exactly similar to the present one, Mr. Justice Field had decided that the deed in question came under the Act of 1882, and required an inventory to be annexed. Also in the case of the National Fund Company the same decision had been come to. He would also bring before the learned Judge the case of Davis *v.* Burton, 11 Q. B. W., p. 537, which came before his Lordship himself, when he said "that this Act of Parliament should be considered with the utmost regard, because it was intended to protect creditors." As to the consideration, it was stated to be as follows:—"That the directors had determined to borrow £20,000 for the purposes of the company." But if this was a truthful statement the deed was not in accordance with Section 8. As a matter of fact, the directors never had to borrow £20,000, and never determined to borrow any such sum. As was shown by the circulars to the shareholders of May 12, 1883, and June 4, 1883, the last being issued within two days of the winding up, when the company were "in extremis." On the first one the shareholders were invited to take up the debentures, and an explanation was given as follows:—Suppose you are a holder of five shares, for which you have paid five pounds each, by expending five pounds further for the purchase of a debenture you will hold a first mortgage security, and be paid in about five years hence, and if the company shall continue very successful you will still have your share in the profits; and the circular of June 4 made it even more clear than the first one. He (the learned counsel) contended that the Board never determined to raise £20,000, but £10,000. And what was the final result? 306 debentures were issued in all, and of these 133 were issued at the rate of £5 each, which amounted to £665. Of the 133, seventy-two were issued after the commencement of the winding-up, and every one knew what would become of them. Some of the 306 were not issued as debentures at all, but as security, which was shown by correspondence with the firm of Woodhouse and Rawson. There was a letter from Dr. Emmens to that firm dated the 3rd July, 1883, enclosing twenty-five debentures to be held against their claim for lamps, to which Messrs. Woodhouse and Rawson replied as follows: "We have to acknowledge the receipt of twenty-five debentures to be held as collateral security against our claim for lamps sold to you and stocked with us." There was therefore this issue to creditors for which the company did not get a shilling. His contentions were therefore these. 1st. There was no deed because the seal of the company was not to attached. 2. Under the Bill of Sale Act 1882 it was void.

The learned counsel concluded by apologising to the Court for having occupied so long a time.

Mr. Edward John Cunningham was then called and examined by Mr. MILLAR, Q.C. He said that he had been in the employ of the Duplex Company previous to the winding-up from September, 1882, to July, 1883, as assistant-secretary. He was acquainted with the books of the company. Dr. Emmens was not a director. In the attendance book W. G. F. Hunt, Chas. Drake, W. Lily, and E. B. Ilidge were put down as being present on the 8th of May, 1883. Only Mr. Hunt was present at the time of that meeting. Mr. Drake was not present at all. Mr. Ilidge came later in the day, after the meeting. No notice was sent to any of the directors of the meeting of the 8th of May. No register of debentures was kept; 386 debentures were issued—133 to shareholders at £5 each; 61 were issued before the 6th June and 71 after. The balance of the 386 was issued to creditors. Some were issued before the winding-up and some after. Only 12 were issued for the consideration of £10 each before the 6th June.

Cross-examined by Mr. MARTEN, Q.C.: Witness was not present at the Board meeting. He was in a room that the directors would pass through. Was not in the office the whole day. There was a private way to the office. Mr. Ilidge could have come in that way possibly. He knew Mr. Ilidge came afterwards, because he was in the secretary's office sometime in the evening and saw him come in.

By Mr. LEVITT: The meeting of the 22nd was held in Mr. Emmens' room. He saw Mr. Ilidge come in; he passed through his room; also Mr. Rushton, the company's solicitor, but did not see him leave. Did not leave the office till late that day—not till half past five. Knew the meeting was over when he left, because he was in Mr. Emmens's room before he left. Could not say what time the meeting was commenced, but presume it was two o'clock, as that was the usual time.

Mr. BEAUMONT said he wished to call Mr. Rushton, formerly the solicitor to the company, but as he was not present, with his lordship's permission, he would call him later on. The learned counsel then briefly addressed the Court on the second point of the defence, adding to the authorities quoted by his learned leader (Mr. Millar) the cases of Davis *v.* Goodman, Hamilton *v.* Chain, 7 volume, 2 B. W., page 719, and that of the Charing cross Advance and Deposit Bank.

Mr. F. S. Rushton was then callen, and examined by Mr. BEAUMONT. He stated that he was solicitor to the company in May, 1883, and prior to that date, and obtained counsel's opinion in reference to the trust deed they were then proposing to execute. The first opinion was obtained on the 7th May, 1883, and the second on the 10th May, 1883. He was present at the meeting on the 8th of May, and arrived at four o'clock. There were several persons present, Hunt, Ilidge, and Dr. Emmens among them. Could not say whether Mr. Drake was present, as he did not know him then. All the questions put to him were put by Mr. Hunt. All the gentlemen present talked with one another.

Cross-examined by Mr. MARTEN, Q.C.: He left a little after six o'clock by the side entrance, by which he would have had no occasion to pass through any other room. The opinion referred to had reference to the powers of the Directors to treat the working expenses of the Company for the first two years as capital, and so to allow them to regard as profit all that was earned by the Company, without regard to the expenses incurred in earning the profit. He had to lay a similar case before another counsel. It was with reference to the issue of debentures and the payment of an interim dividend. The second opinion was practically a corroboration of the first. The point upon which counsel gave opinion was particularly in respect to the question whether the Company could accept the fully paid-up shares as payment for the debentures or as security. There was a question as to, in the event of the Company not being able to take payment for debentures in shares, what discount would it be reasonable to allow to persons to take up debentures at £10 each, and whether the Company could hold out an inducement by saying that they would be returned within a certain time with bonuses.

The further hearing of the case was adjourned till Monday, when

Mr. MARTEN, Q.C., in replying for the plaintiff, said that as to his first point with regard to the validity of the issue of debentures, his lordship would remember that he cited some cases in his opening as to the estopel of the company from disputing the issue so far as regards the power of the directors to make the issue, which Mr. Millar did not in any way touch upon. The Articles of Association set out that the directors might from time to time appoint a general manager, who should have power to act with the power of the Board excepting at Board meetings, &c. In the present case Dr. Emmens had been appointed under that article. The Articles of Association also provided that from time to time the directors could issue debentures, bills of sale, mortgages, &c., provided they were

Digitized by Google

signed by two directors, and countersigned by the secretary or other officer appointed by the Board, and that the seal of the company should be affixed. Here the debentures had been signed by two directors and the general manager of the company. His lordship would remember that he (the learned counsel) in his opening had cited the case of the Romford Canal Company (24 Chancery Division, page 35), which set out that where a Board of Directors have issued debentures, an illegality in the issue cannot be set up against the holder if he has a right to assume "*omnia recta alia*," and in that case the debentures were held to be legal. He therefore submitted upon that, as regards any irregularities in the issue of the debentures, the case was completely precluded by the fact that there was power to issue them in the way they had been issued. Then, the liquidator said the debentures were approved only conditionally, and that three directors were not present. His Lordship had seen the agenda book, which contain the entry of the persons present, and in it the names of three directors had been written. The fact of their being entered in different handwriting did not in the least degree detract from the validity of it, and the other side had not called any one who was present to give evidence as to their absence except Mr. Rushton (the company's solicitor); and he said Mr. Hunt was present, and put the questions to him. Mr. Ilidge, who, it was said, did not come in till after the meeting, was also present, together with Dr. Emmens. The witness then went on to say that there were other persons present at the meeting, but Hunt and Ilidge were the only two he then knew. The other witness, Mr. Cunningham, was a clerk occupying an office in another part of the building, and could not speak of his own knowledge who was present and who not. The fact of his not seeing Mr. Drake go in could be explained by his going in at the private entrance, and the meeting of the company having taken place at half-past three instead of two o'clock. Mr. Cunningham said he did not recollect anyone leaving, and that showed they must have all left by the private way. Moreover, Mr. Rushton said he left by the private way. Looking at Mr. Rushton's evidence, it shows that he knew nothing about this particular meeting at all. In Section 67 of the Companies Act it says: "Until the contrary is proved, every general meeting the company shall have shall be deemed to be duly convened and all acts done shall be valid." Then it goes on to say: "Any minutes of the proceedings shall be received as evidence in all legal proceedings if signed by the chairman and made at the time." Now the minute book of the company is perfectly good evidence against the company, and Mr. Rushton's evidence, so far as it goes, entirely confirms the minute, because he says Mr. Ilidge was present, while Mr. Cunningham's evidence was entirely based upon the supposition that the meeting was held at two o'clock, when it turns out that it was not appointed till three o'clock. Then it was said, admitting that there was a quorum present, the resolution was only "conditional" subject to counsel's opinion. He (the learned counsel) asked Mr. Rushton about that, and he said the counsel's opinion related to some further question, and the result was that the proposal was broadly approved. Then there was a Board meeting, at which Messrs. Hunt, Ilidge, Drake, and Emmens were present, and a series of debentures were then allotted; so he submitted that any question as to informality was out of the question, because they had the meeting at which the debentures were approved. The directors must be assumed to have considered whether the debentures were properly sanctioned by the Board of Directors, and he (Mr. Marten) contended that the question as to the considerution of the debentures completely gave validity to the terms and provisions of the transaction, and that the issue of the debentures was not a mere ministerial act, but one for which each director would be personally liable if they were not properly issued. The defence contended that if three directors were not present the deed must necessarily be invalid, and a case was cited—viz., Darcy *v.* the Tamar Railway Company. That was a case in which the railway company were held not liable upon a deed which had not been executed within the requirements of the Act, but it is totally different to the present case, because all that is required here is the signature of two directors and the secretary. That particular case came under his Lordship's notice in the case of the Bonelly's Telegraph Company, 12th Vol. Equity Cases, p. 246. In that case it was held that the agreement was not *ultra vires*. There was a letter written and signed by two directors, and then handed to a Mr. Collig, who was the claimant, who returned it to the directors after having signed it. He (the learned Judge) said "he quite agreed that 'combined wisdom' was required in that case, he meant that they should all be of one mind, but it was not necessary for them to be all in one place. He could conceive many cases in which the presence of three directors could not be procured. It was not necessary, in his opinion, that what was done by directors should be done in one place." His Lordship went on to say, "the case of Darcy *v.* Tamar Railway Company was referred to by the other side, I may say, somewhat triumphantly. In his opinion the rules were made for the protection of the directors alone." Another case referred to was Cooke *v.* Warne, 2, Common Pleas Division, 305, which says, "Where a Board is constituted by Act of Parliament power must be exercised by them in the concern, and one of them acting alone cannot justify his acts by Act of Parliament," but that was entirely outside the present case. The company could not raise the question and plead the question *non est factum*, because the seal was duly affixed according to the Articles of Association. With regard to the second point, as to the deed not being in accordance with the Bill of Sale Act of 1882, in the first place it did not touch the validity of the deed so far as the patents and uncalled capital was concerned at all. The case which was greatly relied upon on the other side was that of Brocklehurst *v.* the Railway Publishing Company. In that case the execution creditor's rights were in question. In Section 4 of the Bill of Sale Act of 1882 there was an express saving of his rights as against the grantor, and the section said that every Bill of Sale should have an inventory of the chattels and the goods, &c., contained therein annexed. The argument before Mr. Justice Field turned upon the position of matters as regards the execution creditor and the grantor himself. Now Section 17 of the Act said:—"This shall not apply to any incorporate company or affect any mortgage, loan, and security upon the stock and goods of any such company." So he (Mr. Marten) contended that it was quite clear the Act did not apply to incorporated companies. The object was to protect floating securities of this kind, which were very common indeed with regard to companies; but according to Mr. Justice Field's view you could not have any such security, as it destroyed at one blow all debentures. It was said the decision applied to trust deeds, and did not affect securities; but securities relied on the trust deed. It was impossible to register a deed of this description in accordance with the Act, as the security was to be a floating one, and include the subsequent goods as well. The learned counsel then commented on the case of Gardiner *v.* the London, Chatham, and Dover Railway, and went on to say that the Marine Mansions case and that of the Asphalte Company had not been referred to on the other side. It was clear that under the former Act of 1878 these debentures were not held to be within the Act; why then should a different construction be given to the Act of 1882? As to the consideration not being truly stated, he contended that the consideration was truly set forth in the present case, as it said the object of the company was to raise money for the purposes of the company. The learned counsel concluded his address by reading the inquiries, &c., he wished the Court to order, should judgment be for the plaintiff.

Vice-Chancellor BACON, in delivering judgment, said that on the third day of the hearing of this action he was now about to give judgment on the first point at issue. The object of the Legislature was to protect shareholders, and limit and define the powers of the directors, and if those objects were not kept steadily in view in all the transactions of a joint-stock company the transactions were void. What he had to deal with in the case before the Court was whether the directors might borrow sums of money as they thought fit. As he (the learned Judge) understood it, the company having exhausted all its means, the directors, acting under the advice of a gentleman called "Doctor" Emmens, he being present at the Board meeting, for it says in the minutes of what took place at the meeting, there were present Hunt, "the Doctor," Drake, and Ilidge, three directors being required to make a quorum, and he found the following entry: "The consideration of the general manager's suggestion to issue first mortgage debentures." He found no record of any resolution which was come to, but the words were "approved, subject to counsel's opinion," and the minute was neither signed by any director then present nor by any other person. Neither was there any authenticity to the minutes of of May 10, which were signed by Mr. Ilidge. Now, the 67th section of the Companies Act provided that every company should provide minutes of the proceedings of their meeting, duly entered in the books of the company and duly signed, &c. He (the learned Judge) did not find any signatures to that minute, and his opinion was that that minute was illegal. If the company had had entered in the minutes of the next meeting that the minutes of the last meeting were read and confirmed, and that signed by the directors or chairman, possibly that might have given rise to argument; but there was no such resolution, and that made all that they have done "illegal" and "invalid." There was a question as to three directors being present, and upon that question no evidence was clear. There was none on the part of the plaintiff, who might have invited the attendance of Mr. Ilidge or some other person present to prove it. That of the defendants is that Mr. Ilidge did not make his appearance until afterwards. There were two instances, and he was asked to infer that Mr. Ilidge might have crept in through the "Doctor's" entrance; but he would not adopt such opinions, he wanted evidence. If he looked at the book for any purpose he should find all that was entered was that there was an approval of the Doctor's suggestions, provided that counsel should approve of it. And the evidence was that two counsel advised the directors that what was proposed was illegal and could not be carried into effect. The opinions were not produced, and he (the Vice-Chancellor) did not think it necessary that they should be, but the plaintiff was bound to produce some evidence on the subject, and they had got none. Then he was referred to two circulars from the manager to the shareholders, in which he says that the scheme "had been adopted with a view to enabling the shareholders to realise their shares without being affected by the condition of the share market," and explained that if they held shares on which £5 had been paid up, by paying another £5 on each of them they could get a £10 quotation, or in other words a first mortgage on the property of the company, and have the full amount paid off in five years at the most, and that should the company continue to be a success they would still participate in it. That meant this—those of you who are already shareholders in this company, and have contributed £5, which is your money no longer, but the money of the company, if you will give us £5 more we will give you a mortgage for £10. Was that contained in the Articles of Association? In his (the Vice-Chancellor's) opinion it was a clear "fraud," and when he said "fraud" he meant in the sense that all acts *ultra vires* are fraudulent, not otherwise. The transaction, in his opinion, was wholly invalid, and had the meeting been duly convened and the minutes been properly signed, and had it been the intention of the company to raise £10 on each of the debentures to the extent of £20,000, the transaction would have been inequitable and invalid, and altogether outside the duties of the directors, and have been one of those contrivances, which are so numerous, by which witless people, who had trusted their stakes to the company, would play the gambling game for them, be cheated of their stakes, and secure nothing but counters in return. That was enough to decide the case, and upon that ground he proposed to dismiss the action, with costs, as a fraudulent contrivance not authorised by the Articles of Association, and by common sense and justice and for every reason invalid. He did not find it necessary, therefore, to go into

Digitized by Google

the Bills of Sale Act; he relied solely upon the deed which had been executed by the directors. As to the directors having determined to borrow £20,000 for the purposes of the company by the issue of debentures at £10 each, that was not the suggestion of the "Doctor's," and there was not a shadow of an intention to borrow £20,000; but they meant to beguile the shareholders to think that they were bettered in their position by getting a mortgage for £10,000 by paying another £5. He did not think it necessary to go into the Bills of Sale Act. The 17th section of that Act was no doubt a very wide and sweeping section; but, whatever the effect of it might be, was wholly outside the matter now before the Court. In this case, where the interests of the shareholders were placed under the protection of the Court, the question was whether the Company was bound by a deed executed by three persons, and executed in such circumstances as were wholly opposed to the true interests of the shareholders, and therefore he dismissed the action with costs.

Mr. MARTEN said that plaintiff had nothing to do with the creation of the debentures, He simply bought the debentures at par, and represented the creditors who had taken the debentures, therefore his Lordship would be punishing an innocent person by making him pay the costs. He submitted that it would only be fair that the costs should come out of the estate.

The VICE-CHANCELLOR said the so-called "innocent" person came to try and make the shareholders pay that which he had no right to demand, therefore he did not hesitate for one moment in dismissing the action with costs. As to the trustees, they were confederates, and he should therefore give them no costs.

COMPANIES' MEETINGS & REPORTS.

Western and Brazilian Telegraph Company.

The twelfth ordinary general meeting of the shareholders was held on Thursday at the City Terminus Hotel, Cannon-street, Sir Henry Drummond Wolff, G.C.M.G., K.C.B., M.P., in the chair.

Mr. R. M. CUNNINGHAM read the notice convening the meeting and the minutes of the preceding meeting, which were confirmed. The report and accounts were taken as read.

The CHAIRMAN: Gentlemen, you will have seen by the report and accounts that the revenue this year unfortunately shows a diminution of £6,500 odd. This is principally owing to the interruption that took place in the Brazilian Submarine Cable lines, by which we lost about £20,000, or between £20,000 and £25,000; but notwithstanding that, owing to the new arrangements that have been made, I am happy to say that the nett loss was nothing of that kind. Fortunately the Brazilian Submarine Company, with great spirit and energy, proceeded not only to re-lay the line that was broken but they duplicated it, and, therefore, I hope that hereafter we shall have no interruption in the principal feeder of our own line. It may be interesting to the shareholders to know that the reduced tariff at which we are now working has answered remarkably well. I will give you a short statistic of the messages and words which we now carry in comparison with those which were carried previous to the new tariff. In 1882 we carried 44,989 messages of 373,966 words; in 1883 we carried 48,259 messages with 401,782 words; but in 1884 we have carried 101,692 messages with 969,814 words. Thus you see an enormous increase, and that the traffic has considerably more than doubled itself. Well, in the year 1883 the Company carried 57 per cent. of the international traffic, and the Government carried 43 per cent.; but in the year ended September, 1884, the Company carried 90 per cent. of the international traffic and the Government lines only 10 per cent.; and I am happy to say that in the first quarter of this year we have to a great extent recouped ourselves in the losses that unfortunately took place last year, for in the first 16 weeks we have got a traffic of £45,000, against £21,000 last year. Of course the small amount last year was owing to a great extent to the breakage; but that shows a clear gain this year of £24,000. But even on the year before, when there was no breakage, our traffic shows an increase in the first 16 weeks over the traffic in the same period of the year before last of £5,746, notwithstanding that we have reduced our tariff so considerably. Therefore, on the question of traffic and on the question of receipts, I think that the Company has good cause to congratulate itself. Against this excess in the receipts there has been no proportionate increase in the expenses; the increase has only been very slight; but unfortunately we still have to spend a great deal of money on maintenance and the ships. No doubt the ships cost us a good deal of money, but, on the other hand, the presence of the ships there has greatly aided us in the repairs we have had to make, and we have not only made very great repairs, but we have entirely relaid a large portion of our line—to the extent, I think, of 382 miles. This has reduced our unrenewed cable, if I may so call it, to only 450 miles out of our whole system of 2,500 miles. We thought for a long time that this unrenewed cable, which is what I believe is called a deep ocean cable, which is laid in deep water, was safe in the deep sea, so long as it did not come near land; but unfortunately we have discovered that such was not the case, and, therefore, we considered it absolutely necessary for the safety of our system to relay as much as we could last year. The whole system, therefore, consists now of 2,050 miles of sheathed cable, and only 450 miles of the old type, and I think it will be our duty and our policy gradually to go on relaying it until we have nothing but sheathed cable. I do not want to go into past history; but at the same time the shareholders know very well that the present Board is not responsible for the inferior type of cable, and that we, therefore, are really working a rather uphill game in having constantly to spend money on renewing the cable laid in the first instance. The attention of the Board has been very much turned to the question of expense with regard to the ships. As I said before, those ships are and have been perfectly indispensable, and have been very useful to us in enabling us at once to send necessary appliances for the repairing of breakages, as well as for the laying of new cable; but it will also interest the shareholders to know that with the laying of the new cable we expect to have comparatively little repairs; and that in the cables laid South of Rio de Janeiro, which are all sheathed, an expenditure of about five miles per annum appears to be all that is necessary to cover the repairs. Of course there may be accidents, such as those caused by the bad bottom of the sea, or the anchors of ships; but we anticipate that where the sheathed cable lies that is about the portion required for repairs. Now, having come to this point, I wish to say one word on a subject which is not particularly agreeable—it is that of the dividend. Now, no doubt—

Mr. BAKER: You mean the non-dividend.

The CHAIRMAN: Well, the non-dividend, if you like that better [laughter]. But, of course, the shareholders must see that nothing could be more agreeable to the Directors than to be able to declare a dividend if possible [hear, hear]. In fact the objects and the interests of shareholders and Directors are identical.

A SHAREHOLDER: They ought to be certainly.

The CHAIRMAN: Well, I hope they are [a Shareholder: Question]; but at the same time we, the Directors, sitting on this side of the table, who know the state of the Company, the state of its finances, and the state of the cable, have a great responsibility to discharge, and I do not think we should be right in shrinking from it. Therefore, we unhesitatingly say this year that for the interest of the Company, and for the prosperity of the Company, it would be better to pay no dividend [a Voice: Question].

The CHAIRMAN: I think I am speaking to the question [hear, hear].

Mr. BAKER: It is a matter of opinion.

The CHAIRMAN: I think I have the right to use any arguments I think necessary to support my view.

Mr. BAKER: We may differ on this side of the table.

The CHAIRMAN: I shall be delighted to hear you. If you differ from me we will discuss the matter and come to an agreement; but at the same time the shareholders must be aware, as I said before, that studying constantly and throughout the whole year the state of our property we have reasons to arrive at the decision to which we have come. There are a great many differences of opinion as to what is called the life of a cable, and I will not go into that now, because it is rather a long and moot question; but, at the same time, with these views and with the opinions with which we have been fortified by experts and by legal opinion, we think it absolutely necessary that our renewal fund should not be lowered below a certain sum; and as this year we have had to diminish our renewal fund to a considerable extent by reason of the repairs—that is to say, to the sum of £36,000—we think it absolutely necessary to replenish our renewal fund with the £15,000 which might have been applied to a dividend had we considered it right to do so. Therefore, the Directors have not considered it right to recommend a dividend now; but at the same time they think that by this recommendation of theirs—or non-recommendation of theirs—the prosperity and the substantial welfare of the Company is more assured than by giving so very small a sum to the shareholders [hear, hear]. This sum of £15,000 is not paid to the shareholders, but it is no less theirs. It goes to the renewal fund; it goes to the maintenance of their property, and having regard to this, I can only say that to my mind the Company has a very prosperous look out. We have repaired the line, as I have told you, to a very great extent; we have the duplication of the lines of the Brazilian Submarine; we have a large increase of traffic, and we also have a very substantial reserve fund. [Hear, hear.] Therefore, with these four advantages, though I excessively regret that this year we are unable to keep up the dividend, I confidently recommend the report to the adoption of the shareholders. There is one more point I should like to say one word on, and that is with regard to the negotiations which are now going on between the Government and ourselves. Well, I think the policy we adopted in reducing our tariff has, as you see, been successful, and I know that the attention of the Brazilian Government has been directed to the necessity of some understanding with us. I believe this year we are likely to receive in England the visits of certain Brazilian officials, who will be probably empowered to go into the question of some arrangement between us; but until then I think the least said the better, inasmuch as it is useless to raise hopes, which, perhaps, may not be carried out. The negotiations are still being actively carried on, and I trust they will end successfully some day or other. With these remarks, gentlemen, I will move, "That the report and balance-sheet to the 30th September, 1884, be and the same are hereby received and adopted," and I shall be very happy to answer any questions which may afterwards arise.

Mr. W. S. ANDREWS seconded the motion.

Mr. HERRING referred to the rumours which had been circulated before the report was sent out, that no dividend would be paid, and said that although he had read the report very carefully he failed to discover any reason why the profits earned should not be divided [hear, hear]. From beginning to end the report seemed to take the black side of things, and there was an entire absence of the *couleur de rose* element which was usually to be fouud in directors' reports. Amongst other things it was stated that the depreciation of the ss. "Viking" amounted to £1,129; but no special mention had previously been made of such a matter in the reports.

The CHAIRMAN: We did not have the "Viking" before.

Mr. HERRING: Then, why put it here now?

The SECRETARY: Because the depreciation is £1,100 more than last year.

Mr. HERRING then went on to criticise the tone of the report, and said

Digitized by Google

there was no pretext for keeping the shareholders out of a dividend, seeing that £36,000 had been laid aside for the express purpose of converting the strand cable into a sheathed cable. He also considered that the expenses might be cut down. If, however, the Directors intended to use their proxies he would not move an amendment. Would they do so?

The CHAIRMAN asked whether the amendment would be to the effect that a dividend should be paid?

Mr. HERRING replied that he would simply ask the Directors to reconsider the matter.

The CHAIRMAN said, in view of the strong expression of opinion they had had from the shareholders on this question, the Directors would use their proxies in the event of a poll being demanded [hear, hear, and no, no].

Mr. HERRING, after an interruption, moved as an amendment "That this meeting do not adopt the report, but requests the Directors to reconsider the question of the payment of a dividend."

Mr. DYER seconded the amendment.

Mr. CHAPPELL contended that a dividend of at least 2½ per cent. should be paid on the preferred shares, which would absorb £12,000. He asked if the cable in hand, which was put down at £22,000, was of the sheathed type available for present practical purposes.

The CHAIRMAN: Yes, it is.

Mr. SUTTON also advocated the payment of a dividend, and suggested an amendment to the effect that a dividend of 2½ per cent. should be paid on the preferred shares.

The CHAIRMAN pointed out that such an amendment could not be put as it would be out of order. The Articles of Association provided that the shareholders could not increase the dividend recommended by the Board, but they could reduce it.

Mr. DYER protested against the system of sending out stamped proxies.

Major COTTON thought the Directors as large shareholders would have been only too glad to be paid a dividend if they could do so consistently with the interests of the Company [hear, hear]. It was very satisfactory to see that the work done had been so largely increased with only a slight increase in the expenses, and in face of the facts stated by the Chairman, he thought it would be most unwise to press the matter of a dividend to an issue, even if it could be legally done.

Mr. BAKER moved an amendment:—That the sum of £13,000 should be devoted to the payment of a dividend.

In the course of some further discussion, the policy of the Board was supported by Mr. WHITE and Mr. CHALLONER SMITH.

The CHAIRMAN pointed out that the renewal fund had really been built up out of a return of capital, and they had the opinion of Mr. Horace Davey, Q.C., that it could not be appropriated to the payment of a dividend; but besides this the renewal fund as it stood was only just sufficient to maintain the line if the whole of the cable were sheathed. They had 3,000 miles of cable which they were bound to renew sooner or later.

Major WOOD (managing director) said the Directors could not have foreseen the breakages that had occurred 2,000 fathoms below the sea level, nor were they responsible for laying the old strand type of cable. It was most important that the renewals should be effected as rapidly as possible, and therefore, even if the funds in hand could be legally divided, he thought it would be most unwise to do so [hear, hear].

After a few remarks from Mr. ANDREWS,

Mr. HERRING withdrew his amendment, and

The CHAIRMAN ruled that the other amendments were out of order, and declined to put them.

The motion for adopting the report and accounts was put, and declared to be carried.

The retiring Directors, Messrs. Earle and Weaver, were re-elected, and Mr. Weise, the retiring auditor, was reappointed.

The Eastern Telegraph Company.

Report and accounts of the Directors for the half year ended 30th September, 1884, to be presented to the twenty-fifth half-yearly ordinary general meeting, to be held at the City Terminus Hotel, Cannon-street, on the 29th inst., at 1 o'clock.

The Directors submit the accounts and balance sheet for the six months ended 30th September, 1884. The revenue for the period amounted to £309,569 17s. 3d., from which are deducted £84,907 7s. for the ordinary expenses, and £31,189 1s. 3d. for expenditure relating to repairs and renewals of cables, &c., during the half year. After providing £4,439 1s. 7d. for income tax, there remains a balance of £189,034 7s. 5d., to which is added £2,605 11s. 10d. brought forward from the preceding half year, making a total available balance of £191,639 19s. 3d. From this balance there has been paid—Interest on debentures, debenture stock, &c., £26,716 11s. 3d.; dividend on preference shares, £20,559 2s. 6d.; two interim dividends of 1½ per cent. each on ordinary shares, with bonus of 1s. per share (½ per cent.), £114,000, leaving a balance of £30,364 5s. 6d., which is carried forward to the next account. The revenue includes £15,600 dividend for the half year upon the Company's shares in the Eastern and South African Telegraph Company, being at the rate of 8 per cent. per annum, and also £2,023 3s. 5d. net receipts for the half year on the shares of the Black Sea Telegraph Company belonging to this Company. The several sections of the Company's cables, and the land lines in connection therewith, continue in good working order. The building of the new cable steamer "Electra," to replace the "Retriever," was entrusted to Messrs. R. Napier and Sons, on their tender. The ship was successfully launched on the 19th instant. The establishment of telegraphic communication between the islands of the Greek Archipelago, referred to in previous reports, in accordance with the agreement with the Greek Government, was completed by the Company's ss. "Volta" on the 9th August last. A supplementary Convention has been signed for the connection by submarine cable of several other Greek islands. The Directors have concluded an agreement, under a guarantee of traffic, with the Perim Coal Company (Limited), for the connection of the island of Perim with Aden and Suakim by one of this Company's Red Sea cables. The new station was opened for traffic on 31st October. It is expected that the island will become an important coaling station. The Italian Government have now officially approved the transfer to this Company of the concessions and cables of the Mediterranean Extension Telegraph Company, purchased with the sanction of the extraordinary general meeting held on the 24th of January last, and £35,000 of the Company's 4 per cent. debenture stock, the agreed price, has been issued to the liquidators. The action brought by the Central News, Limited, against this Company and others, referred to in the last report, has been finally stayed, all parties agreeing to pay their own costs. In accordance with the provisions of the Articles of Association, two of the Directors, John Pender, Esq., M.P., and the Marquis of Tweeddale, retire by rotation at this meeting, and, being eligible, offer themselves for re-election. The Auditors, Mr. Henry Dever and Messrs. Quilter, Ball, and Co., retire, and offer themselves for re-election.

Cuba Submarine Telegraph Company.

Report of the Directors for the half year ended 31st December, 1884, to be presented at the twenty-seventh ordinary general meeting of shareholders to be held at the Company's offices, 61, Old Broad-street, E.C., on January 28.—The Directors submit, duly audited, the balance-sheet and accounts for the half year ended 31st December last. From these it will be seen that the gross receipts, including the balance brought from last account, amount to £15,710 8s. 10d., and the gross expenditure, including the half of the annual payment on account of the 1881 cable, to £6,119 15s. 4d., leaving a sum of £9,590 13s. 6d. to the credit of revenue account. Of this the sum of £550 has been added to the reserve fund, increasing that fund to £60,000. The dividend on the preference shares will absorb £3,000, and leave £6,040 13s. 6d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 7 per cent. per annum, free of income tax, the balance, £440 13s. 6d., being carried forward to the current half year's account. The Directors have much pleasure in reporting that all the cables have continued in good working order, with the exception of one of the harbour lengths at Cienfuegos, which has become worn out. A new spare length, it will be remembered, was laid in the beginning of last year. A piece of ground has been purchased at Cienfuegos, upon which a store has been built to contain the machinery for the repair of picked-up cable. Tanks have also been fitted up therein for the reception of spare cable. The tax to be returned by the Spanish Government, referred to in last report, has not yet been received.

NOTES.

ATLANTIC CABLES.—The cable of the Paris and New York Telegraph Company is still interrupted.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 23rd January amounted to £3,859.

MACKAY-BENNETT CABLE.—The duplexing of the second Mackay-Bennett cable is now finished, and the Havre section is expected to be laid at the beginning of next month.

COMMUNICATION WITH THE FASTNET.—The cable from the mainland to Lloyd's signal station on the Fastnet Rock has been successfully laid, and vessels signalling that station can now be telegraphed to their owners direct from the rock.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 23rd January were £3,114, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

ELECTRIC TRAMWAY FOR BLACKPOOL.—The Blackpool Electric Tramway Company with a capital of £30,000, in £10 shares, is being actively promoted by some Lancashire gentlemen. The proposed line is to run from the south shore to the north shore.

INTERNATIONAL TELEGRAPH CONGRESS AT BERLIN.—This conference, which was to have been held at the beginning of the present year, is postponed to 10th August, 1885. Official invitations will be issued to all who took part in the St. Petersburg meeting.

ELECTRIC LIGHT AT FRANKFORT.—The first application of the electric light at Frankfort-on-the-Main was made at the recently opened Bauer *café* with 167 Swan lamps fitted to the gas brackets, current being supplied by a Weston dynamo driven by a 20-horse gas engine.

NATIONAL TELEPHONE COMPANY.—We have received the first issue of the list of subscribers to this company in the Inverness district. There are already 46 subscribers in this new district; and three indices, numerical, alphabetical, and classified, have been compiled.

THE DIRECT UNITED STATES COMPANY.—The Board has resolved upon the payment of an interim dividend of 5s. per share, being at the rate of five per cent. per annum for the quarter ending 31st December, 1884, such dividend to be payable on and after the 16th February next.

EASTERN TELEGRAPH COMPANY.—This company notifies that the coupons on their Five per Cent. Debentures due on 1st February will be paid after that date at the banking house of Messrs. Glyn, Mills, Currie, and Company, 67, Lombard-street, London, E.C. Coupons must be left three clear days for examination.

PERSONAL.—Mr. E. J. Erskine, a young electrician, who has been engaged upon the electric light installation for the King of Roumania's country seat at Linia, also at the Bucharest Palace, received, on New Year's Day, a royal recognition in the shape of a gold pin, set with diamonds, and engraved with the king's initials and a crown.

"THE SPECIALISTS' SERIES."—The second volume of this series on "Gas Engines," by William Macgregor, edited by Drs. Paget Higgs and Charles Forbes, will be published next week. There has, we understand, been a delay in issuing this volume, owing to desire to obtain the latest information concerning the most recent motors.

ALTERNATE-CURRENT MOTORS.—The conclusion arrived at by M. Hospitalier in an article on this subject in *L'Electricien* is that alternate currents may produce mechanical work like continuous currents, whether synchronism be insisted upon or variable speed be admitted; but in both cases alternate currents are less convenient and less economical than continuous currents.

ALUMINIUM FOR LEYDEN JARS.—Mr. Levison suggests that aluminium, which may now be beaten out into sheets as easily as gold or silver, be used for lining Leyden jars, the sheets being, of course, thicker than the tinfoil now employed. For an equal surface it would not cost more, would be lighter, and would retain its brilliancy. Fifty sheets of aluminium foil, 4 square inches in surface and of the suitable thickness, would cost about 4s.

DIRECT UNITED STATES CABLE COMPANY.—This Company's main cable between Ireland and Nova Scotia is interrupted. From particulars to hand the cable appears to be broken about 330 knots by cable from Torbay, Nova Scotia, in shallow water, and, weather permitting, easily repairable. During the interruption the company will continue to accept telegrams marked "*vid* Direct Cable," which will be transferred to the Anglo-American Telegraph Company.

POSTAL TELEGRAPHISTS.—We have again to chronicle a festive meeting of postal *employés*. Last week the Worcester postal and telegraph officials held their sixth annual gathering, when good cheer and good wishes ruled the roast. In the course of the evening reference was made to the great increase in the number of telegrams dealt with at this office, no less than 10,000 messages having passed through last year in excess of the number recorded for the previous year.

ELECTRIC LIGHT AT THE CESSNOCK GRAVING DOCK.—Last week the new graving dock and entrance quay to the new Cessnock Docks, Govan, in course of construction, were illuminated by the electric light. The installation, which consists of five Crompton lamps of two thousand candle-power, has been installed by Messrs. Henry Bennett and Co. By means of this light, which is reported as being very satisfactory, the work of constructing the dock will be carried on at night.

ELECTRICAL NOMENCLATURE.—Herr Uppenborn protests warmly, in the *Centralblatt für Elektrotechnik*, against the use of proper names to express electrical measures, saying that if chemists and mechanicians follow in the same direction we may expect to read such items of news as the following:—The boiler of Messrs. X. and Y. burst at a pressure of 100 stephensons; the steels of the A establishment stood an impact of 2,500 trescas; the solubility of ammonia equals 3,000,000 peligots, and so forth.

THEORY OF ELECTRO-DYNAMIC INDUCTION.—At a recent meeting of the Académie des Sciences, Paris, M. Hermite presented a paper by M. P. Duhem on this subject, in which he demonstrates that:—(1) All forces not dependent on distance are annihilated, (2) all action which depends on distance has an infinitely small resultant, and (3) elementary couples are constituted so as to give to the end of each element of length of the conductor a force of the same order as the

Digitized by Google

element, and a finite force at the points where the form of conductor presents a singularity.

ELECTRIC LIGHT IN CALIFORNIA.—This week's *Electricité* illustrates the pyramidal towers made of gas pipes for lighting the town of San José, California. The tower is quadrilateral, the side of the base being about 80ft., while the side of the square at the top is only 4ft., the height being nearly 200ft. The tower is surmounted by a disc, which protects the lamps, and also reflects the light downwards. The six 400-candle Brush lights, supplied by the California Electric Light Company, throw a light that does not dazzle the eyes over a large area, which is better illuminated than by the former gas-burners placed 80ft. apart.

LIGHTING FOR THE "EXMOUTH." — The Metropolitan Asylums Board, 37, Norfolk-street, W.C., announces that it is prepared to receive schemes, specifications, and tenders for lighting by electricity the training ship "Exmouth," now moored in the River Thames, off Grays, Essex. The vessel may be inspected on any week day between 10 a.m. and 4 p.m. by those interested. Sealed tenders, which should state the estimated annual expense of maintenance as well as the actual cost of installation, must be delivered at the offices of the Board, 37, Norfolk-street, Strand, by Saturday, the 14th February, at the latest.

THE WHEELERIES.—Under this designation a large marquee has been pitched on the Thames Embankment for an exhibition of cycles (both bi- and tri-), which opened on the 28th January, and will be continued for about a week. In the evening Mr. Webster, of Maldon, shows some 2½-candle incandescent lamps, maintained by Emmens' portable battery, and adaptable to any kind of tricycle lantern. The electrical bicycle has not put in an appearance this year, probably because the existing restrictions, that every vehicle propelled by other than animal power must be preceded by a person waving a red flag, are too stringent for its general adoption.

ELECTRIC LIGHT AT MADRID.—*L'Electricien* says that a central station is to be established near the Salamanca gate of the Spanish capital for supplying the current necessary to light the greater part of the city. In the ground floor will be the steam engine, dynamos, and workshops, while the upper floors will be taken up with offices and *employés'* residences. There are to be fifteen 100-horse and eight 250-horse engines, with two dynamos calculated to produce, at 150 revolutions a minute, a current of 120 volts at 10,000 amps. The main conductors, of best copper, will be laid underground, their sectional area being calculated for 3 amps. per square millimetre.

ELECTRIC LIGHT ON THE CLYDE.—The No. 2 Graving Dock Works of the Clyde Trustees are being supplied with electric light by Messrs. Henry Bennett and Co., of Glasgow, and the work of construction is being carried on night and day. There are five arc lamps of 3,000 candle-power, three of which light the dock itself, and the other two, hoisted on poles 50ft. high, light the space where the concrete-mixing and concrete cylinder-making is carried on, and the cutting at the dock entrance. The dynamo is driven by a Robey portable engine, and the engine house and approach to it is lighted by a small Grove patent dynamo, supplying currents to five Bernstein incandescent lamps of 30 candle-power each.

SECONDARY BATTERY PATENTS.—Two important and interesting cases with reference to secondary battery patents in the United States have recently been decided. Interferences were raised by Starr and Brush against the Sellon and Swan patents, which belong to the Electrical Power Storage Company; and in both cases the fight has been most obstinately and at great cost contested for nearly two years, appeal after appeal having been heard. The results of the last appeals are that priority of invention has been awarded to both Sellon and Swan as against Starr and Brush. As against Brush the decision on this last appeal is absolutely final, but in the case of Starr a further appeal is still possible.

ELECTRIC TRAMCARS.—Application having been made to the Wandsworth District Board of Works to sanction an experimental electrical car being run on the tramway through Battersea, Mr. Morton moved, at the last meeting of the Board, "That before the consent of the Board be given to the proposal to run electric cars on the tramways, the opinion of an independent engineer or expert be taken, and that the engineer engaged do attend the General Purposes Committee on their visit to inspect the said cars, the fee and expenses of the engineer not to exceed the sum of £10 10s., and such fee and expenses to be paid to this Board by the parties making the application." After a long debate the matter was referred to the General Purposes Committee, with power to act.

METRICAL ABBREVIATIONS.—In commenting on the eight pages of tables relating to electricity and electrical units, added to the *Annuaire du Bureau des Longitudes*, and which are said to be perfectly correct though very incomplete, *L'Electricien* complains that the *Annuaire* does not conform to the indications given in these tables. Our contemporary makes the same strictures as to the metrical abbreviations, which are by no means in conformity with the decisions of the International Committee of Weights and Measures, asking "Of what use are committees, conferences, and congresses if their work is ignored?" But "glass houses should not throw stones." We find, in the same number of *L'Electricien*, that a point is put after the metrical abbreviations, whereas, if we remember rightly, the international committee decided that they should be printed without the point.

ARTIFICIAL GUTTA PERCHA.—This substance is made in the following manner: 50 kilogrammes (110lb.) of powdered copal, with from 8 to 15 kilogrammes (17½ to 33lb.) flowers of sulphur, are raised to a temperature between 126° and 150° C. (259° and 306° F.) with double the weight of turpentine, or with 50 to 60 litres (11 to 13 gallons) of paraffin, being constantly agitated until completely dissolved. To this are added 8 kilogrammes (17½lb.) of caseine dissolved in weak ammonia mixed with a small quantity of alcohol and wood spirit; and the whole is allowed to cool down to 38° C. (100° F.), being again heated to a temperature of from 126° to 158° C. (259° to 306° F.) until it has the appearance of a light liquid. It is then boiled with a solution containing from 15 to 25 per cent. of tannic acid and 500 grammes (1·1lb.) of ammonia. It is kept boiling for several hours, allowed to cool, washed with cold water, and then kneaded in warm water, when it is dried so as to be ready for use.

LIGHTING BY ACCUMULATORS.—Some of the shops in the Passage des Panoramas, Paris, are now lighted by fifty Woodhouse and Rawson 10-candle incandescent lamps, giving out 0·7 amp. at 40 volts, maintained by 22 Faure-Sellon Volckmar accumulators, charged by a Gramme shunt-excited dynamo, driven by a 4-horse Otto gas-engine. The installation was made by Liepmann Frères; and the following are given by *L'Electricien* as the advantages attending the use of accumulators:—(1) Whatever may be the irregularities of the motor, the current

Digitized by Google

sent through the lamps is perfectly constant; (2) the motor always works up to its full power, and therefore economically, whatever be the number of lamps in circuit; (3) the engine need not work all the time the light is required, but only so long as may be required to recharge the accumulators. At present the subscribers are only charged at gas rates for an equal light; but it is hoped that the lighting will be extended throughout the arcade, when the charge will be made by meter.

ANGLO-AMERICAN TELEGRAPH COMPANY.—The Board of Directors has resolved, after placing £37,500 to the credit of the Renewal Fund for the quarter ending 31st December, 1884, to recommend to the proprietors at the next half-yearly general meeting of the company, to be held on the 6th February next, the declaration of the following dividends:—1. A balance dividend of 17s. 6d. per cent. upon the ordinary consolidated stock for the year ending 31st December, 1884. 2. A balance dividend of 30s. per cent. upon the preferred stock for the year ending 31st December, 1884. 3. A first and final dividend of 5s. per cent. upon the deferred stock for the year ending 31st December, 1884. All payable on 7th February next. After paying the foregoing dividends there will be a balance of about £1,500 to be carried forward to the next account. The above dividends, together with those already paid, will amount to £3 2s. 6d. per cent. on the ordinary consolidated stock, £6 per cent. on the preferred stock, and 5s. per cent. on the deferred stock for the year 1884.

TRAIN LIGHTING BY ELECTRICITY.—While the Great Eastern Railway Company with commendable enterprise has carried on electric lighting in some of their suburban trains for months past, and a battle of words is now raging in the pages of a contemporary with reference to this particular system of train lighting, German electricians have not been idle, and have fitted up some trains on the Frankfort-Fulda-Elm line with a dynamo placed in the guard's van on one side and accumulators on the other side. The dynamo, if driven at 750 revolutions, gives a current of 12 amperes, which by an automatic switch is sent into the accumulators. Since the dynamo is driven from one of the axles of the van, it can only charge when the train is in motion and going at a speed of over twenty miles an hour. If the speed falls below this minimum the switch cuts the dynamo off from the accumulators in daytime and from the lamps at night, since during the evening the lamps are fed direct from the machine so long as the train is in motion. On stopping, the automatic switch not only cuts the dynamo out but also puts the accumulators in, thus insuring the continuation of the light at all times. The cost of installing the plant is given at £125 for dynamo, driving gear, and accumulators, and at 65s. to 80s. per passenger coach. The light itself is estimated to cost ·85 of a penny per lamp-hour.

TRANSFER OF CARBON IN THE ELECTRIC ARC.—M. G. Gallice, in *L'Electricien*, says that a simple experiment makes manifest the transfer of carbon particles from one electrode to another in the voltaic arc. If the arc be produced by taking as the negative electrode a carbon 15mm. in diameter, and as the positive electrode a 4mm. carbon, the following phenomenon will be observed:—The negative carbon does not become red hot on account of its volume; but, on the contrary, the positive carbon immediately becomes incandescent and pointed. By degrees the particles of carbon which escape from it are deposited on the negative carbon and there form a small cone, 3mm. in diameter at its base and attaining nearly 4mm. in height, which is continually increasing. It then behaves as would the point of the negative carbon in the ordinary arrangement, with this difference, that the wasting due to combustion is compensated by the deposit of carbon. The light is at this moment brighter than at the commencement, and remain very constant. The cone sometimes breaks, but is soon reconstituted, being formed of a very black carbon, with fine and brilliant fracture, but having less cohesiveness than lighting carbon. A projection of the carbons by means of the photo-electric microscope renders the experiment interesting to follow. The author used a rougly-made Archereau lamp, the luminous point of which is sufficiently constant for optical experiments, while its simplicity and the absence of regulating apparatus render it preferable to hand-regulated lamps, which are often used under similar circumstances.

PROPORTIONAL DEVIATION GALVANOMETER.—In the Deprez and D'Arsonval galvanometer for movable circuit, there is only proportionality between the intensities and the deviations when an angle of four or nine degrees is not exceeded. So that it is always necessary to resort to the mirror when using this instrument; and that is not always convenient, especially in applications of an industrial character. M. Marcel Deprez, in seeking to construct apparatus for electrical measurements, at once simple, correct and of speedy application, has modified the original galvanometer so as to render the deviations exactly proportional to the intensities, even when they attain sixty degrees on each side of zero, which permits of using an index fixed to the movable frame, and working above a graduated sector. The modification made in the original instrument consists in providing the arms of the magnet with two pieces of iron forming between them a cylindrical recess in which is placed the soft iron cylinder. The space between the latter and the two polar pieces forms an intense magnetic field, practically uniform, in which the frame moves. Whatever be its position within the above-mentioned limits, the couple due to the current is always proportional to its intensity; as, on the one hand, the couple due to the suspension wires is proportional to the angle of torsion, it follows that equilibrium is attained whenever the frame has made an angle proportional to the intensity of the current which traverses it. Experiments made in comparison with voltametric methods have proved that, from zero to 60 degrees, the galvanometric constant, *i.e.*, the intensity corresponding to a deviation of 1 degree, varied by about 1 per cent. of its mean value, a quantity of the same order as the other causes of error inseparable from the method of comparison employed.

THEATRE LIGHTING AT MUNICH.—It will be remembered that at the Electrical Exhibition in Munich an experimental stage was constructed and lit by electricity with a view to prove whether this form of illumination be suitable to theatres. The result of these trials, as far as Munich itself is concerned, has been an installation in the Royal Theatre, which is the largest installation yet erected in Germany, except the central station of the Edison Company in Berlin, which, however, is not a private but a public undertaking. The generating power in the Munich installation consists of five Edison dynamos, each capable of feeding 450 16-candle lamps for night work, and one Edison dynamo capable of feeding 250 16-candle lamps for use during daytime. These dynamos are driven by three compound steam engines developing together 350 horse-power. Three boilers, each having 930 square feet of heating surface, supply these engines with steam; and the grates are so arranged as to burn a poor kind of coal, found in Bavaria, and which is unsuitable for the manufacture of gas. The distance between the dynamos and the theatre is about 300 yards; and the current is con-

Digitized by Google

veyed by four copper conductors laid one metre on the ground and taken back to the dynamos by four similar conductors placed by the side of the former. The total area of cross section in the mains is 1·9 square inch, which gives a density of current of about 800 amperes per square inch if all the machines are at work together. The total length of wire throughout the theatre is thirty miles; and the total number of sixteen-candle lamps fixed is 2,500. All the lamps are under control by means of one great central system of switches and rheostats, and several smaller switches and rheostats placed at convenient positions throughout the building. In this manner the most varied scenic effects can be produced, and provision is also made for putting arc lamps in circuit at various places when desired.

Delayed Demagnetisation of Iron.—Sig. Felici's experiments on the duration of magnetisation or demagnetisation were carried out by surrounding soft iron bars with two spirals, one magnetising and the other induced, capable of being opened or closed at very short intervals by the Felici interrupter. In the case of demagnetisation, if the magnetising current be interrupted at the very instant the induced circuit is opened, the induced current will correspond with the total amount of magnetism generated in the iron bar; but, if the induced circuit be only closed at the end of a certain time, t, after the interruption of the magnetising current, the induced current will only correspond with the residual magnetism preserved by the bar at the end of the time t. In this way, Sig. Felici found that the galvanometric deviation F, measure of the quantity of electricity in the induced current, might always be represented by a single exponent

$$F = A\,e^{-\alpha t} + B\,e^{-\beta t}$$

in which A, B, α and β are four constants. If the iron be almost perfectly soft, a single-term exponent will suffice. Sig. Stracciati, experimenting by the method and with the interrupter of Sig. Felici, proved the correctness of his (Sig. Felici's) results, and then turned his attention to ascertaining the influence of the degree of magnetising force, and that of the induced currents which may be developed in the iron mass, when he arrived at the following conclusions:—(1) Felici's formula reduced to a single term represents the results of the experiments so much better as the magnetising power employed is weaker; (2) the speed with which the magnetism of an iron mass is dissipated on the suppression of the magnetising force diminishes, at first rapidly, when this force increases, but it afterwards appears to tend towards a constant value; (3) the speed with which the magnetism is dissipated in a bundle of soft iron wires, which are prevented from touching each other by a few turns of silk only, diminishes appreciably when the conducting mass is rendered continuous by the aid of a mercurial bath in which the bundle is immersed.

Lighting a Mill by Electricity.—The experiment of lighting various rooms in a mill required for different manufacturing processes has been successfully carried out at the extensive woollen manufactory of Messrs. J. Taylor and Sons, Colne-road, Huddersfield. During the past year, and recently, the firm decided to largely increase the use of electric lighting in their works. The number of incandescent lamps in use for about twelve months has been 200, but Messrs. Taylor and Sons have now enlarged the area of lighting, and have just had put down a large Victoria Brush compound self-regulating dynamo, capable of lighting 700 or 800 incandescent lamps, and arc lights if required. At present they have 400 incandescent lamps of 20 candle-power each in operation in the warping, weaving, mending, knotting, and finishing rooms, the yarn store room, the pattern rooms, the warehouses and offices, as well as two powerful arc lamps. The dynamo is placed in the engine room, and is driven by the same engines that drive the general machinery of the mill. The power required to drive the electric machine is about forty horses. There are six circuits, each of which can be used separately from any of the others, and the supply to any of the six may be switched off whenever requisite. The result of the change from gas to electricity as a method of lighting is that in the rooms where the incandescent lamps are in use the air is purer, and there is no oppressive heat, while the lighting is all that is needed for the workpeople to perform by its aid the various operations required in the different manufacturing processes. In conversation the operatives say that they greatly prefer the electric light to the gas-light; that they could see to do their work better, and with greater comfort to themselves. The contractors for this increase of electric lighting of the works of Messrs. J. Taylor and Sons are Messrs. Thomson and Ritchie, who supplied the original installation, and who have entrusted the present work to Messrs. Woodhouse and Rawson, of 11, Queen Victoria-street, London, and it has been carried out under the superintendence of Mr. Reginald Laurence, A.M.I.C.E.

Electric Signals for Mines.—Mr. Sydney F. Walker, who has had much experience in applying electric signals to mines, considers that the most useful signal, and the one of which the greatest number are in use in collieries and iron mines, is that for engine planes. This consists of an electric bell and battery which are placed in the engine house, and two wires that extend from the engine house to the end of the plane, being connected to the bell and battery. For collieries, these wires are of naked galvanised iron, and, where the engine is on the surface, two wires are carried from the engine house down the shaft, being then connected to the wires on the engine plane. One of the wires in the shaft is of copper, covered with gutta percha. In both cases the signal is given by making connection between the naked iron wires at any part of the plane. The single stroke bell is the one most frequently used in mines, though sometimes, however, a vibrating bell is preferred. If required to signal at the end of the plane at the same time as to the engineman, the same battery and the same wires may be used to ring a second bell at that end, in which case the connection between one of the wires on the engine plane and one side of the bell is broken. The engine plane wire is left disconnected, the bell on that side being now connected either to "earth"—as the rails, the engine, &c.—or to a third wire, fixed for that purpose, extending to the end of the plane. This third wire, in this case, need not be insulated; but it may be stapled out of the way. At the other end of the engine plane, a second bell is connected between the wire which has just been disconnected from the bell in the engine-house and "earth" or the third wire. When connection is made between the first two wires, the current passes from the battery through both bells, returning either by "earth" or by the third wire, this third wire being necessary where the mine is very dry or it is difficult to maintain good "earth" at the end of the plane. It may be required to have a number of bells in different parts of the plane, all of which shall ring together, as before, from anywhere. The principal advantages of electric signalling for mines are stated by Mr. Walker as follows:—(1.) The signal is transmitted instantaneously. (2.) Any number of knocks may be made in rapid succession. (3.) Signals can be made to and from any number of places, all together, separately, or in any number that may be desired. (4.) The wires may be carried round curves, and in any direction, even in a tangle,

Digitized by Google

without in the slightest degree affecting the efficiency of the signal. (5.) The wires once properly laid need no repairs. There is no consumption of material except in the battery; and that with proper insulation is very small indeed. (6.) These signals are easily kept in repair, far more easily than hand rappers. (7.) Telephones may be worked in connection with them.

STRANGE IF TRUE.—A curious example of the force of imagination is reported from Philadelphia. Dr. George C. Harlan, surgeon to the Wills Ophthalmic Hospital in that city, in the current number of the *Medical News* reports a curious case, showing the great influence of the mind upon the body, and the beneficial effects of a wooden magnet upon both. A young Philadelphia woman, Lizzie D. by name, applied at the Polyclinic, Thirteenth and Locust-streets, for relief from a disease of the tonsils. She was treated by Dr. Solis Cohen. Her disorder was attended with hysteria, and, like all hysterical people, the idea of being doctored filled her with delight. Shortly after her admission the nervous symptoms became more and more marked, and she was transferred to the care of Dr. Mills, the well-known neurologist. Five or six weeks previously she had had pleuro-pneumonia, and after that paralysis attacked the arms. This was cured, but the disease manifested itself in the legs and feet. Besides this there was a numb feeling in the lower part of the body, and twitching on the right side of the face, similar to that seen in St. Vitus' dance. Dr. Cohen applied a Charcot magnet in front of the ear. To his amazement the spasms on the side of the face touched by the magnet were greatly lessened in frequency and extent. It was evident that the cure was the result of imagination. After that she was attacked with eye troubles. At first there was no defect other than headache, after the prolonged use of the eyes, and some shortsightedness, but at length the right eye became, apparently, entirely blind, and muscular spasms of the most violent character disturbed not only the eye but the face and neck. She was sent to the Eye Hospital, and treated by Dr. Hansell. After several examinations, the Charcot magnet, that had proved so efficacious in the hands of Dr. Cohen, was applied to the defective vision, and with the most astonishing result. After many applications it occurred to Dr. Harlan that it would be a good idea to try the effect of unmagnetised iron of the same form and appearance of the magnet. A wooden "magnet" was procured, with iron tips, to give the metallic impression to the skin. It was placed in the drawer where the original Charcot instrument had been kept, and the patient was thoroughly ignorant of its character. Before the application it was noted that the pupil of the right eye was widely dilated, as in disease, and was perfectly rigid when exposed to a bright light. There was twitching of the muscles on the right side of the face. The application of the wooden magnet had a wonderful effect. Shortly after the painted wood was applied with much seriousness to her head, the twitching of the muscles stopped, and the face assumed its normal appearance. Gradually the pupil of the right eye became of the same size as the other, and freely responsive to light. The wooden magnet had triumphed. Dr. Cohen a short time ago had a case where the wooden magnet proved its efficacy. A patient of his fell down, and thought she dislocated her elbow joint. She was treated for that by a practitioner called in the emergency, and he discharged her with a stiff arm, which he said he was unable to straighten. Dr. Cohen examined the arm, and found no dislocation at all. He asked her to report at the surgical department of the Polyclinic for verification of his opinion. She called, and Dr. Steinbach noted extreme spasm of the biceps, the tendons being like whip cords. Dr. Cohen applied a wooden magnet, and the spasm relaxed at once.

BATTERIES FOR ELECTRIC LIGHTING.—The following is part of a letter which has been sent to a local paper, and is worth consideration. It was written by Mr. E. Dixon, of Hull, in criticism of an article in the *Eastern Morning News*, entitled "The New Electric Light." The writer says:—"The heading is well chosen to attract the eye, but on reading one soon sees that it is not a question of a new electric light but simply of a new galvanic battery with which to generate the current. This form of electricity is not applicable to the arc light, but only to the small incandescent lamps. This new battery is being well puffed in the papers, and as a large company is about to be got up called 'The Yorkshire Company,' a short criticism may prove acceptable. Let us concede that the description of the construction of this battery is correct, and that its properties, viz., the steady and continuous generation of a large volume of current is eminently suitable for a certain kind of electric light, where the use of the dynamo machine or any of the forms of accumulators is not practicable. Let us even for the sake of argument concede that it is the best and cheapest battery yet invented, and it will be at once seen that I have no wish to run it down. What I wish to do is to caution those too credulous people who believe all they read in print. The less means they have of judging, the more readily do they believe any statement connected with a new invention. Before investing on the strength of any prospectus, experience teaches most of us to be a little cautious. The public often see only the bright side first, the other side they get better acquainted with by experience, after they have lost their money. I think in this case there are reasons for caution. We are told that zinc at £14 10s. is put into the battery, and after it has done its work a production is obtained, used for making paint, worth £20 per ton, and that there is therefore 'a large margin to go on.' Very little account is taken of the cost of caustic soda or of the roasting for an hour or so the precipitated metallic copper necessary to reproduce the oxide. We are told 'there is a large margin to go on,' and many naturally conclude that the battery business leaves a fine profit, so that the electric light is produced for something less than nothing. I meet many people who have this impression, from having read this and many similar articles that have appeared. Now, though a believer in miracles, I am not able to believe that the first article ever supplied to the public for nothing or produced at a profit is to be the electric light. To produce the electric light by any other battery than the one advertised is admitted by electricians to cost about *ninety times* as much as to produce it by steam power and the familiar dynamo machine. We are therefore asked to believe that this new battery will be something more than ninety times cheaper than any yet invented, besides other advantages. You will say there is 'a large margin for our—what shall we say?—confidence in the new undertaking.' Without wishing to be unkind, it sounds rather too good to be true. Most men will perceive at once that a fallacy lies somewhere, just as it always does and always will when perpetual motion is discovered. In this case, as might be supposed, we shall find it in 'the large margin' where we are told zinc at £14 10s. produces a valuable product oxide of zinc at £20 largely used for making paint. Now, the best oxide of zinc used for making paint is worth from £17 to £18, and is not produced by precipitation. I never heard of the precipitate being used for paint grinding, and should be much surprised to hear of any manufacturer buying it at £10. It is not necessary to take up more space with roasting the copper."

WILLOUGHBY SMITH.

SMITH, WILLOUGHBY, entered the service of the Gutta Percha Company in the year 1848, about which time Faraday first called attention to the wonderful electrical qualities of that then comparatively newly-discovered gum, gutta percha. Soon after this date the Gutta Percha Company commenced experimenting with a view to covering iron or copper wires with gutta percha for telegraphic or other electric purposes. In 1849 they had so far succeeded with these experiments that they undertook to supply thirty miles of copper wire covered with a thick coating of gutta percha, to be laid from Dover to Calais, with a view to practically demonstrating the feasibility of submarine telegraphy.

During the years 1849-50 Mr. Smith was busily engaged in the manufacture and laying of this line, an interesting account of which is given by him in his "Resumé of the Earlier Days of Electric Telegraphy," published in the *Journal* of the Society of Telegraph Engineers and of Electricians in September, 1881. The trouble and annoyance caused by the imperfect system of making the joints in the experimental line induced Mr. Smith to give this subject his special attention, and in the cable laid over the same course in the following year (in the manufacture and laying of which he was also engaged) he introduced a system of joint making which proved a great success, and in 1855 the present system of joining and insulating the conductor.

In 1852 he was engaged in the manufacture and laying of the Holyhead and Howth, Port Patrick and Donaghadee cables, and in the manufacture of the cables laid from Orford Ness to the Hague. In the same year Mr. Smith was also engaged in laying copper wires insulated with gutta percha in a trench dug in the "six-foot" of the Lancashire and Yorkshire Railway between Manchester and Liverpool. This was the first line possessed by the Magnetic Telegraph Company. In 1853 he had charge of the laying of ten copper wires—insulated separately with two coverings of gutta percha, then laid longitudinally together and bound with tarred hemp and placed in a wooden trough—in a trench made by the side of the old coach road from London to Manchester, and from Preston to Liverpool. In the June of that year the Gutta Percha Works were partly destroyed by fire, which caused a serious delay in the progress of this work. Early in 1854 the first cable to be laid in the Mediterranean was commenced. Mr. Smith had charge of the electrical department during its manufacture, and assisted Professor Wheatstone with his experiments on the retardation of signals through this cable while coiled at the works of Messrs. Glass, Elliott and Company, East Greenwich. These experiments were made for the purpose of verifying or correcting the results of similar experiments which had been made by Professor Faraday on lengths of the core of this cable at the Gutta Percha Company's works earlier in the same year. Mr. Smith took charge of the electrical department during the laying of this cable between Spezzia and Corsica, Corsica and Sardinia; and in the following year was similarly employed in the manufacture and laying of a cable between Sardinia and Bona. During the manufacture of this cable Dr. Whitehouse made experiments with it to obtain trustworthy data for giving suitable proportions for the core of an Atlantic cable which was then in contemplation. On Mr. Smith's return from this expedition he remained at home as electrician and manager of the wire department at the Gutta Percha Works, and at once commenced to prepare for the manufacture of 2,500 miles of core for a cable which was to be laid from Ireland to Newfoundland.

In 1857 Mr. Smith exhibited at the Polytechnic his electric railway signal, which was favourably noticed in the scientific journals at the time. By his arrangement the signal could be placed at any desired distance from a station, and yet the nature of the signal, whether red, green, or white, would be registered at the station where the man in charge had sole control over the apparatus. Mr. Smith has in his possession models which he made about the same time, illustrating how a train passing through a tunnel, or over any section of a line, would give its own signal on entering, and remove it on leaving the tunnel or section; also how trains running on the same line could communicate with each other, or any desired station on that line.

In 1851, after the manufacture of the single covered copper wire already referred to as having been laid from Dover to Calais, it was thought advisable to apply the gutta percha in two or more thin, instead of one thick covering; and to insure adhesion between these separate coverings coal tar naphtha was employed. But time showed that so strong a solvent of gutta percha was very prejudicial to its durability, and in 1858 Mr. Smith invented an insulating and adhesive compound suitable for application between each covering of the gutta percha, instead of the coal tar naphtha. This compound was soon adopted, and is in general use at the present time.

It had long been a source of complaint that while repairing submarine cables there was great difficulty in insulating the joint, owing to the water entering at the fault and traversing a considerable distance along the strand. To obviate this serious objection to strand conductors, Mr. Smith passed the centre wire of the strand through the compound before mentioned just before the other six wires were laid round it, the result being that not only did six inches of a strand so constructed resist the passage of water at a pressure of 1,000lb. per square inch, but that the compound filled the interstices of the strand, and thus made a more perfect adhesion between the conductor and the first covering of the gutta percha. This has proved of great value, and is now universally adopted.

In endeavouring to arrive at the right solution of the perplexing problem why cables, the electrical condition of which had been all that could be desired during manufacture, shipment, and laying, should develop faults of various resistance at various periods after submersion, Mr. Smith made a series of experiments with artificial faults served with tarred yarns, the same as the cores of cables were served, and submitted to various pressures of water. He found that, owing to the insulating properties of the tar, the faults did not develop themselves until after long submersion, in some instances extending over two years. To obviate this serious defect in the construction of cables, Mr. Smith proposed that tar and other insulating fluids should be abandoned, the serving being tarred only for the purpose of preserving it, and that it should be applied to the core thoroughly saturated with water, then coiled in tanks where it would remain in water. Then, should the core contain an incipient fault still undeveloped, when it passed the lay plate of the wire covering machine the pressure of the iron wires round the serving would force the water into the fault and at once develop it. This is known as the "wet serving" process, and has been adopted in the manufacture of all submarine cables.

In 1864 the works of Messrs. Glass, Elliott and Co., at Greenwich, and the Gutta Percha Company were formed into "The Telegraph Construction and Maintenance Company," Mr. Smith retaining his position at the Gutta Percha Works.

In 1865 the late Sir Richard Glass, the then managing director of the Telegraph Construction and Maintenance Company, requested Mr. Smith to accompany the "Great Eastern," and render assistance, if necessary, in the laying of the cable from Ireland to Newfoundland. It is matter of history that owing to the frequent appearance of faults, caused by the ends of the broken iron wires of the outer covering becoming disturbed and puncturing the gutta percha in the conductor, great difficulties were encountered, and, after laying 1,200 miles, and, while endeavouring to recover a fault, the cable parted. After many fruitless endeavours to recover the cable, the expedition returned to refit, but ultimately it was considered that the year was too far advanced to continue such operations in mid-Atlantic. Mr. Smith considered the electrical system employed on the occasion imperfect, inasmuch as it allowed faults, which were evidently caused on board, to pass miles astern before they were known to exist; he therefore devised an entirely new and original system, which would not only keep a continuous insulation test on

Digitized by Google

the whole of the cable, but also allow ship and shore to converse freely through it without interfering with either the insulation or continuity tests. The system met the hearty approval of all the gentlemen requested to examine and report upon it. Mr. Latimer Clark reported: "I have examined the system carefully, and have experimented upon it through upwards of a thousand miles of the Atlantic cable now on board the 'Great Eastern,' and I find it in every way suited for practical use; it allows of the free application of the various tests requisite during submergence of a long submarine cable, and it has the peculiar merit of giving an absolutely continuous test of insulation, and at the same time of enabling the tests for continuity of the conductor and the transmission of intelligence to be carried on uninterruptedly without the necessity for any change in the connections of the apparatus employed either on ship or shore."

We might quote Sir William Thomson and other eminent men, but the space at our disposal will not admit of our doing so. Mr. Smith has given a very interesting account of the system in his paper on "The Working of Long Submarine Cables," which he read before the Society of Telegraph Engineers and of Electricians, 12th February, 1879.

Early in 1866 Mr. Smith was appointed chief electrician to the T. C. and M. Co., and in that capacity was engaged on board the "Great Eastern" during the successful laying of the cable from Ireland to Newfoundland, and the recovery and completion of the cable lost the previous year. Mr. Smith's new system was adopted on that occasion and in the paper just referred to Mr. Smith states, "The whole worked remarkably well." During the fourteen days occupied in laying the cable from Ireland to Newfoundland 164 messages in all were sent and received between ship and shore, containing 6,437 words, or 30,059 letters. Early in the forenoon of each day interesting paragraphs from the morning papers were sent to the ship; these Mr. Smith posted outside the test room, with the heading "The 'Great Eastern' Telegraph." It was pleasing to see the great interest taken in this paper: the sailors, cable hands, firemen, &c., as they came off duty, would wait round the door of the electrical room, anxious to learn the home news before they retired for their well-earned rest.

On the completion of the cables, Mr. Smith applied his system to their working, and before he left the station at Heart's Content, to return home in the "Great Eastern," he had the pleasure of seeing a speed of thirteen words per minute pass through each cable.

Submarine telegraphy has made such rapid strides and has become so familiar to all that only those who remember the days of which we now write can fully appreciate the value of the work that was accomplished by the successful completion of telegraphic communication between England and America.

On the return of the "Great Eastern" the gentlemen who had achieved so much were justly *fêted*. The Liverpool Chamber of Commerce invited them to a banquet, at which the Right Hon. Sir Stafford Northcote, President of the Board of Trade, presided. During the evening the chairman read a letter from Lord Derby, in which he stated that Her Majesty had been pleased to direct that the honour of knighthood should be conferred upon Professor Thomson, Captain Anderson, and Messrs. Glass and Canning. Her Majesty further marked her approval of the public spirit and energy of the two companies by offering the dignity of a baronet of the United Kingdom to Mr. Lampson, deputy chairman of the original company, and to Mr. Gooch, M.P., chairman of the company which finally accomplished the great design. The American Chamber of Commerce, at Liverpool, had four massive gold medals struck, with appropriate designs on either side of each, and at a public banquet given in that city presented one to each of the following gentlemen:—Sir James Anderson, captain of the "Great Eastern;" Sir Samuel Canning, engineer of the expedition; Willoughby Smith, electrician to the expedition; and Cyrus W. Field, as chief of the originators of the enterprise.

Mr. Smith's system having proved so successful with the Atlantic cables, on his return from this expedition he was requested to apply it to the cable, then in bad condition, between Malta and Alexandria. In this work he was also successful, and has given the results of his labours in his paper, already referred to, on "The Working of Long Submarine Cables." In 1868 a cable was laid direct from Malta to Alexandria. Mr. Smith accompanied this expedition as electrician in charge, and employed the same system as that used on the Atlantic cables. On the completion of this line the first test message sent through it was at a speed of twenty-one words per minute.

On Mr. Smith's return to England what is known as the "French" Atlantic cable was commenced, and in the June of 1869 he was again on board the "Great Eastern" in charge of the electrical department. This cable was successfully laid from Brest to St. Pierre, but Mr. Smith returned home broken down in health, and was for three months incapacitated for business.

About this time the use of india rubber in place of gutta percha for insulating the conductors of submarine cables was being strongly advocated on account of its comparatively low specific inductive capacity; but, soon after Mr. Smith's restoration to health, he showed how the specific inductive capacity of gutta percha could be reduced to an equality with, if not below, that of india rubber. He submitted samples of core so manufactured to gentlemen eminently qualified to report upon them, and they reported that the specific inductive capacity of what was termed "Willoughby Smith's gutta percha" was 18 per cent. lower than that of ordinary gutta percha. This was an important discovery, as the amount represented a similar percentage of increased speed in conductors insulated with gutta percha.

This system of manufacture has maintained its ground, and india rubber for submarine cables is now never mentioned.

Mr. Smith has been intimately connected with the Society of Telegraph Engineers and of Electricians from its commencement, and he has communicated the following papers to that society:—"Underground Telegraphs," "The Effect of Light on the Electrical Qualities of Selenium," "The Working of Long Submarine Cables," "A Resumé of the Early Days of Electric Telegraphy," "Volta Electric Induction."

In 1882 he was elected its president, and in January, 1883, delivered his inaugural address, which is published in the society's *Journal*, and we would recommend all who take an interest in electrical science to study this address. The concluding remarks so please us that we cannot refrain from quoting them here:—"In conclusion, I would remark, especially to the younger members of this society, that it has always been my endeavour to follow the advice of an author, whose name I have forgotten, but who wrote, 'I find a frank acknowledgment of one's ignorance is not only the easiest way to get rid of a difficulty, but the likeliest way to obtain information; and therefore I practise it. I think it an honest policy. Those who affect to be thought to know everything often remain long ignorant of many things that others could and would instruct them in if they appeared less conceited.' The tendency of the present day appears to be to sacrifice much to the love of gain. We have an honourable calling; then let our endeavour and ambition be to guard it as such, and in so doing 'learn to labour and to wait' for that reward which is sure to crown the labours of the honest worker."

In June last Mr. Smith gave a lecture at the Royal Institution on "Volta and Magneto-Electric Induction," in which he propounded a new theory, and called in question the correctness of some of the results given by Faraday.

Mr. Smith is still electrician-in-chief to the Telegraph Construction and Maintenance Company, and also manager of their gutta percha works, Wharf-road.

MESSRS. WOODHOUSE AND RAWSON.—We are requested to state that although Messrs. Woodhouse and Rawson have transferred their manufacturing business at Cadley Hall Works, Hammersmith-road, to a limited liability company, this will not interfere in any way with the general business carried on by them at 11, Queen Victoria-street, as electric light contractors and suppliers of electrical goods.

ON RESISTANCE COILS FOR LARGE CURRENTS.

BY W. H. SNELL.

In the construction of resistance coils for large currents it is sometimes taken for granted that it is advantageous to make use of a metal having a high specific resistance. Hence either German silver or iron is usually employed for the purpose. If the coils are to be used for purposes of measurement German silver is, of course, indispensable on account of its small temperature coefficient. But for merely interposing a graduated resistance in the circuit, or in any case where the current happens to be constant, it may be shown that by employing the metal of lowest specific resistance we effect a very considerable economy in the total weight of metal required for a given resistance, and with proper arrangements also an economy of space. Under certain circumstances these considerations become of primary importance in arranging a set of coils.

The problem (which is, of course, one of elementary character, though I am not aware that it has been previously discussed) considered in this paper, is to obtain the constants of coils of any metal, joined either in series or in multiple arc, which under a given current shall not exceed a given temperature, and at that temperature shall have a given total resistance.

Let C = given current,
t = rise of temperature allowable,
R = required resistance.

Case I.—When the coils are in single series, and are therefore traversed by the whole current C,

Let d = diameter of wire in centimetres.
r = specific resistance (in ohms) of the metal at the total temperature $(T+t)$.
e = the "emissivity" for heat per square centimetre of surface of wire. Following Professor Forbes we may take its value (at a minimum) as $e = 0{\cdot}0002$.

We have then the well-known formula $C^2 = \frac{d^3 t \pi^2 e}{4 \times 0{\cdot}24 \times r}$

Putting $k = \frac{0{\cdot}96}{\pi^2 e}$ $\quad (\log k = 2{\cdot}686941)$,

we may write for the diameter of the wire in centimetres

$$d = r^{\frac{1}{3}} k^{\frac{1}{3}} \left(\frac{C^2}{t}\right)^{\frac{1}{3}} \quad \ldots\ldots \quad (1)$$

If L = length in centimetres of this wire, to give the required resistance R we have $L = \frac{Rd^2}{r}$ $\therefore$ from (1)

$$L = r^{-\frac{1}{3}} k^{\frac{2}{3}} \left(\frac{C^2}{t}\right)^{\frac{2}{3}} R \quad \ldots\ldots \quad (2)$$

If W = weight of this wire in grammes,
g = specific gravity of the metal, we have

$$W = L d^2 \frac{\pi}{4} g; \quad \therefore \text{ from (1) and (2)}$$

$$W = r^{\frac{1}{3}} k^{\frac{4}{3}} \left(\frac{C^2}{t}\right)^{\frac{4}{3}} \frac{\pi}{4} g R \quad \ldots\ldots \quad (3)$$

From these formulæ it appears that for coils having equal resistances at a given temperature, the *diameter* and *weight* is directly and the *length* inversely proportional to the cube root of the specific resistance of the metal at that temperature.

In (1) put $r^{\frac{1}{3}} k^{\frac{1}{3}} = a$,
„ (2) put $r^{-\frac{1}{3}} k^{\frac{2}{3}} = b$,
„ (3) put $r^{\frac{1}{3}} k^{\frac{4}{3}} \frac{\pi}{4} g = c$.

Then (diameter) $$d = a\left(\frac{C^2}{t}\right)^{\frac{1}{3}} \quad \ldots\ldots \quad (4)$$

(length) $$L = b\left(\frac{C^2}{t}\right)^{\frac{2}{3}} R \quad \ldots\ldots \quad (5)$$

(weight) $$W = c\left(\frac{C^2}{t}\right)^{\frac{4}{3}} R \quad \ldots\ldots \quad (6)$$

The values of the constants a, b, and c for copper, iron, and German silver are tabulated below; but the figures given are of value mainly for purposes of comparison, unless in any case the theoretical value of a coincides with some diameter on the wire gauge. Probably the results obtained are all somewhat too high, especially for smaller wires, as no allowance is made for convection or for the cooling influence of terminal masses. Table II., giving the constants for the other metals relatively to copper, is of most value. The specific resistance has been taken for 96 per cent. copper and for a total temperature $(T+t) = 80°C.$ $(= 176°F.)$. For any practical purpose, inasmuch as r appears in the form of its cube root, the value here assumed for r may be taken as constant within practical limits, whatever value be given to t. (In formulæ (4), (5), and (6) it will not, however, be well to assume a value for the term t itself and include it in the constant, because in the two latter it appears under a higher index.)

TABLE I.

	a		b		c	
	cm.	inches.	metres.	ft.	grammes.	lb.
Copper	·1034	·0407	... 47	154	... 343·5	0·76
Iron.....	·1854	·0730	... 26	86	... 552·0	1·22
German silver...	·2198	·0865	... 22	72·5	... 713·5	1·57

Copper being taken as unity, the ratios for the other metals are as follow:—

TABLE II.

	Diameter.	Length.	Weight.
Copper	1	1	1
Iron	1·8	0·56	1·61
German silver ...	2·125	0·47	2·08

Case II.—n coils joined in multiple arc. In this case, in order to obtain the same total resistance R, we must have for each coil a resistance n R. Nevertheless, under the required conditions, and owing to the increase of surface in proportion to mass, the total weight of metal required is less than when $n = 1$.

The current traversing each coil will be $\frac{C}{n}$. We therefore have from (4)

$$d_1 = a\left(\frac{C^2}{n^2 t}\right)^{\frac{1}{3}} = a\left(\frac{C^2}{t}\right)^{\frac{1}{3}} n^{-\frac{2}{3}}$$

$$\therefore d_1 = d\, n^{-\frac{2}{3}} \quad \ldots\ldots\ldots\ldots \quad (7)$$

Let L_1 = total length of the n coils
and l = length of each coil; then from (5)

$$l = b\left(\frac{C^2}{n^2 t}\right)^{\frac{2}{3}} n R = b\left(\frac{C^2}{t}\right)^{\frac{2}{3}} n^{-\frac{1}{3}} R$$

$$l = L n^{-\frac{1}{3}} \quad \ldots\ldots \quad (8)$$

and $$L_1 = n l \quad \therefore L_1 = L n^{\frac{2}{3}} \quad \ldots\ldots \quad (9)$$

Let W_1 = total weight of the coils, then

$$W_1 = L_1 d_1^2 \frac{\pi}{4} g \quad \therefore \text{ from (7) and (9)}$$

$$W_1 = L d^2 \frac{\pi}{4} g\, n^{-\frac{2}{3}}$$

$$\therefore W_1 = W n^{-\frac{2}{3}} \quad \ldots\ldots \quad (10)$$

Therefore from (7) (9) and (10) for any sets consisting of n coils of any metal joined in multiple arc, each set having the same total resistance, and proportioned so as to attain the same temperature under the same current, the diameter and total weight of the wire will be *inversely* proportional to $n^{\frac{2}{3}}$ and the total length will be *directly* proportional to $n^{\frac{2}{3}}$.

The following table gives the values of a, b, and c for copper for the first four values of n, giving results in centimetres, metres, and grammes respectively. The fourth column (b) gives the *total* length for n coils.

Digitized by Google

TABLE III.

n	n^2	Diameter. a	Length. b	Weight. c
1	1·00	·1034	47·0	343·5
2	1·59	·0651	74·5	216·5
3	2·08	·0497	98·0	165·0
4	2·52	·0410	118·5	136·5

The *ratios* of *a*, *b*, and *c* for the other metals compared with copper remain, of course, as already given in Table II.

APPARATUS FOR TESTING LIGHTNING CONDUCTORS.

BY C. AND E. FEIN, STUTTGART.

The electrical testing of lightning conductors is at present carried out in a manner more or less complete—generally the latter. As a rule the condition of lightning conductors is considered satisfactory if the needle of a common galvanometer, connected by wire with a battery, causes a deflection.

This examination only shows that the circuit is unbroken, or, if not, it permits of ascertaining the point where the circuit is interrupted; but it does not show the resistance of a lightning conductor. Still, such knowledge is of great importance, as the resistance should not exceed a certain amount. It is true that the efficient state of lightning conductors has been approximately estimated by the extent to which the needle is deflected; but this result is not trustworthy, the degree of deflection not being in direct ratio to the resistance of the circuit, and the elements usually employed not being sufficiently constant.

Another method is often adopted by which the actual resistance may be measured; but it requires many instruments, as well as a voluminous scale of resistances, to be substituted for the lightning conductor, so as to obtain a deflection equal to that of the latter, the resistance required for it being that sought. Apart from the indirectness of this method and the large volume of the whole apparatus, only experienced electrical engineers are able to use it, and the battery elements used must be very constant, for the results are incorrect if the strength of the current varies during the test.

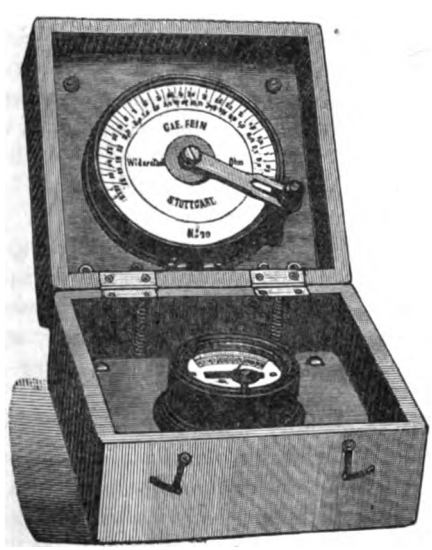

FIG. 1.

To overcome these drawbacks, the above-named firm has constructed apparatus, which permits of measuring the resistances of lightning conductors, in a simple and trustworthy manner, by a combination of the Wheatstone bridge with a sensitive galvanometer. These instruments, with all the accessories necessary for the test, are packed in two convenient cases; and they can be brought into action quickly and easily, so that the tests may be carried out correctly and without loss of time. The use of these instruments is very simple, so that anyone may employ them by attending to the directions.

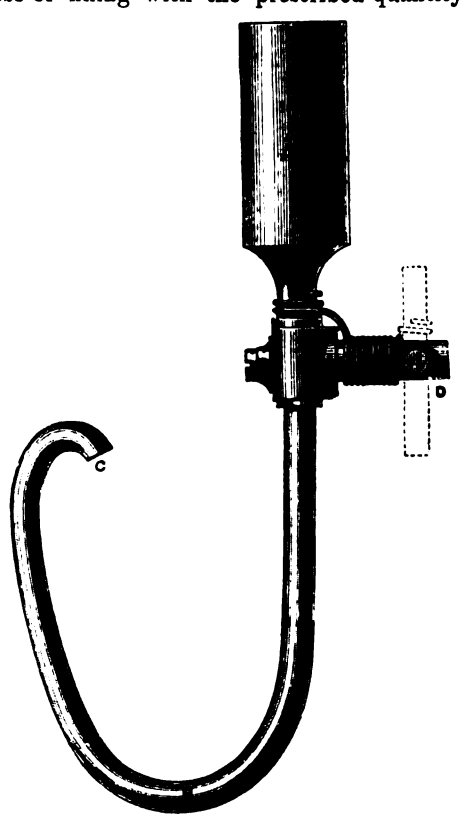
One case (Fig. 1) contains the battery, the leads, two good strong binding screws, a file to remove the coating of oxide from the lightning conductor, and a copper earth plate for testing the earth circuit. The battery cell is of india rubber, containing a bichromate of potash solution in which the zinc rod is immersed. The leads are small cables of fifty copper wires, well insulated and wound on two spools, by which they can be readily rolled up and unrolled. They have a high conductivity, and are very flexible, so that tests may be carried out in difficult situations.

Another case contains the measuring instruments proper, which consist of a correct galvanometer, with an arrangement to stop the hand at any given point, and a Wheatstone bridge with standard resistances, the wire of which is wound round a circular slate tablet, the sliding contact being changeable by a crank. The pitch-circle permits of a direct reading of the resistances between 0 and 25 ohms. This is sufficiently minute for such measures, because the resistance of the above ground circuit of a lightning conductor should not exceed 0·5 ohm, and that of the earth circuit not 20 ohms.

Messrs. Fein have now constructed this apparatus for several years, and guarantee its efficiency, as has been proved by all the tests made with their aid. It must, however, be borne in mind that such tests can only prove the conductibility of lightning conductors, and that it is important for the instruments acting properly that the circuit should also be properly tested.

A NEW FLUID INSULATOR FILLER.

We herewith illustrate a syphon recently designed by Mr. Wittkugel, of the Indo-European Telegraph Department, for the purpose of filling with the prescribed quantity of oil the



patent fluid insulators invented by Messrs. Johnson and Phillips.

A is a cup of the proper dimensions to hold the requisite quanity of oil; B, a tube, so curved as to bring the end C over the interior of the fluid chamber after being placed in position; D, a handle to open a tap, so that the oil may flow from the cup A through the tube B to the insulator. The tap is closed automatically, by means of a spring, upon the handle being released.

This apparatus will greatly facilitate the filling of fluid insulators, and is so extremely simple that a small boy might work it.

NOTICE.

We this week give the first of a series of Portraits from steel engravings, which we contemplate issuing from time to time. Every Subscriber should receive a copy with his paper, and any one not receiving the Supplement should communicate direct with the office. The steel engravings are supplementary to the more humble portraits from wood-blocks; but we trust that many eminent electricians will figure in both series.

THE ANGLO-AMERICAN BRUSH COMPANY.

The annual report of the ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION, a full reprint of which will be found in another part of this paper, is a document of considerable public interest at this juncture, besides being, as we should suppose, highly satisfactory to the holders of shares in that company. Its balance-sheet is, we believe, the first of its kind that has shown a leaning to the right side; at all events, of profits derived from actual work done. This very Company, or Corporation, as it prefers to be called, derived, as all the world knows, a large revenue—or perhaps we should rather say acquired large sums of money—from the sale of privileges to subsidiary companies. And so active was the demand for these privileges that the parent concern was enabled not only to do a good deal of its own work for less than nothing, but to figure on the market as a mine of fabulous wealth. Its shares were for a time at a high premium, and when they reached their highest possible the holders realised considerable fortunes by selling out. In this way, no doubt, the electric light "business" was worked at a profit, but in no other sense until now has there been any work or business done on profitable terms.

Last year, however, came the turning point with this as with all the other electric light companies, when it became evident that they must sober down to the humble functions of an industrial corporation, and abandon altogether the higher flights of financial speculation. They reduced their nominal capital, and started the year determined to work for their living. Their balance then was on the wrong side to the tune of sixteen hundred pounds, and they had to face a depressed condition of trade, which got worse rather than better as the year went on. Nevertheless they have passed through the ordeal safe in the possession of a net profit of over £4,000, after paying all standing charges and expenses, including the adverse balance of '83. The report furnishes no details of the character of the business done; but it amounted in the gross to nearly £17,000, a sum which, although ridiculously small compared with the capital invested, is highly encouraging as a beginning, and, all the circumstances considered, is better than might have been expected. No pretence is made of paying a dividend, what remains after reducing cost of goodwill, patents, &c., being carried to next account.

It is proof of the managers' fixed intentions to steadily develop their business that they have not hesitated to spend money on the improvement of their apparatus. To hold their own against competitors they must never relax their vigilance, nor grudge such outlay. But there is every temptation to be parsimonious in these particulars when times are bad; and the management has shown a wise foresight in keeping pace with invention, this being the surest way of laying a solid foundation for a remunerative business in the not far distant future. The new armature of the Brush machine has undoubtedly increased its efficiency, and the improved regulators for the lamps are well worth the money spent upon them. On the other hand, the economy displayed in legal expenses is not less gratifying. Some threatened lawsuits have been averted, and others that were pending have been arranged; "the corporation is now happily not involved in any litigation"—words which both this and every other electric light company would do well to get stereotyped for all future annual reports.

Of course a portion of the report is devoted to remarks on the adverse influence on electric lighting enterprise exerted by the Act of 1882. A good deal more might have been said; for, in truth, the Brush Company's vicissitudes, at all events for nearly three years, are in great measure due to the operation of that Act, the present report being, indeed, the best practical commentary upon it that we have yet seen. Here is a company with an excellent system, an energetic management, a competent staff, and ample capital; yet such have been the hindrances thrown in its way by legislation that its main business has consisted, apparently, of contracts for small installations, nowhere for lighting any district on a large scale. Its powerful influence has been brought to bear on the Board of Trade, and it has co-operated with the Committee which waited upon the President a short time ago. The Company insist, like everybody else, on a radical amendment of the Act, and express themselves sanguine of obtaining what they want in the forthcoming session of Parliament. We trust they may not be disappointed. The satisfactory point about their report is that they have made good progress with business, even outside the reach of the Act, and are evidently preparing themselves for largely increasing it. In this way,

Digitized by Google

we think, they are doing the best possible service to the cause by demonstrating the advantages of electric lighting, by showing that it can be worked profitably on ordinary commercial principles, and inferentially that it cannot be undertaken under the restrictions and penalties of the Act which was passed ostensibly to promote it. On the other hand, the comparative smallness of their profits, the largeness of the preliminary expenditure, and the cost of keeping up their appliances to the level of scientific and mechanical discoveries show how hardly the Act in its present shape would have borne upon electric lighting undertakers if they had accepted its conditions. Happily they have not; the public conscience will support them in this, we think; and the public demand for the light will in the long run help them to obtain better terms. Meanwhile their policy is to push private business as energetically as possible, but above all to supply nothing but the very best article procurable. The demand for it will depend chiefly upon the satisfaction it gives to their customers.

CORRESPONDENCE.

PERSONAL SAFETY AND ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I do not know that there is anything to add to what I have already said on this subject, except to explain my views on the measurement of the resistance of the body by means of alternating currents, and my "sweeping condemnation" of that process. Dr. Stone, page 223, says he has not heard before of its accuracy being questioned; but I questioned and condemned it in the first edition of my "Electricity," not by name possibly but in principle, as used for measuring the resistance of water, &c. But Dr. Stone, by his remark that my "suggestion that a wire resistance balanced against the body may act as a short-circuiting shunt rather than a fair derived circuit" shows that he has not perceived the real meaning of my objection, and though he says that I have given no proof, the Doctor has kindly supplied it for me. As a consequence I may be able to save him trouble and disappointment in the results of his proposed plan. I may add that his plan is not quite new; I have used it myself for measuring liquid resistance while getting rid of "polarisation." I described one form of the apparatus in my "Electricity," and it will be found p. 299 of the second edition or 194 of the first. To effect Dr. Stone's purpose, which is obviously to compensate the electrolytic polarisation of the body, he must use the liquid cell in one branch only; as he proposes to operate he will have merely added a liquid cell in each of the two branches to the body and the resistance instrument. He should insert in the branch which includes that measure an electrolytic cell whose electrodes should be nearly the same size as the conductors attached to the body, and its reactions nearly the same; then, having ascertained the resistance of this voltameter, he would add that to the other resistance measured. But even then he can never get a true result with intermittent or alternating currents. To explain why this process is useless (notwithstanding the names of Wheatstone and Kohlrausch) it is necessary to look into principles.

Now, what is *resistance?* The resistance of Ohm's formula is merely the reciprocal of the conducting capacity of the circuit, or a relation of *time* to other conditions which govern current. Its fundamental characteristic is that it is *invariable for all rates of current*, the same when measured under varying electromotive forces.

Well, Dr. Stone tells us that he gets variable measures when he uses 40 volts or 6 volts. So will any one who uses alternating currents to measure circuits in which there is either static or magnetic capacity, or electrolytic polarisation; because in all these cases we have either an extra E.M.F. or work in some form to deal with, as well as the normal resistance of the circuit. The result may be either a real increase of apparent resistance, or an apparent diminution of real resistance. It is this latter effect to which I referred (p. 203), though in describing the cause or action as that of a "shunt circuit," I am not quite sure that I used a term quite justifiable.

To make my meaning clear, let us conceive the branches of a bridge in one of which we place a condenser instead of an electrolyte or a human body; we then balance this in the opposite branch by a rheostat, giving a through wire circuit. We can thus obtain a balance either with continuous or alternating currents, but the measured *resistance* shown will be different, and will vary under the alternating current both with the E.M.F. and with the rate of intermittence. It is evident that we are balancing different things; in the wire circuit actual current passes in all cases, in the condenser it does not pass with the alternating current, but a succession of reverse charges on the plates represents a fictitious current. Exactly the same occurs when we balance an electrolyte or a human body against a measured wire circuit, and the apparent resistance thus obtained is a delusion. The proof of this is the fact noted by Dr. Stone that it varies with the E.M.F. used, and he would find it vary also with the same E.M.F. if he employed different rates of reversal.

This brings me to the question of *capacity* in two forms. Mr. Blakesley (p. 203) and I had obviously the same idea in our minds when he spoke of the electrostatic capacity of the body, and I compared the action to that across a set of condenser leaves, owing to the different conductivities of the liquids and the membranes and cell walls. Hence at every change or reversal of E.M.F. we must have corresponding "changes," as in a cable, with the corresponding mechanical attractions and nervous contractions. But besides this I use the term "conducting capacity," which Dr. Stone says he does not quite understand. Probably he means the same thing by "conductivity," but I prefer to leave that term to its common use as related to the specific properties of substances, and to express the conductivity of any defined circuit as its "conducting capacity," measured by the current it permits to pass under unit E.M.F. The reciprocal of this is the so-called "resistance," while the reciprocal of any measured R gives us the conducting capacity of the circuit; the term is, in fact, the dynamic analogue of the static capacity of a condenser. Now this *conducting capacity* of a circuit, measurable by the actual currents transmitted, is, I contend, the only true measure of the practical resistance, and includes any existent E.M.F. or work in any actual circuit.

I quite understand Dr. Stone's desire to get at the inner resistance of the body and separate that of the skin, and can sympathise with it as a matter of pure scientific investigation. I am also inclined to believe that the pure skin, and also the inner membranes and cell walls, are as nearly insulators as paper is, and that their actual conductivity is simply that of the liquids they contain, as in the case of porous jars; but from the practical point of view, and as to this question of danger, it seems to me not only useless but wrong to eliminate the skin resistance, simply because it is the usual practice of people to wear their skins, and to keep them in an ordinarily dry condition. No doubt a cut or abrasion greatly reduces the resistance, and might occasionally come into play in an accidental contact.
